EI provides the intrinsic emotional foundation for nursing students to effectively use AI, while confidence in their mastery of AI technology relies on AI self-efficacy (AILS). AILS is defined as an individual's belief in their ability to perform specific tasks, which directly influences nurses' willingness to adopt AI and their actual use of it [20]. Unlike general self-efficacy, AILS in nursing AI applications manifests as nursing students' confidence in mastering AI tools, overcoming technical challenges, and using them to solve clinical or learning problems [21]. This confidence in specific technical domains serves as the intrinsic motivation driving health care professionals to actively engage with, deeply explore, and persistently use AI tools [22]. Research indicates that enhancing nursing students' self-efficacy is crucial for alleviating psychological distress, ultimately improving their professional well-being and the quality of their future care [23]. In AI-enabled learning environments, Wang et al [24] indicate that self-efficacy and university support significantly enhance students' acceptance of AI-driven blended learning. Gao et al [25] further confirm that integrating AI chatbots into writing instruction can enhance students' AI self-efficacy. Lyu and Salam [26] also indicate that AI-driven personalized learning can enhance students' self-efficacy, motivation, and digital literacy. Additionally, high levels of AILS significantly predict nursing students' willingness to adopt AI technologies and the depth of their usage, thereby enhancing professional growth and adaptability in the rapidly evolving health care field [8].

Thus, EI and AILS jointly constitute the 2 core psychological factors influencing the development of AS among nursing students. EI ensures nursing students maintain essential emotional insight and empathy when interacting with AI and applying it in patient care, thereby providing the necessary human touch to technological implementation. Meanwhile, AILS provides the psychological drive to explore and use AI technologies, motivating students to transform potential technological advantages into realistic nursing capabilities [17]. To systematically guide and cultivate this complex psychological capability system, this study introduces an emerging theoretical framework—the NUR.S.E.S. framework [17]. This framework, recently proposed by Hoelscher and Pugh [27], aims to establish a structured pathway for developing AS within the nursing profession. Compared to generic technology adoption models or general educational technology frameworks, its novelty lies in deeply integrating the development of AS with the humanistic care, ethical responsibility, and clinical leadership inherent to the nursing profession, thereby better aligning with the contextual needs of nursing education. It is an acronym representing 6 core components:

- Navigate AI basics: promote understanding of AI fundamentals as a leadership responsibility critical to patient safety.
- Use AI strategically: purposefully apply AI tools to enhance care quality, safety, and outcomes.
- Recognize AI pitfalls and guide balanced approaches to innovation and risks such as bias, overreliance, and inaccuracy.
- Skills support: advocating for skill enhancement and professional development to prepare for AI integration in nursing.
- Ethics in action: guiding ethical AI use in nursing by promoting transparency, fairness, and accountability.

XSL•FO
RenderX

- Shape the future: directing AI implementation toward outcomes that align with nursing values and advance care equity.

This framework provides nursing educators with a forward-looking theoretical foundation rooted in nursing values, guiding students to develop their humanistic care, critical thinking, and ethical judgment capabilities simultaneously while mastering technical skills. This study used the NUR.S.E.S. framework, marking its first application in nursing education both domestically and internationally. Its internal structure clearly corresponds to core constructs such as EI (corresponding to the E and S dimensions), AILS (corresponding to the S dimension), and AS (corresponding to the N, U, R, and E dimensions), providing a structurally coherent and contextually relevant theoretical foundation for systematically analyzing the complex system formed by these variables.

As a cutting-edge, data-driven approach, network analysis transcends traditional linear assumptions to reveal intricate interactions among variables and precisely pinpoint their relative importance within a system [21]. This method provides a unique, systematic perspective for visualizing and quantifying the dynamic relational structure among EI, AILS, and AS [28]. By analyzing the interrelationships among variables, network analysis not only maps each measurement indicator to the theoretical dimensions of the NUR.S.E.S. framework but also tests whether the framework's predefined dimensional divisions align with the actual patterns of variable associations observed in the data. Specifically, it examines whether variables within the same framework dimension are closely interconnected in the relational network and whether there are significant, unexpected associations between different dimensions, thereby providing empirical support for the framework's validity [29].

Therefore, the objective of this study is to systematically analyze the complex network relationships and underlying mechanisms among EI, AILS, and AS based on the NUR.S.E.S. framework. By constructing a psychological network model, this study aims to identify factors that are associated with nursing students' AS, thereby providing precise targets for educational interventions. We plan to conduct a survey of nursing students at a Chinese university to gain an in-depth understanding of their practical application of AI, including EI, AILS, and AS. By analyzing these findings, we aim to identify existing challenges and provide crucial theoretical foundations and practical guidance for cultivating future nursing professionals who can master intelligent technologies while upholding humanistic care.

Methods

Objects and Methods

A total of 982 full-time undergraduate nursing students from a particular university were selected as research participants. Among them, 117 were male, and 865 were female, with ages ranging from 18 to 24 years (mean age 21.18, SD 0.51 years). The inclusion criteria were (1) full-time undergraduate nursing students enrolled at the university; (2) students who had encountered or used AI-related technologies or tools in their daily studies or lives; and (3) voluntary participation in the experiment with signed informed consent and confidentiality agreements. Exclusion criteria applied to students on formal leave or extended sick leave during data collection. Participants could withdraw freely without affecting their studies or academic performance.

Ethical Considerations

The research procedures have been approved by the Ethics Review Committee of Xijing University (Approval number: XJU-202502). Participants' privacy has been protected. All participants provided written informed consent. No harm was inflicted upon participants. All nursing students had the right to choose whether to participate in this study. Data were securely stored and encrypted.

Instruments

General Demographic Questionnaire

The research team independently developed a questionnaire to collect basic information. This survey aims to systematically examine key social-demographic factors that may influence research outcomes, primarily covering age, gender, home address, prior experience as a student leader, academic year, and average frequency of use of electronic devices and AI tools.

EI Scale

The EI Scale developed by Schutte et al [30] was used to assess students' EI levels. The Chinese version was revised by the Chinese psychologist Caikang [31]. This version has demonstrated good reliability and validity among Chinese students. This scale comprises 4 dimensions, including emotional perception (12 items), self-emotional management (8 items), managing others' emotions (6 items), and emotional application (7 items), totaling 33 items. A 5-point Likert scale was used to score, ranging from "Strongly Disagree" to "Strongly Agree," with values from 1 to 5. Higher scores indicate a higher level of EI among students. The Cronbach α coefficient for the full scale was 0.90, and the test-retest reliability Cronbach α coefficient was 0.78. In this study, the Cronbach α coefficient for the scale was 0.959.

AILS Scale

The AILS scale, developed by Wang et al [32], is used to assess users' self-efficacy when using AI technologies and products. The scale comprises 4 dimensions, including assistance (7 items), anthropomorphic interaction (5 items), comfort with AI (6 items), and technical skills (4 items), totaling 22 items. Scoring uses a 7-point Likert scale from "Strongly Disagree" to "Strongly Agree," with values ranging from 1 to 7. Higher scores indicate greater levels of AILS among users. Confirmatory factor analysis resulted in $\chi^2_{196}=1.984$; comparative fit index (CFI)=0.941; Tucker-Lewis index (TLI)=0.930; root-mean-square error of approximation (RMSEA)=0.079; and standardized root-mean-square residual (SRMR)=0.071. Cronbach α coefficient in this study was 0.953.

AS Scale

The AS Scale was developed by Wang and Chuang [33]. The scale comprises 4 dimensions, including awareness (3 items), usage (3 items), evaluation (3 items), and ethics (3 items). It is

XSL•FO
RenderX

based on a 7-point Likert scale ranging from "Strongly Disagree" to "Strongly Agree," with values ranging from 1 to 7, respectively. Higher scores indicate greater AS among individuals. Confirmatory factor analysis yielded the following indices: CFI=0.99, TLI=0.99, GFI=0.98, RMSEA=0.01, SRMR=0.03. The Cronbach α coefficient for the full scale was 0.830, while the Cronbach α coefficient in this study was 0.864.

Correspondence Table Between the NUR.S.E.S. Framework and Questionnaire Measurement Dimensions

Guided by the theoretical framework of NUR.S.E.S., this study establishes conceptual mappings between the 6 core competency dimensions of the framework (navigate, use, recognize, skills support, ethics in action, and shape the future) and their corresponding measurement variables. This mapping aims to structure the AS of nursing students as defined by the framework into measurable psychological and competency indicators, thereby providing a theoretical basis for subsequent network analysis and testing the intrinsic interrelationships among the framework's components.

Theoretical Rationale for the Mapping Between NUR.S.E.S. Components and Measured Variables

Overview

The mapping shown in Table 1 follows from the conceptual definitions of each NUR.S.E.S. component as originally articulated by Hoelscher and Pugh [27], combined with established theoretical and empirical literature in nursing education, EI, and self-efficacy research.

XSL•FO
RenderX

Table . Correspondence table between the NUR.S.E.S. framework and questionnaire measurement dimensions.

Framework letters	Representative of core variables	Dimensions corresponding to the questionnaire	Dimensional implications	Mapping dimensions
N	Navigate AI[a] basics	Awareness	• Basic understanding of fundamental AI concepts, application scenarios, and its impact on the nursing field.	"Navigate AI basics" emphasizes initial exploration and foundational understanding of the field of AI. Only by acquiring this foundational understanding can students freely explore the AI knowledge system; therefore, the "awareness" dimension has been selected to measure this ability.
U	Use AI strategically	Use	• The ability to operate and apply specific AI tools in practical nursing education, research, or simulated scenarios.	"Use AI strategically" focuses on practical application. This dimension directly assesses students' ability to apply AI as a tool in specific scenarios, reflecting the practical aspect of "use."
R	Recognize AI pitfalls	Evaluation	• Critically examine and evaluate the accuracy and reliability of AI-generated information.	"Recognizing AI pitfalls" requires critical thinking to identify the limitations and risks of AI. The "evaluation" dimension is precisely the core competency involved in assessing and discerning information, and it aligns closely with the requirement to identify flaws.
S	Skills support	Technical Skills Assistance	• Technical skills: confidence in one's ability to learn and master AI technology itself. • Assistance: believe that AI can serve as an effective tool to assist in completing learning or work tasks.	• "Skills support" comprises 2 aspects: first, confidence in mastering AI skills themselves (technical skills); and second, trust in AI as a supportive tool (assistance). These 2 dimensions together underpin students' self-efficacy at the skills level.

XSL•FO
RenderX

Framework letters	Representative of core variables	Dimensions corresponding to the questionnaire	Dimensional implications	Mapping dimensions
E	Ethics in action Emotional Intelligence (EI)	Ethics, Emotional Perception, Self-emotion Management, Managing Others' Emotions, Emotional Application	• Ethics: understand and adhere to ethical standards such as privacy and fairness involved in the use of AI in nursing practice. • Emotional perception: accurately recognize your own and others' emotional states. • Self-emotion management: the ability to regulate and control one's own emotions. • Managing others' emotions: the ability to influence and regulate others' emotions. • Emotional application: use emotional information to aid in thinking and problem-solving.	"Ethics in action" emphasizes the application of ethics in real-world nursing settings. EI as a whole construct is a foundational capacity for ethical practice, including perceiving, managing, and utilizing emotions. The 4 subdimensions of EI (EI1-EI4) are collectively used to measure EI, not to be split into other letters of the NURSES framework. The network analysis treats these 4 subdimensions as nodes belonging to the same EI community, which supports their theoretical coherence. Therefore, mapping all 4 EI subdimensions to the E dimension reflects the role of EI as a holistic supporter of ethics in action, not a forced segmentation.
S	Shape the future	Comfort with AI, Anthropomorphic Interaction	• Comfort with AI: feeling relaxed and at ease when interacting with AI, without anxiety or a sense of threat. • Anthropomorphic interaction: tends to engage in natural communication with AI in a manner similar to human interaction.	"Shape the future" embodies students' open and proactive approach to leading the development of AI in the field of nursing. Comfort with AI reflects their level of acceptance, while anthropomorphic interactions demonstrate their willingness to collaborate with machines; together, these 2 factors form the psychological foundation for actively shaping the future of nursing.

[a]AI: artificial intelligence.

Navigate AI Basics (N)

Hoelscher and Pugh [27] define this component as promoting understanding of AI fundamentals as a leadership responsibility critical to patient safety. In operational terms, foundational knowledge of AI concepts and applications constitutes the prerequisite for any further engagement with AI technologies [34]. Accordingly, the awareness dimension of the AS Scale [33], which assesses students‘ understanding of basic AI concepts, application scenarios, and potential impacts, serves as a direct measure of this component.

Use AI Strategically (U)

This component concerns the purposeful application of AI tools to enhance care quality, safety, and outcomes [27]. Strategic use implies not only familiarity with AI but the ability to operate and apply specific AI tools in practical nursing education, research, or clinical scenarios. The Use dimension of the AS Scale [33], which captures students' self-reported ability to work with AI tools in task-specific contexts, directly corresponds to this component.

Recognize AI Pitfalls (R)

Hoelscher and Pugh [27] emphasize that balanced approaches to innovation must include recognition of risks such as bias, overreliance, and inaccuracy. This critical evaluative competency is captured by the evaluation dimension of the AS Scale [33], which assesses students' ability to critically examine and judge the accuracy and reliability of AI-generated information.

Skills Support (First S)

The skills support component advocates for skill enhancement and professional development to prepare for AI integration in nursing [27]. This component encompasses both the confidence in one's ability to learn and master AI technology itself and the belief that AI can serve as an effective tool to assist in completing learning or work tasks. The AILS Scale [32] operationalizes these 2 facets through its technical skills and assistance dimensions, respectively, drawing on Bandura's broader theory of self-efficacy as domain-specific confidence

XSL•FO
RenderX

in one's ability to execute courses of action required to achieve desired outcomes [20].

Ethics in Action (E)

This component guides ethical AI use in nursing by promoting transparency, fairness, and accountability [27]. Importantly, ethical action in nursing requires not only knowledge of ethical principles but also the emotional capacities that underpin moral sensitivity and compassionate care. A substantial body of nursing literature demonstrates that EI—the ability to perceive, understand, manage, and use emotions—is positively associated with ethical sensitivity and moral reasoning in both nursing students and practicing nurses [8,15,31,35]. For example, Liu et al [36] found that EI mediates the relationship between empathy and moral sensitivity in Chinese student nurses, suggesting that emotional competence is not separate from but foundational to ethical practice [1]. The Schutte EI Scale [30], which measures 4 dimensions of EI (perception of emotion, self-emotion management, managing others' emotions, and emotional application), was therefore selected to capture the emotional competence component of ethical action. These 4 subdimensions are treated as a single conceptual community in the network analysis, consistent with the holistic contribution of emotional competence to ethical practice.

Shape the Future (Second S)

The final component directs AI implementation toward outcomes that align with nursing values and advance care equity [27]. Proactive, leadership-oriented engagement with AI presupposes that nurses feel psychologically comfortable with AI technologies and are willing to engage with them in a natural, quasisocial manner. Positive affective attitudes toward AI, including low anxiety and high comfort, have been identified as psychological prerequisites for adoption and sustained use in health care and educational contexts [21,37,38]. The AILS Scale captures these prerequisites through its comfort with AI and anthropomorphic interaction dimensions [32], which assess relaxed, nonanxious engagement with AI and the tendency to interact with AI in a human-like, conversational manner. These dimensions do not directly measure leadership behaviors but rather the psychological foundation without which proactive shaping of AI's future in nursing is unlikely to occur.

This mapping provides a theoretically grounded operationalization of the NURSES framework into measurable psychological and competency variables, enabling empirical examination of the interrelationships among its 6 components through network analysis. The mapping is not intended as an exhaustive or exclusive operationalization but as a starting point grounded in existing validated instruments and established theoretical links.

Data Collection

Researchers (XF and JW) contacted class administrators at target institutions via social media (WeChat; Tencent Holdings Limited). After explaining the study objectives and procedures and obtaining permission, they joined the corresponding class groups. Study information was disseminated through these class groups. Potential participants voluntarily confirmed their participation online after reading the informed consent form. The research team screened applicants based on predetermined inclusion and exclusion criteria. Students meeting the criteria were invited to participate in the survey. To facilitate organization and enhance response efficiency, researchers distributed electronic questionnaire links uniformly in classrooms during after-school hours. Data collection occurred from September 25 to September 28, 2025, using the online survey platform "WJX" for questionnaire distribution and retrieval. Participants independently completed the questionnaire after clicking the link and could exit at any time during the process. Completing the full questionnaire took an average of 10 - 15 minutes. A total of 986 questionnaires were distributed, with 982 returned. Platform settings ensured only fully completed questionnaires were recorded as valid submissions, eliminating incomplete submissions from being counted. Verification confirmed that returned questionnaires were valid. Data from 982 participants were ultimately analyzed, yielding a valid response rate of 99.59%.

Data Analysis

Descriptive statistics were calculated using SPSS (version 25.0; IBM Corp), with means and SDs for continuous variables and frequencies (percentages) for categorical variables. All continuous variables underwent normality testing in this study, and the results indicated that their distributions were generally normal [39].

Network analysis was performed using R (version 4.3.0; R Core Team). In 2-tailed tests, $P<.05$ was considered statistically significant. A Gaussian graph model was selected to construct the network structure using the R package "*qgraph*" [37]. To reduce spurious correlations and obtain a simplified network, the graph minimum absolute contraction and selection operator was used. The graph minimum absolute contraction and selection operator implements regularization techniques to constrain small partial correlations to zero, effectively eliminating potential false positive edges and yielding sparse, interpretable network structures [40]. To avoid overfitting and determine optimal tuning parameters, an extended Bayesian information criterion model is used to select the best-fitting model. This approach ensures that only the most robust and meaningful connections are retained in the final network.

In a network, nodes represent variables, and edges between 2 nodes represent the unique relationship between them, controlling for the influence of other nodes. Red and blue edges denote negative and positive correlations, respectively. The thickness of the edges corresponds to the strength of the association; thicker edges indicate stronger correlations [41]. The R package "*qgraph*" is used to calculate the strength, proximity, and betweenness centrality of nodes in a network [37]. Strength is defined as the sum of the absolute values of the edge weights connecting a node to all other nodes. Previous studies have shown that strength is the most stable and interpretable centrality measure in networks [42]. Compared to other centrality measures such as closeness and betweenness centrality, strength is more suitable for evaluating the importance of nodes [43]. Therefore, this study adopts strength as the centrality metric, with nodes exhibiting the highest strength

XSL•FO
RenderX

values being regarded as the most influential nodes within the network.

Additionally, the R package "*networktools*" was used to calculate bridging strength and identify potential bridging nodes [44]. Bridging strength refers to the sum of the absolute values of the edge weights connecting a node to other community nodes, indicating the node's importance to other communities. Nodes with the highest bridging strength values are considered bridging nodes within the network. Bridging nodes connect multiple domains, meaning interventions targeting these nodes can simultaneously impact multiple domains, which maximizes the effectiveness of the intervention.

Use the R package "*mgm*" to calculate the predictability for each node [45]. Predictability is a metric that reflects the extent to which the variance of a specific node can be explained by all its neighbors in the network. Nodes with high predictability are susceptible to the influence of their neighboring nodes.

The R package "*bootnet*" assesses the accuracy and stability of networks [46]. First, the accuracy of edge weights (the number of bootstrap samples is 1000) was examined by calculating their 95% CIs using nonparametric bootstrapping. Second, the stability of the network model is assessed using the case deletion procedure and the correlation stability (CS) coefficient, which indicates the proportion of samples that can be excluded from the analysis while maintaining at least 0.7 correlation with the original sample. According to network analysis guidelines, the CS coefficient should not fall below 0.25, and a value above 0.50 indicates sufficient stability [47]. Finally, a self-assessment method was used to conduct a difference test, examining variations in edge weights, node strengths, and node bridge strengths.

Results

General Information for Undergraduate Nursing Students

A total of 982 graduate nursing students were included in the statistical analysis, with their characteristics listed in Table 2. The mean age of participants was 21.7 years, and the vast majority (865/982, 88.1%) of participants were female. Among participants, 511 out of 982 (52.0%) resided in rural areas. The number of students in the first, second, third, and fourth years was 246 out of 982 (25.1%) participants, 242 out of 982 (24.6%) participants, 251 out of 982 (25.6%) participants, and 243 out of 982 (24.7%) participants, respectively. Among the 982 undergraduate nursing students, daily active use of GenAI tools was reported as follows: 22 out of 982 (2.2%) participants rarely used them, 608 out of 982 (61.9%) participants used them several times weekly, 297 out of 982 (30.2%) participants used them 3 - 5 times daily, and 55 out of 982 (5.6%) participants used them more than 5 times daily.

Table . General information on nursing undergraduates.

Statistical variable	Frequency, n (%)
Sex	
Male	117 (11.9)
Female	865 (88.8)
Age (years)	
<18	42 (4.3)
18-20	733 (74.6)
20-22	204 (20.8)
≥22	3 (0.3%)
Family residence	
Townships	471 (48.0)
Rural	511 (52.0)
Have you ever served as a student leader?	
Yes	479 (48.8)
No	503 (51.2)
Grade level	
Freshman year	246 (25.1)
Sophomore year	242 (24.6)
Junior year	251 (25.6)
Senior year	243 (24.7)
The average daily time spent using electronic devices (such as smartphones, computers, tablets, etc) is approximately (hours)	
<2	42 (4.3)
2-4	291 (29.6)
4-6	439 (44.7)
6-8	161 (16.4)
>8	49 (5.0)
On average, how often do you actively use AI[a] tools (such as ChatGPT [OpenAI], Wenxin Yiyan [Baidu], Deepseek [DeepSeek Artificial Intelligence Co, Ltd], etc) each day?	
Hardly ever used	22 (2.2)
Several times a week	608 (61.9)
3-5 times daily	297 (30.2)
>5 times a day	55 (5.6)
What is your primary purpose for using AI tools?	
Learning (such as researching information, assisting with homework, etc)	929 (94.6)
Entertainment and Leisure (such as smart chatbots, image/music generation, and video/audio recommendations)	468 (47.7)
Daily life (such as planning itineraries and obtaining health advice)	615 (62.6)
Work efficiency (eg, report writing, PowerPoint [Microsoft Corp] creation, data analysis)	595 (60.6)
Social needs (such as helping edit Moments captions and recommending chat topics)	336 (34.2)
Others	12 (1.2)

Descriptive Statistics of Variables (List in Table 3)

Descriptive statistics for nursing undergraduates' EI, AILS, and AS are presented in Table 3. Normality tests confirmed that all variables were approximately normally distributed. Data were described using mean (SD). SDs fell within normal ranges, with no outliers. Notably, "Emotional Perception (EI1)" demonstrated the highest predictive power and served as the critical component of the entire network.

Table . Descriptive statistics of emotional intelligence, AI self-efficacy, and AI literacy variables among nursing undergraduates (n=982).

Variable	Name	Mean (SD)	Expected influence	Bridge expected influence	Predictability
Emotional intelligence	EI[a]	3.57 (0.55)			
Emotional perception	EI1	3.41 (0.54)	1.248	0.427	0.832
Self-emotion management	EI2	3.51 (0.56)	1.016	0.118	0.788
Managing others' emotions	EI3	3.67 (0.61)	1.099	−0.006	0.801
Emotional application	EI4	3.68 (0.62)	1.355	−0.024	0.840

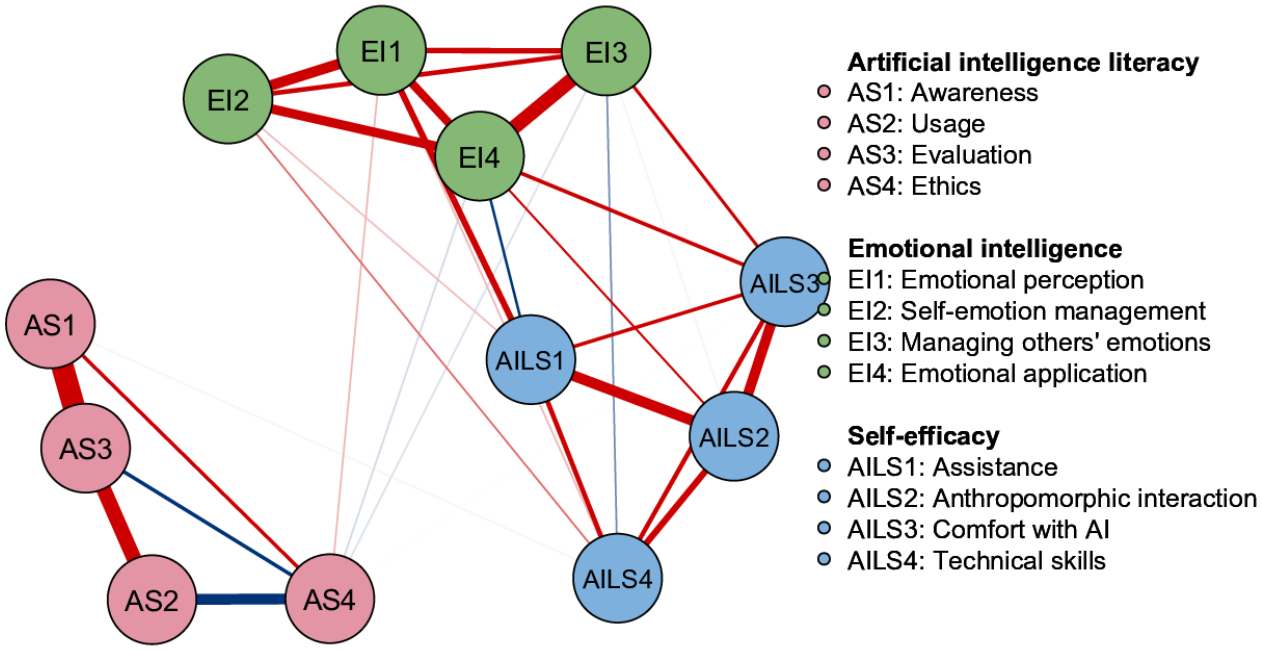
[a]EI: emotional intelligence.

[b]AI: artificial intelligence.

[c]AILS: AI self-efficacy.

[d]AS: AI literacy.



Network Analysis of EI, AILS, and AS Among Nursing Undergraduates

Figure 1 illustrates the network structure of EI, AILS, and AS among undergraduate nursing students. Node colors represent theoretical constructs: blue=AILS, green=EI, and red=AS. Letters on nodes denote dimension codes. Red indicates positive correlations; blue indicates negative correlations. Thicker lines denote stronger connections. Of the 66 possible connections, 54 (81.82%) were nonzero, and the network density was 0.82, indicating that the variables were generally closely interconnected within this sample. Among these, 41 were positive correlations and 13 were negative correlations. From the perspective of community structure, the nodes are primarily clustered into 3 distinct communities based on theoretical constructs, including emotional intelligence (EI1-EI4), AI self-efficacy (AILS1-AILS4), and AI competence (AS1-AS4). Connections within each community are relatively dense, while cross-community connections are relatively sparse, which is largely consistent with the dimensional divisions of the NURSES framework. Stronger connections primarily occurred within dimensions rather than between them. The 3 strongest intradimensional connections were EI4 (emotional use)-EI3 (managing others' emotions), AS3 (assessment)-AS1 (awareness), and AILS2 (anthropomorphic interaction)-AILS1

XSL•FO
RenderX

(assistance). The strongest interdimensional connection was between EI1 (emotional perception) and AILS1 (assistance). All edge weights (association strengths) are listed in Table 4.

Figure 1. Network analysis of emotional intelligence (EI), AI self-efficacy (AILS), and AI literacy (AS) among nursing undergraduates. Node colors represent theoretical constructs: blue=AILS, green=EI, and red=AS. Letters on nodes denote dimension codes. Red indicates positive correlations; blue indicates negative correlations. Thicker lines denote stronger connections. AILS: artificial intelligence self-efficacy; AS: AI literacy; EI: emotional intelligence.

[l]AS4: ethics.

Node Centrality Measures

The standardized estimates of centrality indicators for factors influencing EI, AILS, and AS among nursing undergraduates are shown in Figure 2. Emotional use (EI4) and assessment (AS3) exhibit the highest strength centrality, indicating that these 2 variables showed the highest strength centrality, indicating they are highly connected within the network. Emotional perception (EI1) and ethics (AS4) exhibited the strongest mediating centrality, signifying their pivotal bridging role in network information transmission with potent moderating capacity; emotional perception (EI1) and awareness (AS1) also demonstrated the most prominent proximity centrality, reflecting their highest information transmission efficiency and accessibility within the network. Stability tests for network centrality metrics revealed correlation stability coefficients of 0.749, 0.749, and 0.361 for node strength, intermediary centrality, and closeness centrality, respectively (see Figure 3). This indicates robust stability for these centrality measures, with node strength demonstrating the highest stability.

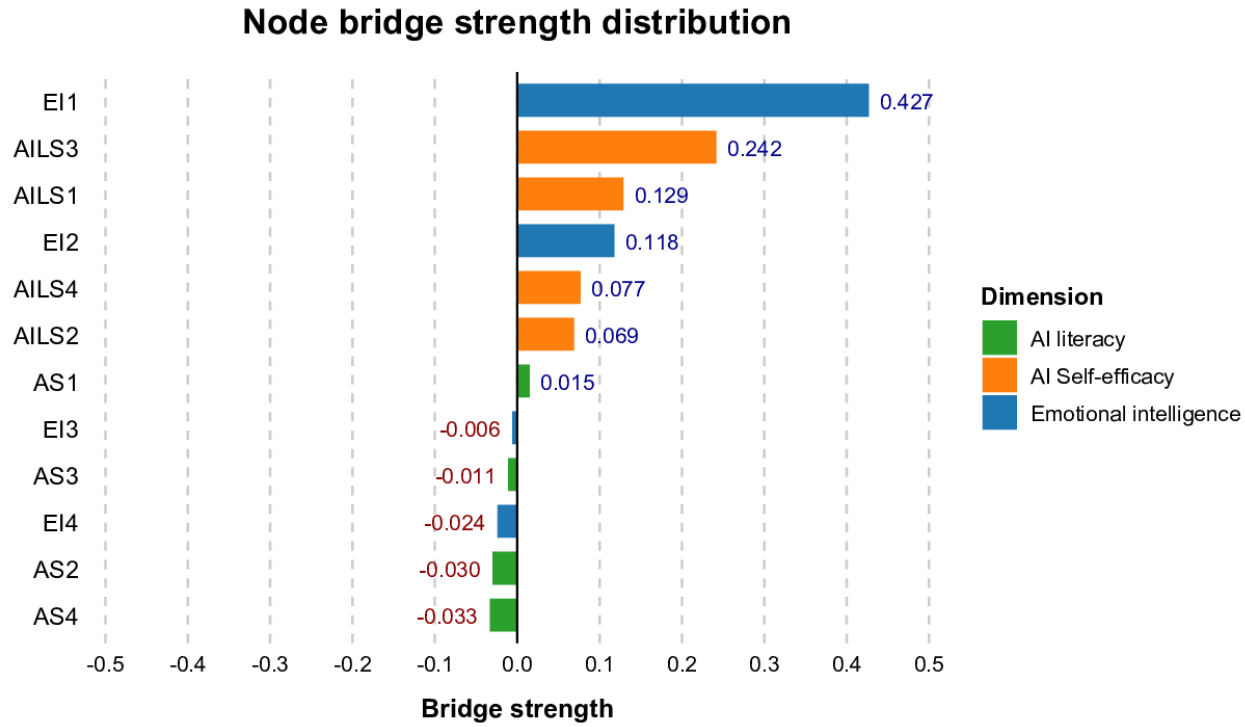
Edge Accuracy

The accuracy of edge weights was estimated using nonparametric bootstrapping. Results indicate that the 95% CIs for edge weights in the network are narrow, suggesting that the estimated edge weights in this study are highly precise (Figure 4).

Figure 4. Guiding edge weights for emotional intelligence, artificial intelligence (AI) self-efficacy, and AI literacy among nursing undergraduates with 95% CIs.



Node Bridge Strength

Figure 5 displays the bridge strength for each node. EI1 “Emotion Awareness” (bridge strength=0.427) exhibits the highest bridge strength, followed by ALS3 “Comfort with AI” (bridge strength=0.242), ALS1 “Assistance” (bridge strength=0.129), and EI2 “Self-Emotion Management” (bridge strength=0.118), suggesting they may serve as bridging nodes in this network.

Figure 5. Depicts the bridge strength (z-score) of each node in the network. AILS1: assistance; AILS2: anthropomorphic interaction; AILS3: comfort with AI; AILS4: technical skills; AS1: awareness; AS2: usage; AS3: evaluation; AS4: ethics; EI1: emotional perception; EI2: self-emotion management; EI3: managing others' emotions; EI4: emotional application.

Discussion

Principal Findings

This study is the first to use network analysis methods within the NUR.S.E.S. framework to examine the associations among EI, AILS, and AS among undergraduate nursing students. The network analysis identified that emotion use (EI4) and assessment ability (AS3) showed the highest strength centrality, indicating their prominent positions within the network. Emotion perception (EI1) had the highest bridge strength, suggesting it may serve as a connecting node between the EI domain and the AILS and AS domains. These findings provide insights into the psychological mechanisms underlying the development of AS among nursing students, offer a concrete explanation of how the 6 dimensions of the NURSES framework interact at the psychological level, and provide a critical foundation for the future development of targeted, comprehensive interventions that address the full spectrum from emotional foundations to technical confidence.

Overall Characteristics of EI, AILS, and AS

This study conducted a descriptive analysis of nursing students' EI, AILS, and AS. Results indicate that undergraduate nursing students' AILS (mean 4.68, SD 0.78) and AS (mean 4.60, SD 0.59) were generally at a moderately high level, while EI (mean 3.57, SD 0.55) scored relatively low. This situation highlights a key phenomenon: nursing students possess strong confidence in their ability to learn and master AI technologies and have established a foundational level of AS. However, the development of their EI has not kept pace, consistent with the findings of Bewersdorff et al [38]. From a specific-dimension perspective, within AILS, the "Comfort Level with Artificial Intelligence (AILS3)" dimension scored the highest (mean 4.96, SD 0.98), indicating that nursing students experience relatively positive feelings when interacting with AI. This finding aligns with the research results of Volpato et al [48]. In terms of EI, the "Emotional perception (EI1)" dimension had the lowest mean score 3.41 (SD 0.54), suggesting that nursing students have significant room for improvement in their ability to accurately identify and understand their own and others' emotions. This weakness may directly impact nursing students' empathetic communication and emotional regulation in high-pressure clinical settings, posing a potential risk to patient safety; failure to promptly identify patients' anxiety or distress may delay nursing decisions.

Emotion Perception: the Psychological Bridge Connecting the Emotional World and the AI World

The network structure constructed in this study showed that emotional perception (EI1), defined as the ability to recognize one's own and others' emotional states, was strongly connected to AILS and AS nodes. In this sample, emotional perception had the highest bridge strength, indicating that it was relatively well-connected to nodes in other communities. This pattern is consistent with Fu's [49] finding that emotional competence is associated with mental health and with deeper engagement with AI in educational contexts. The high bridge strength suggests that the ability to recognize emotions may be associated with trust in AI technology, which aligns with previous research showing that individuals with higher EI tend to monitor emotional cues and manage stress effectively [50]. Specifically, the positive connection between emotional perception and the assistance dimension (AILS1) indicated that students who reported greater awareness of their own confusion, anxiety, or sense of accomplishment during technology learning were also

XSL•FO
RenderX

more likely to view AI as a helpful tool [51]. This pattern is consistent with the observation by Mosleh et al [35]. that AI integration in teaching creates opportunities for emotional recognition and regulation, which may be easier for students with stronger emotional perception.

Emotional Application and Evaluation: the Engine Driving the Development of AS

The centrality measures showed that emotional use (EI4) and assessment (AS3) had the highest strength centrality, indicating that they were highly connected nodes within the network [52]. This pattern suggests that AS is associated not only with cognitive factors but also with emotional factors. Emotional use, defined as the ability to use emotional information for planning, creativity, and problem-solving, was positively connected with critical evaluation of AI outputs [13]. This finding is consistent with the observation that some individuals turn to GenAI for emotional guidance [50] and that emotional use may help nursing students engage in critical thinking when faced with complex AI outputs [53]. Evaluation ability, which concerns the judgment of AI-generated content [33], was closely connected with emotional use in the network. This pattern aligns with the finding by Deng and Chen [19] that AI-driven environments can support cognitive flexibility and independent judgment, possibly through emotional resilience. These exploratory observations invite further investigation using longitudinal or experimental designs to examine whether and how emotional use and evaluation skills might be related to AS [54].

AILS: a Potentially Important Bridging Node Between Emotion and AS

Network analysis results showed that EI, represented by emotional perception (EI1), had a positive connection with AILS, represented by assistance (AILS1) and comfort with AI (AILS3). For example, the edge weight between EI1 and AILS1 was 0.22. AILS also showed positive connections with AS, represented by usage (AS2) and evaluation (AS3). This pathway pattern, in which EI connected to AILS and AILS in turn connected to AS, is consistent with a mediating structure [55]. However, due to the cross-sectional design, this pattern should be interpreted as exploratory. It suggests that AILS may occupy a bridging position, but formal mediation analysis using longitudinal data would be required to test this hypothesis [49]. Prior research has shown that EI is associated with self-efficacy and with cognitive engagement with AI [49]. The connection pattern observed here is compatible with the idea that confidence in technical skills (AILS4) is associated with more frequent use of AI tools (AS2) [56]; that comfort with AI (AILS3) and anthropomorphic interaction (AILS2) are associated with lower anxiety and more exploration [25]; and that the belief that AI serves as an effective assistant (AILS1) is associated with reduced operational anxiety [53]. These observations are hypothesis-generating and require replication in independent samples with stronger designs. The significance of this approach for clinical practice lies in the fact that only by simultaneously strengthening both the emotional foundation and technical confidence can knowledge be translated into safe and effective clinical practice.

The Deep Mechanisms of AS Revealed by Negative Correlations

The most significant negative correlation was found between “Ethics (AS4)” and “Usage (AS2)” in the network. This indicates that at the current stage, nursing students who are more concerned about AI ethical issues (such as data privacy) may be more cautious in their use of AI tools, even exhibiting lower usage frequency [57]. Although this contradicts findings showing positive correlations between EI and reasons for adopting AI services or adoption/usage intentions [58], it reflects the development of critical thinking. When nursing students recognize the potential risks of technology, they may transition from blind tool users to critical thinkers, adopting more rational, selective use behaviors [59]. This finding resonates with the perspective of Ricon [60] that premature or excessive enthusiasm in medical AI may obscure ethical concerns, while measured caution is a prerequisite for responsible innovation. Participants in one study expressed concerns about potential privacy breaches and the risk of personal data theft [61]. Therefore, educators should not pursue unrestricted usage frequency but instead focus on cultivating students’ high-level application skills grounded in strong ethical vigilance.

Second is the negative correlation between “Emotional Intelligence in Others (EI3)” and “Anthropomorphic Interaction (AILS2).” This negative correlation may reflect multiple mechanisms. First, individuals with high EI are able to clearly distinguish the fundamental differences between human emotional connections and AI-simulated interactions. The ability to manage others’ emotions manifests as the capacity to perceive, influence, and regulate others’ emotions in interpersonal interactions, whereas the tendency toward anthropomorphic interaction is a psychological inclination to ascribe human characteristics to AI and interact with it in a social manner. Nursing students with high EI have a deeper understanding that, although AI can simulate empathetic responses, it lacks genuine emotional intent and reciprocity. Consequently, they consciously avoid viewing AI as an emotional substitute to prevent the development of inappropriate emotional dependence, which is consistent with Dakakni and Safa [62]. Second, cultural factors may play a role. In the context of Eastern culture, which emphasizes interpersonal harmony and emotional connection, nursing education places a high value on “authentic interpersonal interaction.” Nursing students with high EI may have internalized these professional values, leading them to adopt a more cautious or even resistant attitude toward anthropomorphizing AI. Third, from the perspective of clinical practice, this negative correlation carries positive ethical implications. The core of nursing practice lies in establishing trust within therapeutic interpersonal relationships. If nursing students are overly inclined to anthropomorphize AI and blur the boundaries between humans and machines, it may diminish their sensitivity to the emotional needs of real patients. Therefore, the lower tendency toward anthropomorphic interaction exhibited by nursing students with high EI can be viewed as an adaptive strategy for upholding the core values of the nursing profession [63].

System Integration Under the NUR.S.E.S. Framework: Synergistic Development of EI, AILS, and AS

The findings of this study provide empirical support for the NUR.S.E.S. framework, revealing the underlying psychological mechanisms behind its 6 dimensions. Specifically, emotional perception (EI1), as the strongest bridge node, empirically demonstrates the central role of E (EI) and S (social-emotional comfort) as the emotional cornerstones within the framework [64]; emotional application (EI4) and assessment (AS3), as core driving nodes, correspond to E and R (defect identification), respectively, indicating that emotional competence and technical critical thinking share an intrinsic synergistic mechanism; the various dimensions of AILS occupy key positions in the network that connect emotion and cognition, validating the theoretical premise within the framework that S (AILS) serves as the core driving force [65]. Ultimately, the synergy of all these elements achieves the framework's ultimate goal—S (shape the future)—that is, shaping the future [27].

In addition, this study provides an initial exploratory mapping of the interrelated factors associated with AS among nursing undergraduates, and these findings may offer insights for future research. From a practical perspective, nodes with high centrality, such as emotional use and evaluation, could exert influence on the overall network configuration through their connections with other nodes. Bridge nodes, such as emotional perception and comfort with AI, may transmit influences across different domains, making them potential targets for hypothesis-driven interventions. Accordingly, nursing educators might consider several tentative strategies, fostering students' emotional perception skills, which appear to link EI with AILS; creating low-anxiety AI learning environments to enhance comfort with AI; helping students set personalized learning goals and reflect on their emotional responses to strengthen emotional use and critical evaluation; and introducing case-based learning that combines clinical scenarios with AI outputs to ground technical critique and ethical decision-making in empathy for patients' emotional needs. Such a multidimensional approach, addressing emotional, cognitive, and skill components simultaneously, may support the development of nursing students as future professionals who can shape AI integration in nursing practice. However, all suggestions require empirical validation through longitudinal or experimental designs.

Research Significance, Limitations, and Future Directions

This study is the first to visualize, through network analysis, the patterns of association among EI, AILS, and AS in nursing students. It identified nodes that showed high centrality and bridging strength (emotional perception, emotional application, evaluation, comfort with AI). The observed association pattern suggests that emotional competence may be closely linked with technological confidence, which in turn may be linked with AS. These exploratory findings offer preliminary clues for future hypothesis-driven research. However, they do not establish causality, nor do they directly identify effective intervention targets. Any educational implications drawn from these results are speculative and require empirical validation [56].

This study has several limitations. First, the cross-sectional design cannot establish causal relationships between variables. Although the network pattern is consistent with some causal pathways, a reverse pathway (eg, higher AS leading to greater AILS) is equally plausible. Future research should use longitudinal or intervention designs to test dynamic relationships. Second, the sample originated from a single university, limiting generalizability. Cross-regional and cross-cultural comparisons are needed. Third, self-report scales may introduce bias; future studies could incorporate behavioral data and qualitative interviews.

Despite these limitations, this study offers profound theoretical insights and precise practical guidance for cultivating a new generation of nursing professionals who are "technically proficient, confident, and emotionally intelligent" in the era of AI. Future education and research should focus on developing integrated intervention programs that combine emotional education with technical training, empowering nursing students to embrace the challenges of the intelligent health care era fully.

Abstract

Background: Nursing students are the future workforce, and their readiness to use digital health tools is important. Previous studies have focused on knowledge and attitudes; however, they have not examined the wide range of digital health literacy levels that may influence nursing students' attitudes toward using telehealth in clinical settings.

Objective: This study aimed to determine the relationship between nursing students' digital health literacy and their attitudes toward telehealth use in practice.

Methods: A cross-sectional design was used. The sample consisted of undergraduate nursing students enrolled in a Bachelor of Nursing program at a selected Saudi Arabian university. The online survey used 2 scales: the Digital Health Care Literacy Scale and the Nurses' Attitudes Toward Use of a Telehealth Scale.

Results: A total of 273 students participated (mean age 21.3, SD 1.9 years). Most of the nursing students demonstrated a high digital health literacy level (n=184, 67.4%; mean Digital Health Care Literacy Scale score 11.9 out of 15, SD 3.1). Digital health literacy was a significant predictor of positive attitudes toward telehealth use in practice (adjusted odds ratio 1.48, 95% CI 1.28-1.71; *P*<.001). Male students were significantly less likely to report positive attitudes than female students (adjusted odds ratio 0.62, 95% CI 0.39-0.97; *P*=.03). However, academic year, telehealth workshops, and informatics courses were not significantly associated with positive attitudes toward telehealth use in practice.

Conclusions: Higher levels of literacy appear to correlate with more positive attitudes toward telehealth use in practice. However, current formal education and workshops had no apparent influence on digital health literacy. This suggests a potential need for strengthening digital training and development in nursing education. This may enhance telehealth readiness and support future digital health care delivery.

KEYWORDS

attitude; digital literacy; nursing education; nursing students; practice; telehealth; telemedicine

Introduction

The World Health Organization defines telehealth as the provision of health care services to individuals at a distance through information and communication technologies. It enables care to be delivered when the provider and the patient are in different physical locations [1]. Telehealth uses communication technologies for diagnosing and treating diseases, supporting research and assessment, and providing continuous professional education [1]. The rapid expansion of telehealth has transformed the health care system nationally and internationally. This expansion has increased the demand for professional competencies in digital health technologies.

Digital health literacy refers to the ability to access, analyze, and apply health information via electronic means to address health-related issues [2,3]. It also includes the ability to apply telehealth services and maintain electronic communication with health care professionals [2,3]. As telehealth becomes

XSL•FO
RenderX

increasingly integrated into health care systems, digital health literacy has become an important competency for nursing students and future health care professionals. Students with stronger digital competencies may engage more effectively with telehealth technologies and adapt more easily to digital health care environments [2,4].

Previous studies have reported moderate to high levels of digital health literacy among nursing students internationally. A study among Indonesian nursing students found that participants possessed fundamental digital health skills. These skills were influenced by factors including higher self-perceived internet skills and more frequent use of the internet for health-related purposes [5]. Similarly, a study from Turkey reported good digital health literacy among nursing students, with higher scores observed among older students and those who reported greater internet use [6]. In contrast, a study of nursing students in Ethiopia found that students had lower digital health literacy levels, particularly among first-year students and those from rural areas [7]. These findings suggest that digital health literacy may vary according to educational exposure, demographic factors, and access to digital technologies [5-7].

Studies conducted in Saudi Arabia have also revealed positive attitudes and moderate knowledge and awareness of telehealth among nursing students [8,9]. This highlights the need for educational programs that strengthen students' digital health competencies [9]. Similar findings were reported in Egypt, where nursing students show positive attitudes toward telehealth despite limited formal training [10,11]. In South Korea, nursing students also had limited direct exposure to telehealth education and clinical telehealth experiences [12]. Nevertheless, telehealth education and self-efficacy were associated with more positive attitudes toward telehealth use in practice [12].

Telehealth has undergone rapid expansion and transformation in Saudi Arabia. In alignment with Vision 2030, the Ministry of Health has launched the E-Health Initiative in Digital Transformation to improve the health care system's effectiveness and efficiency through information technology and digital transformation [13]. According to the Technology Acceptance Model, individual adoption of new technologies is influenced by perceived usefulness and ease of use [14,15]. In the context of telehealth, digital health literacy may contribute to these perceptions by improving individuals' confidence and ability to use digital technologies effectively [2-4].

Although previous studies have investigated nursing students' knowledge and attitudes regarding telehealth, digital health literacy and digital health knowledge are conceptually different and often used interchangeably. Digital health knowledge refers to an individual's understanding of what digital health is; when it is used; and the benefits, limitations, and associated ethical or legal considerations [1,16,17]. Digital health literacy, however, goes beyond awareness to encompass the practical ability to access, use, and assess telehealth services effectively in actual practice [2-4]. Whereas knowledge appears primarily cognitive and content-based, literacy is skill-based and reflects the capacity to apply that knowledge in real-world telehealth interactions [2,3]. Thus, a person may possess knowledge about telehealth without necessarily having the literacy required to use it competently.

Despite increasing integration of telehealth into health care education and practice, there is a lack of evidence regarding the relationship between nursing students' digital health literacy and their attitudes toward telehealth use in practice. Therefore, this study aimed to examine the relationship between digital health literacy and attitudes toward telehealth use in practice among undergraduate nursing students in Saudi Arabia. The study also explored demographic and educational factors associated with positive attitudes toward telehealth use in practice.

Methods

Design

A cross-sectional study was conducted to capture undergraduate nursing students' digital health literacy and attitudes toward telehealth use in practice at a single point in time. This study was reported according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement guidelines (Checklist 1).

Participants and Setting

This study focused on students enrolled in a Bachelor of Nursing program within a selected university in western Saudi Arabia. In this selected program, telehealth was introduced theoretically to nursing students in many courses; however, limited practical opportunities were available in clinical settings. A convenience sampling method was applied to recruit the participants, which included distribution of invites through social media platforms, emails, and announcements sent through the university's learning management system. To prevent duplicate responses, only 1 submission per device was allowed.

The inclusion criteria for the study were current nursing students in their second year to internship year. First-year students were excluded because they had not yet progressed into the specialized nursing curriculum and had limited exposure to clinical courses, nursing informatics, or telehealth-related learning experiences. Therefore, only second-year, third-year, fourth-year, and internship students were included to ensure that participants had sufficient academic and clinical exposure to meaningfully evaluate digital health literacy and attitudes toward telehealth use in practice. Licensed or registered nurses enrolled in bridging or postlicensure programs were excluded because prior professional experience may influence digital health literacy and attitudes toward telehealth use in practice independently of undergraduate nursing education.

The data were collected from November 2025 to January 2026. During this research period, 440 female and 223 male nursing students were enrolled in the Bachelor of Nursing program. The targeted sample size was 244, which met the required sample size, with a 95% CI and 5% margin of error.

Data Collection Instrument

The survey consisted of 3 sections: part 1 asked about demographic data, while the second and third parts used 2 scales adopted from previously published and publicly accessible

XSL•FO
RenderX

studies [18,19]. The first part of the survey collected demographic data such as sex, age, and academic year (second, third, fourth, or internship). Four questions inquired whether students had attended workshops or lectures related to telehealth, had taken nursing informatics courses, understood the definition of telehealth, and had applied telehealth in clinical placements.

The second part of the survey assessed digital health literacy using the Digital Health Care Literacy Scale (DHLS), with 3 items adopted from a previously published and publicly accessible study [18]. The scale exploratory factor analysis demonstrated good psychometric properties, with Cronbach α of 0.90 and 78% explained variance, supporting the scale's validity and reliability [18]. The responses were measured using a 5-point Likert scale ranging from strongly disagree to strongly agree.

The third part of the survey assessed the students' attitudes toward telehealth in practice using the 19-item Nurses' Attitudes Toward Use of a Telehealth Scale (NATUTS), which was obtained from a previously published and publicly accessible study [19]. NATUTS measured 3 factors: satisfaction, rejection, and development. The instrument demonstrated strong psychometric properties, with Cronbach α values ranging from 0.86 to 0.93 and a total explained variance of 64.4%, supporting its validity and reliability for assessing attitudes toward telehealth [19]. For descriptive interpretations purposes, the items were conceptually grouped under 4 domains, namely perceived benefits, professional integration and reliability, negative emotions and resistance, and engagement and self-development. Responses were recorded using a 5-point Likert scale ranging from strongly disagree to strongly agree.

The survey was administered in English because English is the language of nursing instruction at the study institution, and translation was therefore not needed. The survey was checked for face and content validity to assess its clarity and relevancy to the study objective before distribution. It was sent to 3 experts in nursing education and digital health for feedback. A pilot test was conducted with 10 nursing students to evaluate clarity, readability, and completion time. No modifications were required based on their feedback. Pilot participants were excluded from the final analysis.

The 3 DHLS items were adopted to assess the level of digital health literacy of the students. Each item was rated using the 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree). The 3 items were rated accordingly, and the total DHLS scores ranged from 3 to 15. The digital health literacy score was classified accordingly: 3 to 7 (low), 8 to 11 (moderate), and 12 to 15 (high). The total NATUTS score was calculated by adding up all 19 items after negatively worded items were reverse-coded to investigate predictors of positive attitudes toward telehealth. The total NATUTS scores ranged from 19 to 95. Higher scores indicated more positive attitudes toward telehealth use in practice. The sample mean score was used as a cutoff to dichotomize the overall attitude score. Mean score dichotomization has been used to facilitate interpretation of logistic regression outcomes when no established cutoff exists. Values below the mean were classified as negative attitudes, and scores equal to or above the mean were classified as positive attitudes. The multivariable logistic regression model was then fitted with the dichotomized variable.

Data Analysis

SPSS (version 28; IBM Corp) was used to perform all statistical analyses. Descriptive statistics were adopted to classify the nursing students' educational background, level of digital health literacy, sociodemographic attributes, and attitude toward telehealth use in practice. Frequencies and percentages denote the categorical variables, and means and SDs denote the continuous variables.

To examine factors associated with positive attitudes toward telehealth use in practice, multivariable logistic regression analysis was performed. Digital health literacy score, age, sex, academic year, exposure to telehealth education, completion of a nursing informatics course, and telehealth use during clinical placement were entered as independent variables in the model. Adjusted odds ratios (AORs) with 95% CIs were calculated. A *P* value of <.05 was considered statistically significant.

Ethical Considerations

The study adhered to ethical research standards and received approval by a relevant institutional review board of Umm Al-Qura University (receipt number HAPO-02-K-021-2025-5-2785). A statement at the beginning of the survey informed participants of the study's objectives, processes, possible benefits, and any related risks. It explained that participants' identities would remain anonymized and protected.

Participants provided consent by completing and submitting the survey anonymously. There were no significant risks, and the only cost to the participants was the time taken to complete the survey. Participation was voluntary, and responses were collected anonymously. No financial compensation or incentives were provided to participants for taking part in the study.

Results

Table 1 presents the sociodemographic and academic characteristics of the participating nursing students (N=273). Most students were aged 21 and 22 years (160/273, 58.6%), followed by 19 and 20 years (82/273, 30%), with a mean age of 21.3 (SD 1.9) years. Most participants were female (209/273, 76.6%). Regarding academic level, most students were in their third year (101/273, 37%), followed by fourth-year students (95/273, 34.8%), nursing interns (45/273, 16.5%), and second-year students (32/273, 11.7%). A high proportion of students reported having attended a telehealth workshop or lecture (198/273, 72.5%) and completing a nursing informatics course (194/273, 71.1%). The vast majority reported knowing the meaning of telehealth (244/273, 89.4%), and more than half reported using telehealth during their clinical placement (148/273, 54.2%).

>23	31 (11.4)
Age (years), mean (SD)	21.3 (1.9)
Sex, n (%)	
Male	64 (23.4)
Female	209 (76.6)
Academic year, n (%)	
Second year	32 (11.7)
Third year	101 (37)
Fourth year	95 (34.8)
Nursing intern	45 (16.5)
Have you attended a workshop or lecture about telehealth?, n (%)	
Yes	198 (72.5)
No	75 (27.5)
Have you taken a nursing informatics course?, n (%)	
Yes	194 (71.1)
No	79 (28.9)
Do you know the meaning of telehealth?, n (%)	
Yes	244 (89.4)
No	29 (10.6)
During your clinical placement, do you use telehealth?, n (%)	
Yes	148 (54.2)
No	125 (45.8)

Table 2 illustrates the distribution of nursing students' responses to the 3-item DHLS. More than half (140/273, 51.3%) strongly agreed that they could use applications or programs such as Zoom independently, while 77 (N=273, 28.2%) agreed. Similarly, 130 (N=273, 47.6%) students strongly agreed and 75 (27.5%) agreed that they could set up video chats without assistance. Regarding problem-solving skills, 91 (N=273, 33.3%) students agreed and 80 (29.3%) strongly agreed that they could resolve basic technical issues on their own, while a smaller proportion (65/273, 23.8%) remained neutral. The overall DHLS score ranged from 3 to 15, with a mean of 11.9 (SD 3.1) out of 15.

XSL•FO
RenderX

Table . Distribution of nursing students' responses to the Digital Health Care Literacy Scale items (N=273).

Digital Health Care Literacy Scale items[a]	Strongly disagree, n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Strongly agree, n (%)
I can use applications or programs (such as Zoom) on my cell phone, computer, or another electronic device on my own (without asking for help from someone else).	16 (5.9)	13 (4.8)	27 (9.9)	77 (28.2)	140 (51.3)
I can set up a video chat using my cell phone, computer, or another electronic device on my own (without asking for help from someone else).	15 (5.5)	20 (7.3)	33 (12.1)	75 (27.5)	130 (47.6)
I can solve or figure out how to solve basic technical issues on my own (without asking for help from someone else).	12 (4.4)	25 (9.2)	65 (23.8)	91 (33.3)	80 (29.3)

[a]Range 3-15; mean 11.9, SD 3.1.

The overall distribution of nursing students' digital health literacy levels. Most participants had a high level of digital health literacy (184/273, 67.4%). Exactly 61 (22.3%) students had a moderate level, and a smaller proportion of students (28/273, 10.3%) showed a poor level of digital health literacy.

Table 3 presents the distribution of nursing students' attitudes toward telehealth use in practice. Overall, the findings show a predominantly positive attitude. In the perceived benefits of telehealth domain, most agreed or strongly agreed that telehealth reduces nurses' workload (211/273, 77.3%), is an important part of nursing services (218/273, 79.9%), is essential in nursing (204/273, 74.7%), improves individuals' quality of life (232/273, 85%), simplifies patient-nurse communication (210/273, 76.9%), enables nursing services to be carried out more effectively (209/273, 76.6%), gives professional advantage (202/273, 74%), and eases nurses' workloads (221/273, 80.9%). In the professional integration and reliability domain, 216 (N=273, 79.1%) students agreed or strongly agreed that they would like to include telehealth in professional practice, 173 (63.3%) considered it reliable, and 209 (76.5%) viewed it as essential in nursing services. In the negative emotions and resistance domain, agreement was much lower, indicating limited reluctance: only 61 (22.4%) reported disliking telehealth, 69 (25.3%) felt nervous using it, 67 (24.5%) experienced conflict with its use, 100 (36.7%) used it because they had to, and 71 (26%) would not recommend it to colleagues. Regarding the engagement and self-development domain, over half agreed or strongly agreed that they follow current telehealth developments (135/273, 49.5%), improve themselves regarding telehealth (167/273, 61.2%), and research telehealth (129/273, 47.3%). The overall NATUTS score ranged from 19 to 95, with a mean of 70.93 (SD 11.52) out of 95.

XSL•FO

I follow current developments regarding telehealth.	49 (17.9)	89 (32.6)	135 (49.5)
I research telehealth.	57 (20.9)	87 (31.9)	129 (47.3)
I improve myself regarding telehealth.	32 (11.7)	74 (27.1)	167 (61.2)

[a]Mean 70.93, SD 11.52; range 19-95.

Multivariable logistic regression analysis was conducted to determine whether digital health literacy predicted positive attitudes toward telehealth use in practice after controlling for demographic and educational variables. Digital health literacy was a significant predictor of positive attitudes toward telehealth use in practice (AOR 1.48, 95% CI 1.28-1.71; *P*<.001). Male students were significantly less likely to report positive attitudes compared with female students (AOR 0.62, 95% CI 0.39-0.97; *P*=.03). No significant associations were observed for age, academic year, telehealth workshops, informatics courses, or telehealth use during clinical placement (Table 4).

[b]Significance level: $P<.05$.

Discussion

Principal Findings

The purpose of this study was to examine the relationship between digital health literacy and attitudes toward telehealth use in practice among nursing students. The findings demonstrated that high digital health literacy was significantly associated with positive attitudes toward telehealth use in practice. Students with higher digital health literacy were significantly more likely to perceive telehealth as beneficial, reliable, and relevant for nursing practice.

Most of the nursing students demonstrated a high level of digital health literacy. This result aligns with previous studies that found moderate to high digital health literacy among nursing and health sciences students [20,21]. However, the findings should be interpreted with caution. Although students may possess the ability to access and use digital health information, this does not necessarily indicate preparedness to apply telehealth in complex clinical situations. Previous studies have shown that nursing students often experience difficulties in critically evaluating online health information and in applying digital knowledge in clinical decision-making [20,21]. Thus, possessing digital health literacy skills alone may be insufficient without practical telehealth training and supervised clinical application.

Most of the students stated that telehealth decreases workload, improves the quality of life of patients, and plays a critical role in nursing practice. These results are consistent with those of previous studies demonstrating that nursing students perceive telehealth as beneficial to health care accessibility, efficacy, and communication [19,22]. Positive attitudes toward telehealth use in practice may reflect nursing students' increasing exposure to digital technologies in both educational and health care settings. These attitudes may also be influenced by the rapid expansion of telehealth services following the COVID-19 pandemic [6,20]. Thus, students may perceive telehealth as consistent with contemporary nursing roles which require digital communication and remote patient monitoring [4,22].

Despite the reported positive attitudes, some students exhibited negative feelings such as reluctance and nervousness. These findings are important because they show that positive attitudes can sometimes coexist with discomfort, limited confidence, or perceived external pressure to use digital technologies. This may indicate that some students accept telehealth while still lacking confidence in their practical ability to use it efficiently and effectively. Such findings align with those of previous research, where the nursing students were hesitant due to reliability concerns and insufficient practical exposure [12,23]. These findings suggest that telehealth education should include hands-on simulation and supervised practice experiences to improve confidence and reduce resistance.

The presence of negative emotions toward telehealth use in practice may reflect limitations of current nursing education strategies. Although many students attended telehealth workshops or completed informatics-related courses, these experiences did not lead to more positive attitudes toward telehealth use in practice. This finding suggests that current educational strategies may emphasize theoretical knowledge more than practical competency. Short workshops or isolated informatics courses may increase awareness of telehealth without sufficiently improving students' confidence, communication skills, or ability to integrate telehealth into patient care [23]. Subsequently, students may recognize the importance of telehealth while experiencing anxiety or resistance to its practical implementation.

Digital health literacy independently predicted students' attitudes toward telehealth use in practice even after controlling for demographic and educational variables. This finding suggests that digital health literacy is not only a technical skill but also a determinant of technology acceptance in health care settings.

XSL•FO
RenderX

Students who are confident in using digital tools may perceive telehealth systems as easier to use and thus more useful in clinical care. These results align with the Technology Acceptance Model, which suggests that individuals with higher perceived competence in technology are more likely to adopt digital innovations in practice [14,15]. However, students with lower literacy levels may experience uncertainty and resistance due to difficulties navigating digital health care environments. These findings suggest that digital competencies play a critical role in shaping students' readiness to adopt telehealth technologies in future clinical practice. As telehealth becomes increasingly integrated into health care systems globally, digital health literacy may represent an essential professional competency for future nurses [4]. Therefore, improving digital health literacy may help not only to develop technical competence but also to reduce anxiety and strengthen professional acceptance of telehealth technologies.

The study statistically found that male students were less likely to report positive attitudes toward telehealth use in practice than female students. Although evidence regarding sex differences in attitudes toward telehealth among nursing students remains limited, this result may be related to communication preferences, engagement with patient-centered care, or attitudes toward health care technologies. However, this result should be interpreted cautiously given the lack of literature available and the potential influence of cultural and educational factors. Additional research is needed to better understand the reasons underlying these differences.

Overall, the results imply that telehealth education in nursing programs needs to be further enhanced beyond theoretical instruction. While students generally demonstrated positive attitudes and high digital health literacy, the persistence of nervousness, reluctance, and feelings of obligation indicates gaps between knowledge and practical readiness. Nursing curricula may benefit from integrating experiential telehealth learning activities such as simulations, virtual consultations, case-based learning, and supervised clinical telehealth experiences. These approaches may help students develop greater confidence, reduce resistance, and improve their ability to apply telehealth competently in real health care settings.

To summarize, digital health knowledge reflects understanding, whereas digital health literacy reflects the capacity to apply that understanding in practice. This study contributes to existing evidence that digital health literacy plays an important role in technical competence and is positively associated with students' attitudes toward telehealth use in practice. Nursing education courses need to strengthen digital competencies to reduce resistance and promote more positive perceptions of telehealth within nursing. As telehealth becomes integrated into health care systems worldwide, preparing digitally competent nursing graduates is critical to future workforce readiness.

Limitations

The cross-sectional design and single-educational setting of this study make it difficult to draw conclusions about the causal relationships between students' attitudes toward telehealth use in practice and their level of digital health literacy. It was not possible to ascertain whether exposure to telehealth education results in long-lasting changes in attitudes or abilities because the data were gathered all at once. Additionally, the results are less applicable to other nursing programs with distinct curricula, resources, or student characteristics when the study is limited to a single institution. Consequently, findings should be interpreted cautiously, as they might not be generalizable to the broader population of undergraduate nursing students because of potential self-reported bias.

Conclusions

The findings of this study demonstrate that nursing students have high levels of digital health literacy. In addition, most of the students exhibit positive attitudes toward telehealth use in practice, particularly pertaining to patient care delivery, decreasing workload, and professional integration. The significant finding was the association between higher digital health literacy levels and positive attitudes toward telehealth use in practice. These findings suggest a potential need to strengthen digital health content within nursing curricula to strengthen nurses' digital skills through formal training and continuous professional development.

Educators and clinical leaders can modify training strategies to meet the needs of specific groups. This targeted approach may reduce disparities in digital health and telehealth competencies across the clinical workforce. Offering workshops or informal learning experiences does not guarantee improved competency, so such clinical training should include skills that support telehealth use. Integrating structured, evidence-based digital health literacy curricula into clinical training may ensure that future health care providers develop their competency as technologies evolve.

Acknowledgments

The authors would like to acknowledge the students who provided their time to participate in this research. The authors used generative artificial intelligence (ChatGPT, OpenAI) to assist with language editing and improving the clarity and readability of the manuscript. The final manuscript preparation were performed by the authors, who take full responsibility for the accuracy and integrity of the work.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Abstract

Background: The rapid advancement of digital technologies, combined with the evolving complexity of health care environments, has introduced a new paradigm in nursing practice. Clinical nurses are now required not only to deliver safe and effective patient care but also to demonstrate competencies in digital literacy and innovation. Among these emerging competencies, digital leadership has become a critical attribute—enabling nurses to lead digital transformation, ensure patient safety, enhance care quality, and support system-level change within health care organizations. Despite its increasing relevance, there is a notable absence of validated measurement tools tailored to assess digital leadership in clinical practice.

Objective: This study aimed to develop and psychometrically validate a Digital Leadership Scale for Clinical Nurses (DLS-CN) to systematically evaluate the digital leadership capabilities of nurses working in clinical settings.

Methods: The scale development process followed a rigorous multistep procedure. Initial items were derived from previous qualitative research involving a literature review and in-depth interviews, complemented by an additional literature review conducted in this study. The content validity of 38 preliminary items was evaluated by 9 experts over 2 rounds. A pilot test was conducted with 30 nurses, followed by cognitive interviews with 5 nurses to refine item clarity and relevance. The final set of items was administered to 446 clinical nurses across various health care institutions. Data were randomly split for exploratory factor analysis and confirmatory factor analysis. Additional analyses were conducted to evaluate item discrimination, convergent validity, and internal consistency using IBM SPSS 25.0 and AMOS 23.0.

Results: The finalized DLS-CN consists of 29 items grouped under four domains: (1) ability to use digital technology, (2) digital safety management, (3) digital collaboration mindset, and (4) organizational influence. These 4 factors explained 56.9% of the total variance. The scale showed strong internal consistency (Cronbach α=0.95). Convergent validity was demonstrated through strong positive correlations with the Nursing Informatics Competency Scale (Pearson correlation coefficient r=0.82; P<.001) and the Self-Leadership Scale (Pearson correlation coefficient r=0.83; P<.001).

Conclusions: The DLS-CN is a valid and reliable instrument for measuring digital leadership among clinical nurses. It offers a practical tool for educators, administrators, and researchers to assess and enhance digital leadership capabilities—ultimately supporting the digital transformation of health care systems.

Introduction

The digital transformation era has accelerated the adoption of digital technologies in the health care sector, particularly after COVID-19, which catalyzed the integration of such technologies into clinical practice [1-3]. Clinical nurses are increasingly using digital tools to ensure safe care environments and to provide evidence-based nursing [4,5]. Common technologies used by nurses include wearable devices, electronic health records, and Barcode Medication Administration systems [6,7], all of which enhance patient safety and efficiency. The adoption of these digital tools in clinical settings has been shown to improve nursing efficiency and patient outcomes [8].

As health care environments become increasingly digitalized, nurses are expected not only to use digital technologies in practice but also to adapt to and support digital change in clinical settings. Nurses serve as coordinators, ensuring effective communication among patients, families, health care

XSL•FO
RenderX

professionals, and nursing peers, which is directly related to patient safety [4,9]. In this context, digital leadership encompasses not only the technical ability to understand and apply digital tools [10] but also the capacity to introduce new communication systems and foster collaboration among team members [11]. Therefore, to successfully implement digitalization and health information technologies within hospital organizations, leadership from nurses who continuously enhance and manage their clinical competencies is essential [12,13]. The level of leadership demonstrated by nurses is closely linked to the quality of nursing services [14].

Digital leadership combines traditional nursing competencies with digital capabilities, thereby improving the quality and efficiency of care delivery [8]. In rapidly evolving health care environments, digital leadership is no longer a personal attribute of individual nurses but a comprehensive competency influencing teams and organizations [15]. Nurses must demonstrate adaptability to digital changes [2], solve problems arising during digital transitions [11,16], and support peer education and motivation [2,17]. Effective digital leadership also includes ethical considerations, such as the protection of patient information in the context of big data usage [18]. Existing tools for measuring digital leadership have primarily been developed for managers or employees in general corporate settings, focusing on behaviors and skills required in digital work environments, including vision sharing and resource support. These tools aim to assess general leadership attributes applicable in digital contexts [19,20]. However, they are limited in that they do not reflect the specific characteristics of nursing practice, which involves unique therapeutic relationships between nurses and patients [21], nor do they account for the evolving nature of contemporary clinical settings due to the introduction of new digital technologies [3]. While digital leadership among nurses—encompassing the ability to adapt to digital transformation and effectively integrate digital technologies with health data—is increasingly essential [2,22,23], there remains a lack of measurement tools that are specifically developed to reflect the unique roles and characteristics of clinical nurses.

The purpose of this study is to develop and validate the Digital Leadership Scale for Clinical Nurses (DLS-CN). This scale is intended to accurately assess the level of digital leadership among clinical nurses and provide a foundation for evaluating and enhancing their leadership capabilities in digital health care environments.

Methods

Study Design

This study is a quantitative methodological research conducted to develop and evaluate a measurement tool for assessing digital leadership among clinical nurses. The development of the DLS-CN was carried out in 2 phases, based on the tool development process proposed by DeVellis and Thorpe [24]. In the first phase, preliminary items were developed, followed by content validity testing, cognitive interviews, and a pilot survey. In the second phase, the tool was administered to clinical nurses to examine its reliability and validity.

Scale Development Process

Phase 1: Preliminary Item Development

Clarification of the Conceptual Definition

This study was based on the hybrid model of Schwartz-Barcott and Kim [25], applying theoretical, fieldwork, and final analytic phases. Based on a previous study analyzing the concept of digital leadership [15], a literature review was conducted, and concept attributes were integrated to establish a conceptual framework and identify core attributes. Through this process, 6 components of digital leadership were identified: digital problem-solving ability, digital ethical sensitivity, digital mindset, self-growth, digital collaboration, and organizational influence.

Item Generation

A total of 104 initial items were generated across 6 components of digital leadership for clinical nurses. Specifically, 21 items measured digital problem-solving ability, 19 items measured digital ethical sensitivity, 16 items measured digital mindset, 9 items measured self-growth, 17 items measured digital collaboration, and 22 items measured organizational influence.

Selection of Measurement Format

Since the items were designed to measure the level of agreement with statements regarding digital leadership among clinical nurses, the widely used Likert scale was deemed appropriate [24]. Therefore, a 5-point Likert scale was selected.

Expert Content Validity Assessment

To evaluate the content validity of the preliminary items, an expert panel of 9 members was formed: 2 clinical nurses with more than 5 years of experience; 2 nurse unit managers; 2 nursing professors; and 1 expert each in digital health care, leadership, and hospital management. After the researchers explained the concept of digital leadership for clinical nurses, the experts rated the appropriateness of the item content and components using a 4-point Likert scale. For item-level evaluation, the item-level content validity index was considered acceptable if it was 0.78 or higher. To assess overall content validity, the scale-level content validity index was calculated by averaging, with 0.90 or higher judged as acceptable [26]. Two rounds of expert validation were conducted. As a result of the first round, 71 items were selected. After the second round, the number was reduced to 46 items. During this process, sentence order and expressions were revised for better clarity and specificity, especially when abstract or ambiguous wording was identified.

Cognitive Interviews

Cognitive interviews were conducted with 5 clinical nurses who met the inclusion criteria of the main study. Each interview lasted 30 to 40 minutes and aimed to understand how participants interpreted and responded to the preliminary items. During the interviews, participants were asked to explain their thought processes while answering each item, including how they understood the wording, whether any terms were unclear, and whether the items were easy or difficult to answer. The interview data were analyzed by reviewing participants' explanations and feedback on item comprehension, wording,

XSL•FO
RenderX

and response processes. Based on these findings, items were revised to improve clarity and reduce potential response errors. When similar or overlapping content was identified, the researchers rechecked whether the same concern was expressed by other interviewees before making revisions. The revised items were then reviewed again with the interviewees to confirm their appropriateness. Some participants questioned the appropriateness of the term "hospital information system," but after reviewing related tools, literature, and expert texts, the term was retained to encompass systems such as electronic medical records and order communication systems. Regarding terms describing digital collaboration tools or systems, alternatives like "intranet" and "groupware" were suggested; however, "digital collaboration system" was found to be the most understandable and suitable. In response to feedback, the term "real-time" was added to better reflect the advantages of system usage. While some general staff nurses noted difficulty adopting new technologies and resources, replacing terms like "utilize" or "apply" was found to weaken alignment with intended attributes, so the original expressions were maintained. After revising the items, the modified 46 items were confirmed for appropriateness through follow-up review with the interviewees.

Pilot Study

To identify issues with the preliminary items, a pilot study was conducted with 30 clinical nurses who met the same criteria as those in the main study. This was conducted via an online survey identical in format to the main study. Respondents rated item comprehensibility on a 5-point scale (1="very difficult" to 5="very easy"), yielding an overall average of 4.14 (SD 0.24), indicating that the items were well understood. The time required to complete the survey ranged from 5 to 25 minutes, with an average of 11 (SD 1.84) minutes. Open-ended questions confirmed that item length, font size, and type were appropriate. Based on the pilot results, items with duplicate meanings or unclear wording were revised. Additionally, a new item was added to the organizational influence component, "I can help organizational members experiencing difficulties in digitalized work environments," to complement the existing item, "I can ask organizational members for help when I face difficulties." All items were revised through linguistic review to ensure correct spacing, terminology, and order. Ultimately, the preliminary item pool was finalized with 47 items across 6 components.

Phase 2: Instrument Evaluation—Reliability and Validity Testing

Participants

Participants were 446 clinical nurses working at tertiary or general hospitals in South Korea. Eligible participants were nurses who were directly involved in patient care and had at least 1 year of clinical experience. Nurses with less than 1 year of experience were excluded because they were considered to be in the novice stage of acquiring the knowledge and skills necessary for nursing practice [27,28]. Nurses in administrative, educational, or nondirect care roles were also excluded. A minimum sample size of 200 is generally recommended for factor analysis, and for confirmatory factor analysis (CFA), a commonly used rule of thumb is that the sample should be at least 10 times the number of estimated parameters [29,30]. Therefore, the total sample size of 446 was considered adequate. To examine the factor structure and cross-validate the model, the total sample was randomly divided into 2 equal groups, with 223 participants assigned to exploratory factor analysis (EFA) and 223 to CFA. This equal split was used to ensure independent and sufficiently large samples for both analyses.

Instruments

To evaluate convergent validity, 2 instruments were selected: the Nursing Informatics Competency Scale [31] and the Self-Leadership Scale [32]. The Nursing Informatics Competency Scale includes 20 items across 5 components: "Basic information and communication technology use" (3 items), "Utilization of nursing information" (5 items), "Professional responsibility and ethics" (5 items), "Use of information and communication technology in nursing" (4 items), and "Attitudes toward nursing informatics" (3 items). Each item is rated on a 4-point Likert scale. The reliability of the original scale was a Cronbach α of 0.91 [31], and in this study, internal consistency reliability was assessed using Cronbach α based on the responses of the study participants, with a Cronbach α coefficient of 0.91, indicating excellent internal consistency. The Self-Leadership Scale consists of 16 items across 4 components: "Collaborative self-dialog strategies" (4 items), "Physical vitality enhancement strategies" (4 items), "Goal-oriented self-training strategies" (4 items), and "Self-respect pursuit strategies" (4 items). This instrument uses a 5-point Likert scale. The original reliability was a Cronbach α of 0.86 [32], and in this study, the Cronbach α was also calculated using the current dataset, yielding a coefficient of 0.91, which indicated excellent internal consistency.

Data Collection

Data were collected from March 10, 2024, to March 30, 2024, through a self-administered online survey using a nonprobability convenience sampling method. Participants were able to complete the survey at their preferred time and location without direct contact with the researchers. To recruit nurses from diverse regions, recruitment notices containing the contact information of the researchers and the survey link (URL) or QR code were posted on online nursing community boards and workplace forums, allowing eligible participants to voluntarily access and complete the survey. All items were set as mandatory, preventing participants from proceeding without responding; consequently, no missing data were observed in the submitted questionnaires. Data collection continued until the predetermined sample size required for item analysis was reached, after which the survey was closed to prevent additional responses. Because the survey link was distributed through open online communities and workplace forums, the total number of individuals who viewed the recruitment notice could not be determined, and thus the response rate could not be calculated.

Data Analysis

Collected data were analyzed using IBM SPSS Statistics version 25.0 and AMOS version 23.0. First, participants' general characteristics were analyzed using frequencies, percentages,

XSL•FO
RenderX

means, and SDs. Second, for the item analysis, means, SDs, skewness, kurtosis, inter-item correlations, item-total correlations, and reliability (if an item was deleted) were calculated. Third, to test the suitability of EFA, the Kaiser-Meyer-Olkin (KMO) measure and the Bartlett test of sphericity were used. Fourth, principal component analysis with varimax rotation was performed to extract factors. Fifth, CFA was conducted to evaluate model fit and test convergent and discriminant validity. Sixth, convergent validity was also examined using the Pearson correlation coefficient. Finally, internal consistency reliability was tested using Cronbach α.

Ethical Considerations

This study was approved by the Institutional Review Board of Daegu Catholic Medical Center (CR-23-148). The online survey introduction clearly explained the study's purpose, informed consent, procedures, voluntary participation, confidentiality, potential benefits and risks, and stated that the data would be used only for research purposes. Participants received a small token of appreciation for their involvement. The study was conducted in accordance with the ethical principles of the Declaration of Helsinki.

Results

General Characteristics of Participants

A total of 446 clinical nurses participated in the survey (Table 1). Among them, 223 participants were included in the EFA, with an average age of 30.71 (SD 5.45) years. Most participants were female (208, 93.3%). Regarding the type of hospital where they worked, 137 participants (61.4%) were employed at tertiary hospitals and 86 (38.6%) at general hospitals. The most common region was Seoul, the capital, with 106 participants (47.5%). The average length of clinical experience was 70.41 (SD 46.68) months. In terms of work departments, 137 participants (61.4%) worked in general wards, 52 (23.3%) in special units (eg, intensive care units, operating rooms, emergency rooms), 17 (7.6%) in outpatient clinics, and 17 (7.6%) in other departments. For the CFA, 223 participants were included, with an average age of 31.07 (SD 4.81) years. The majority were female participants (200, 89.7%). A total of 131 participants (58.7%) worked in tertiary hospitals and 92 (41.3%) in general hospitals. The highest number of participants was also from Seoul (99, 44.4%). The average length of clinical experience was 74.31 (SD 57) months. Regarding work departments, 147 participants (65.9%) worked in general wards, 38 (17.0%) in special units, 25 (11.2%) in outpatient clinics, and 13 (5.8%) in other departments.

[f]OPD: outpatient department.

Item Analysis

To examine the distribution of items in the 223 collected responses for factor analysis, the mean, SD, skewness, and kurtosis were calculated for each item. Since none of the items had an absolute skewness value greater than 3.0 or an absolute kurtosis value greater than 8.0, all items met the assumption of normality [33]. Item-total correlation coefficients were reviewed, and items with coefficients below 0.30 or above 0.80 were removed, as these values suggest low contribution to the scale or item redundancy [34]. Seventeen items were removed due to low internal consistency reliability and weak correlation between item pairs. Based on corrected item-total correlation and changes in reliability after item deletion [33], the corrected item-total correlations ranged from 0.43 to 0.72, and the reliability did not significantly change upon item deletion (Table 2). As a result, 30 items were retained for further analysis.

Exploratory Factor Analysis

EFA using principal component analysis with varimax rotation was conducted on the 30 items of the DLS-CN. Prior to the factor analysis, data adequacy was assessed using the KMO measure and the Bartlett test of sphericity. The KMO value was 0.96, indicating excellent sampling adequacy, and the Bartlett test of sphericity was statistically significant [35], confirming the data's suitability for factor analysis. To determine the number of factors, eigenvalues greater than 1.0 and a cumulative variance explanation rate exceeding 60% were used based on Kaiser rule. Scree plot analysis and the interpretability of the factor structure were also considered. Items were retained based on communalities greater than 0.40, factor loadings above 0.40, and at least 3 items per factor [36]. One item with a factor loading below 0.40 was removed. The final analysis included 29 items, with a KMO of 0.95 and a statistically significant Bartlett test (χ^2_{820}=4799.3; *P*<.001), indicating the appropriateness of factor analysis. The EFA extracted 4 factors with eigenvalues greater than 1.0, explaining a cumulative variance of 56.9%. Communality values ranged from 0.52 to 0.64, and all factor loadings exceeded 0.40, indicating good model fit. The purpose of factor analysis is to understand the pattern of data and clarify the interpretability of factors [37]. The factor loadings and item contents were examined to ensure conceptual coherence. Cross-loading items that were theoretically essential were assigned to conceptually valid factors. The inter-item correlation coefficients within subfactors were as follows: factor 1: 0.43 to 0.64; factor 2: 0.35 to 0.57; factor 3: 0.35 to 0.51; and factor 4: 0.39 to 0.052, indicating that the model estimation was appropriate (Table 3).

Confirmatory Factor Analysis

CFA was conducted to verify whether the 4 factors and 29 items extracted during the EFA appropriately reflected the constructs of digital leadership among clinical nurses. The model's goodness-of-fit was assessed to confirm the adequacy of the structure. To evaluate the model fit, the chi-square statistic was examined. A model was considered acceptable if the normed chi-square χ^2/df was less than 3, the comparative fit index was above 0.90, the root mean square error of approximation was below 0.06, and the standardized root mean squared residual was below 0.80 [38]. The results of the CFA indicated that the chi-square value was statistically significant, and the normed chi-square χ^2/df was 1.8, satisfying the criterion of being below 3. The comparative fit index was 0.91, exceeding the threshold of 0.90. The root mean square error of approximation was 0.06, which meets the criterion for a good model fit. The standardized root mean squared residual was 0.05, which is below the acceptable cutoff of 0.08, indicating that the model had a generally good fit (Table 2).

To verify the convergent validity of each factor, the standardized factor loading was required to be 0.5 or higher, the significance of the unstandardized regression coefficient (critical ratio) was required to exceed 1.97 (P<.05), the construct reliability had to be 0.7 or higher, and the average variance extracted (AVE) needed to be 0.5 or higher [39]. The results of the convergent validity test showed that the critical ratio values of the unstandardized regression coefficients ranged from 7.83 to 10.63, significantly exceeding the threshold [30], confirming that the measured items met the conditions necessary for validity testing. The standardized factor loadings for all factors met the criterion of 0.5 or higher. The AVE values for each factor ranged from 0.52 to 0.57, satisfying the minimum requirement of 0.50. The construct reliability values ranged from 0.85 to 0.90, all exceeding the minimum requirement of 0.70. Therefore, the DLS-CN demonstrated adequate convergent validity in terms of item construction. Through this, it was confirmed that 4 factors consistently measured the construct of "Digital Leadership Scale for Clinical Nurses," and that the 29 items consistently represented the corresponding factors. To assess discriminant validity, interconstruct correlation matrices were examined (Table 4). Discriminant validity was evaluated by checking whether the AVE of each factor was greater than the squared correlation coefficients between the factors [39]. In some cases, such as the ability to use digital technology–digital collaboration mindset, ability to use digital technology–organizational influence, digital safety management–digital collaboration mindset, and digital collaboration mindset–organizational influence, the squared correlations between factors exceeded the AVE of the individual constructs, indicating that discriminant validity was only partially satisfied.

Table . Correlations between variables and verification of construct validity (n=223).

Variables	Squared correlation (P value)				AVE[e]	CR[f]
	F1[a]	F2[b]	F3[c]	F4[d]		
F1	1	—[g]	—	—	0.57	0.91
F2	0.49 (<.001)	1	—	—	0.54	0.85
F3	0.66 (<.001)	0.53 (<.001)	1	—	0.52	0.90
F4	0.71 (<.001)	0.51 (<.001)	0.68 (<.001)	1	0.52	0.90

[a]F1: ability to use digital technology.

[b]F2: digital safety management.

[c]F3: digital collaboration mindset.

[d]F4: organizational influence.

[e]AVE: average variance extracted.

[f]CR: construct reliability.

[g]Not applicable.

Convergent Validity Testing

To verify convergent validity, the correlations with the Nursing Informatics Competency Measurement Tool [31] and the Self-Leadership Scale [32] were examined. The correlation with the Nursing Informatics Competency Scale was 0.82 (P<.001), and the correlation with the Self-Leadership Scale was 0.83 (P<.001). Since the correlation coefficients were all above 0.70, convergent validity was confirmed.

Reliability Testing

Reliability was tested using Cronbach α, with a criterion of 0.70 or higher [29,40]. Cronbach α for the 29 items measuring DLS-CN was 0.95.

By subfactor, Cronbach α was as follows: factor 1 (ability to use digital technology): 0.88; factor 2 (digital safety management): 0.78; factor 3 (digital collaboration mindset): 0.86; and factor 4 (organizational influence): 0.87.

Since Cronbach α for all subfactors and the overall tool exceeded 0.70, reliability was confirmed.

Final Items

In this study, the final version of the DLS-CN consisted of 29 items across 4 factors (Table 5).

By subfactor, the items were as follows: 8 items for the ability to use digital technology, 5 items for digital safety management,

XSL•FO
RenderX

8 items for a digital collaboration mindset, and 8 items for organizational influence.

Table . Final items of the convergence of Digital Leadership Scale for Clinical Nurses.

Factors and items	Item number
Ability to use digital technology	
I can provide patient-centered care by using digital technology.	1
I can explore ways to improve digital systems and processes for patient care and treatment.	46
I can explain the importance of actively using digital technology.	39
I can actively use new information obtained through digital technology to solve patients' health problems.	8
I can present new information obtained through digital technology to address issues in the nursing work environment.	9
I can systematically collect data on patients' health status and nursing needs using digital technology.	2
I can argue for the necessity of applicable resources (human, systems, equipment, etc) in the digitalizing clinical environment.	45
I understand the principles of digital technology necessary for nursing tasks and can apply them to patients.	4
Digital safety management	
I can learn methods for using and managing new digital technologies applicable to patient care.	22
I can maintain a secure environment for protecting patient privacy in the digitalizing clinical setting (eg, logging out of computers when changing locations).	14
I perform nursing tasks in accordance with organizational guidelines and procedures for managing personal information in the digital clinical environment.	16
I believe self-development is important for improving digital knowledge and technical skills related to nursing tasks.	26
I can request help from organizational members when encountering difficulties in the digital clinical environment.	30
Digital collaboration mindset	
I can assist organizational members who are struggling in the digital clinical environment.	31
I can logically express my opinions so that organizational members can understand them using digital collaboration systems (eg, EMR[a], PACS[b], in-hospital messenger, etc).	33
I feel comfortable exchanging real-time opinions through digital collaboration systems (eg, EMR, PACS, in-hospital messenger, etc).	37
I can understand organizational members' opinions easily when communicating via digital collaboration systems (eg, EMR, PACS, in-hospital messenger, etc).	34
I am not afraid of adapting to digital changes in the clinical setting.	20
If I do not know how to use a new digital technology, I can resolve the issue by using available resources.	21
I can proactively use digital technology to learn the latest nursing knowledge and skills.	25
I can accurately hand over information and nursing processes related to patients using digital collaboration systems (eg, EMR, PACS, in-hospital messenger, etc).	36
Organizational influence	
I am interested in new digital changes that benefit patient care.	19
I reflect on my values and norms that may affect patient privacy in the digital clinical environment.	12
I can encourage organizational members who attempt change by learning new digital technologies.	41
I understand the importance of using new digital technologies for advancing the nursing field.	18
I feel a sense of accomplishment when I effectively perform nursing tasks using newly acquired digital technology.	27
I can help improve organizational members' digital competencies for better work performance.	42
I strive to achieve organizational goals by introducing new digital technologies and resources.	38

Discussion

Principal Findings

This study was conducted to develop a tool to measure digital leadership among clinical nurses, based on the instrument development steps proposed by DeVellis and Thorpe [24]. The research was carried out in 2 phases: the development of preliminary items and the evaluation of the instrument's validity and reliability.

During the item development phase, a conceptual framework was established by integrating the components of digital leadership identified in previous concept analyses and literature reviews on digital leadership in clinical nursing. Preliminary items were selected from the initial items through a content validity assessment by experts, followed by cognitive interviews and a pilot survey, which were used to derive the final set of preliminary items. Throughout this process, expert feedback and identified issues were systematically reviewed and refined.

In the instrument evaluation phase, data were collected from 446 clinical nurses through an online survey. A random sample of 223 responses was used for EFA, and another 223 responses were used for CFA. Construct validity was tested through these analyses, and convergent validity was assessed by examining the correlation with instruments measuring nursing informatics competency and self-leadership. Internal consistency reliability was confirmed with a Cronbach α of 0.95.

The final tool developed through this study consists of 29 items across 4 factors: 8 items for the ability to use digital technology, 5 items for digital safety management, 8 items for a digital collaboration mindset, and 8 items for organizational influence. The tool uses a 5-point Likert scale for self-report surveys, with a total score range from 29 to 145 points. Higher scores indicate a higher level of digital leadership among clinical nurses. Overall, the developed scale demonstrated strong reliability and validity for assessing digital leadership in clinical nursing practice. However, the tool did not fully satisfy the criteria for discriminant validity. Even when variables are used as conceptually independent constructs, correlations between related factors are common in practice [29]. This is consistent with findings from a study on the development of an integrated nursing leadership scale for Korean nurses [41], which also reported overlaps among constructs such as data management and communication technologies. In particular, relatively high correlations were observed between the ability to use digital technology and organizational influence, as well as between digital collaboration mindset and organizational influence. These results suggest that while the factors are conceptually distinct, they may be closely related in actual clinical settings where digital competencies are integrated with leadership behaviors. Although some aspects of discriminant validity were supported, these findings indicate that the boundaries between certain factors were not clearly distinguished. Despite these limitations, this tool has the advantage of including items that measure competencies needed to adapt to rapidly changing digital health care environments, such as work performance, learning, and adaptability [42]. Accordingly, future research is needed to more clearly distinguish the unique conceptual domains measured by each factor. Furthermore, the "digital safety management" factor included fewer items compared to other factors. Given the importance of patient safety and information security in digital health care environments, future research should consider expanding and refining items in this domain to enhance the comprehensiveness of the scale.

Given that leadership competencies required in digitally transforming health care environments are increasingly complex and diverse [13], this DLS-CN reflects the unique characteristics of Korean clinical settings and is the first scale of its kind to undergo statistical validation. Nevertheless, because data collection was conducted via an online survey using convenience sampling, caution is needed when interpreting the results. Additionally, the scale was developed for general clinical nurses and excluded nurses with less than 1 year of experience, nurse managers not involved in direct care, and those in administrative or educational roles, thereby limiting its generalizability. Moreover, the study did not include test-retest reliability, which represents another limitation.

Based on these findings, several implications can be drawn. In particular, the developed digital leadership scale should be applied to nurses from diverse countries and cultural backgrounds, as well as to nurses in various roles and settings, such as hospitals, community health centers, and educational institutions. Repeated studies are recommended to verify the reliability and validity of the instrument in diverse environments.

Future research should use this tool to assess digital leadership levels and develop tailored educational or intervention programs that enhance digital leadership according to workplace and contextual characteristics.

In addition, as this scale may be applicable not only to health care professionals but also to professionals in management, public administration, and related fields, further research should explore its broader applicability across disciplines.

Conclusions

The DLS-CN, developed through this study, is a systematic tool designed to measure and evaluate digital leadership among nurses in clinical practice settings. The DLS-CN consists of 4 core domains: ability to use digital technology, digital safety management, digital collaboration mindset, and organizational influence. It proposes a new standard for nursing leadership in health care environments driven by digital technologies.

XSL•FO
RenderX

In particular, the tool is useful for developing various educational programs aimed at identifying emerging nurse leaders and enhancing the digital leadership of clinical nurses in hospital environments where frequent changes in digital health care systems, technologies, and organizational structures occur. Furthermore, the development of this tool confirms that digital leadership extends beyond the mere acquisition of digital skills, encompassing the competence of clinical nurses to actively engage in and lead change. This is a meaningful contribution to the study.

Since this tool was developed based on data collected from clinical nurses in South Korea, and the items were created accordingly, further validation studies are needed in diverse health care settings and across cultural contexts. In the rapidly evolving digital health care environment, this tool can serve both as a foundational resource and a structured instrument for strengthening clinical nurses' digital leadership.

Abstract

Background: Digital literacy has become a core competence for nursing faculty to adapt to the digital transformation of education, improve teaching quality, and cultivate innovative nursing talents.

Objective: This study aimed to investigate the digital literacy status and influencing factors among nursing faculty in colleges and universities in Fujian province, China.

Methods: A cross-sectional survey analysis was conducted among 339 participants from July 2023 to June 2024 by selecting nursing faculty from 3 medical universities and 5 colleges in Fujian province. A general information questionnaire and a teacher digital literacy questionnaire (designed based on the artificial intelligence–enhanced technological pedagogical content knowledge theoretical model) were used to conduct the survey. The questionnaires included the following dimensions: an intelligent integration ethics layer (digital social responsibility), attention to the moral boundaries of applying technology; an awareness layer (digital awareness), the willingness to actively adapt to technological changes; a knowledge layer (digital technology knowledge and skills), mastery of the integration point of intelligent tools and subject teaching; an ability layer (digital application), the ability to design intelligent teaching plans; and a thinking layer (professional development; innovative thinking for the critical integration of technology). Statistical analysis included descriptive statistics, a 1-way ANOVA, Pearson correlation analysis, and multiple linear regression (using SPSS 28.0 software).

Results: The overall digital literacy of the nursing faculty was at a medium level (mean score 101.92, SD 16.47), with the highest score in digital awareness (mean 20.21, SD 9.43) and the lowest score in digital technology knowledge and skills (mean 9.68, SD 2.92). For the dimension of digital technology knowledge and skills, both age (β=−.142; *P*=.009) and years of teaching (β=−.147; *P*=.006) were significant negative predictors. Regarding digital application, age was found to be a significant negative predictor (β=−0.124; *P*=.02) but teaching experience was a positive predictor (β=0.123, *P*=.02). Similarly, age also had a significant negative impact on the professional development dimension (β=−.153; *P*=.005) and the overall digital literacy level (β=−.136; *P*=.01).

Conclusions: The digital literacy of nursing faculty is at a medium level, with especially low scores in technical knowledge. Age and teaching experience are key influencing factors. Recommendations to promote balanced development of awareness and skills include providing targeted training for senior faculty, integrating courses with clinical practice, optimizing the allocation of digital resources, promoting interdisciplinary cooperation, and strengthening ethical and safety training.

Introduction

Background

With the rapid advancement of the digital age, the education sector is experiencing a profound digital transformation. In this context, the digital literacy of faculty members has emerged as a central topic in the digital transformation of education. Currently, the international community has established a relatively comprehensive development system for faculty digital literacy. Through policy frameworks, standard setting, resource support, and assessment mechanisms, this system has integrated faculty digital literacy into the faculty education system, thereby promoting the digital transformation of education [1-3]. The Chinese government has actively advanced educational modernization through initiatives such as the "China's Education Modernization 2035" blueprint [4], the World Digital Education Conference [5], and the national smart education public service platform. These endeavors indicate a global transition in education systems from information infrastructure to digital empowerment and intelligent innovation, representing a systematic breakthrough in the digital transformation of education [6].

Although digital technology has been preliminarily implemented in medical education, there are still significant gaps in its application to nursing education. In particular, research on how nursing faculty can effectively use digital technologies to enhance processes in nursing education and optimize practical training outcomes remains insufficiently studied. During the digital transformation of nursing education, the development of digital literacy among college nursing faculty has emerged as a crucial factor in ensuring the effectiveness of pedagogical digitization [7]. While most nursing faculty recognize the necessity of integrating digital technology into teaching practices, they also report facing significant challenges in achieving the effective integration of technological tools in teaching due to inadequate digital literacy levels [8] and imbalanced resource allocation [9,10]. Faculty members also demonstrate significant deficiencies in the design, implementation, and evaluation of digital teaching and learning processes [11,12]. Moreover, the existing digital education model has not yet achieved the expected results in stimulating students' learning motivation [13,14]. Previous studies have also confirmed [15,16] that digital technologies play a key role in clinical scenarios, simulation skills training, and distance learning. Their use enhances students' learning experiences and enables faculty to effectively explain complex operations and nursing concepts [17,18].

Technological pedagogical and content knowledge (TPACK) is a comprehensive framework that identifies well-defined types of knowledge required for effective teaching of subject knowledge enhanced by technology adaptation [19]. The AI-TPACK (artificial intelligence–technological pedagogical content knowledge) framework offers a vital analytical tool, with its 5-layer model (encompassing ethical, awareness, knowledge, competency, and cognitive dimensions) providing a systematic approach to assessing educators' digital literacy [20]. This model emphasizes the integration of technology, pedagogy, and ethical considerations.

However, existing research predominantly focuses on general disciplines, neglecting nursing-specific contexts, and often prioritizes technical operational skills over ethical and pedagogical integration. The results of a recently published cross-sectional study showed that the digital literacy of academic nurse educators was at a moderate level and revealed relevant influencing factors [21]. Although existing studies have initially revealed the value of digital literacy in nursing education, there are still research shortcomings in investigating the digital literacy level at nursing faculty institutions and analyzing the influencing factors.

Objective

This study exhibited a broader sample coverage during the selection of research participants. The research group encompassed both clinical teaching faculty and college nursing faculty, thereby representing an instructional design that fully aligned with the core characteristics of the dual faculty within the AI-TPACK theoretical framework of the nursing program. Through standardized data collection, the system of influencing factors and empirical findings that have been identified significantly augment the comprehensiveness and objectivity of the research results. Furthermore, in response to the pressing requirement for the integration of nursing professional development and digital teaching, this study aimed to analyze the digital literacy status of nursing faculty in colleges and universities and examine their influencing factors through a cross-sectional survey, thereby providing a robust foundation for the formulation of precise and effective competency development strategies and the enhancement of digital teaching quality.

Methods

Ethical Considerations

This study was approved by the Bioethics Review Committee of Fujian Medical University (FJMU174) and conducted in strict compliance with the Declaration of Helsinki. All participants provided written informed consent after receiving detailed explanations regarding the research objectives, procedures, and potential risks. Participants received the appropriate compensation for their time and effort upon completion of the study. To ensure data confidentiality, personal information was anonymized and stored securely using encrypted storage methods.

Instrument Design

A cross-sectional survey was conducted from July 2023 to June 2024. This study was designed to comprehensively capture the current state of digital literacy among nursing faculty at 5 clinical colleges and 3 medical universities in Fujian province, China, thereby facilitating an effective assessment of the current situation and its associated influencing factors without the need for a long-term follow-up study. The inclusion criteria for this study were as follows: (1) nursing faculty in undergraduate colleges and universities or those involved in clinical nursing teaching; (2) ≥1 year of nursing teaching experience; and (3)

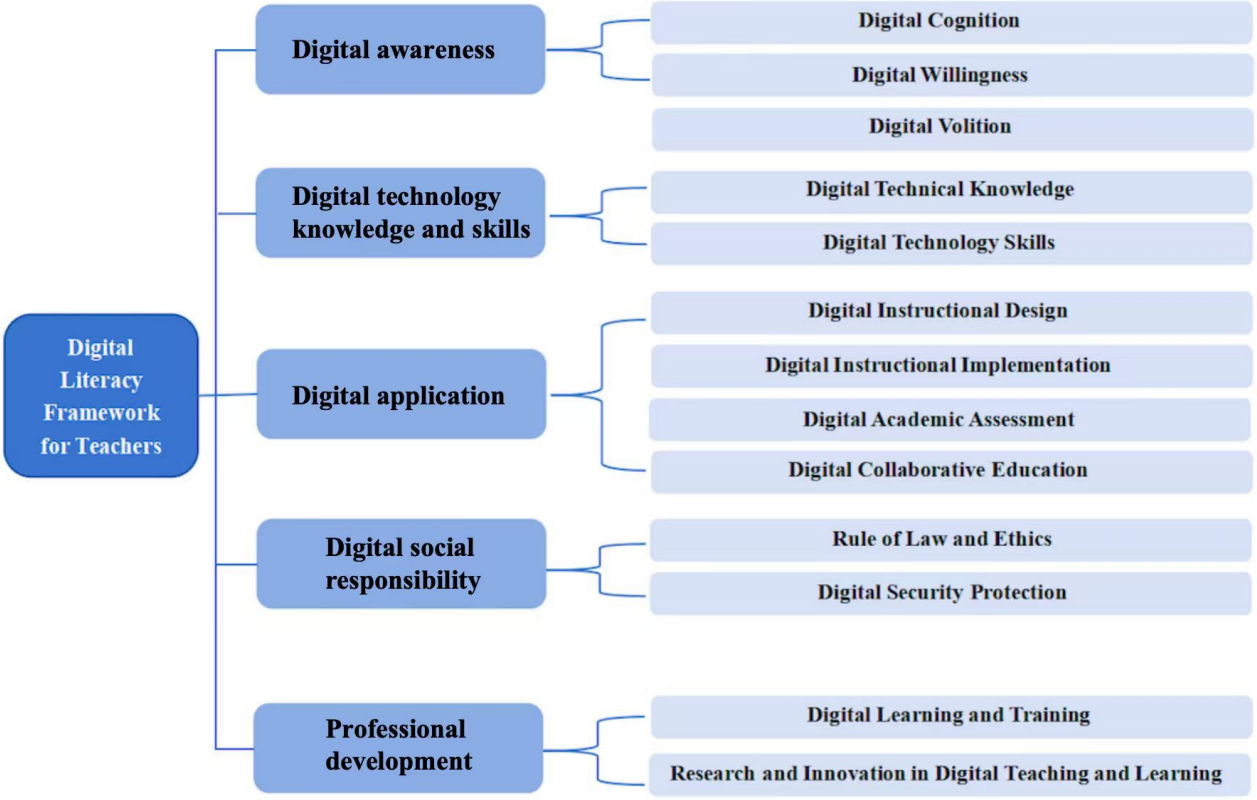
XSL•FO
RenderX

provision of informed consent to participate in this study. The exclusion criteria included faculty who were not on duty due to sick leave, personal leave, maternity leave, or further studies. Our sample size was computed using the Soper online sample size calculator, with an expected effect size of 0.15, a statistical power of 0.85, a probability level of 0.05, and a minimum sample size of 140. In total, 339 participants were included in this study, thereby meeting the requirements of statistical efficacy.

Data Measurements

The questionnaire for this study contained 2 parts and took approximately 15 to 20 minutes to complete. As a core research instrument, it effectively enables standardized data collection from nursing faculty in universities in Fujian province. In addition, the tool assessed multiple dimensions of digital literacy and digital technology participation in a structured and easily analyzed format. The tool is aligned with China's digital literacy agenda and thus demonstrates appropriateness and reliability at both the cultural and semantic levels.

Section A: General Information



The general information questionnaire investigated the basic demographic characteristics of nursing faculty in colleges and universities. It included gender, age, education level, type of teaching, years of teaching experience, and professional title.

Section B: Nursing Faculty Digital Literacy Questionnaire

We adopted the Teacher Digital Literacy Industry Standard (2022) [6] and adjusted the questionnaire based on the AI-TPACK theoretical framework to align with our research objectives. It included the intelligent integration ethics layer (digital social responsibility), attention to the moral boundaries of technology application; the awareness layer (digital awareness), the willingness to actively adapt to technological changes; the knowledge layer (digital technology knowledge and skills), mastery of the integration point of intelligent tools and subject teaching; the ability layer (digital application), the ability to design intelligent teaching plans; and the thinking layer (professional development), the innovative thinking for the critical integration of technology. The questionnaire included 5 first-level dimensions, 13 second-level dimensions, and 28 third-level dimensions, mainly investigating the level of digital literacy among nursing faculty in colleges and universities. A 5-point Likert scale was used, with scores ranging from 1 for "strongly disagree" to 5 for "strongly agree," and total scores ranging from 28 to 140, with higher scores indicating higher levels of digital literacy among university nursing faculty.

Following iterative discussions among the research team that culminated in the development of the preliminary questionnaire, a rigorous expert validation process was conducted. The selection criteria mandated the inclusion of senior professionals holding associate professor or higher academic ranks with a minimum of 10 years of professional experience in relevant disciplines. The expert panel was strategically composed to encompass cohorts of both nursing education specialists and educational technology experts, ensuring comprehensive domain coverage. Considering the discipline-specific characteristics of nursing and the practice-oriented nature of instructional scenarios, this study systematically refined 28 core dimensions from the educational industry standards through a 2-round Delphi expert consultation process (Figure 1).

Figure 1. Digital literacy framework for nursing faculty.

XSL•FO
RenderX

The reliability of the questionnaire was assessed by pilot testing among 80 college nursing faculty. The Cronbach α of the faculty digital literacy questionnaire was tested to be 0.931, and the Kaiser-Meyer-Olkin value was 0.837, indicating a good level of reliability and validity and fully supporting the questionnaire's scientific rigor in terms of cultural adaptation and semantic validity.

Data collection for this study was officially initiated after ethics approval by the relevant institutional review board, and the questionnaires were collected from July 2023 to June 2024. The research team used the Questionnaire Star platform to administer the electronic questionnaire, which was sent to the nursing faculty in the form of a QR code after obtaining administrative approval from the participating organizations (including academic institutions and hospital nursing departments). Standardized procedures were strictly followed during survey implementation: a uniformly prepared informed consent form and standardized instructions were used, and anonymized data collection was performed after obtaining written informed consent from the study participants. Two master's degree nursing students independently verified the data through the platform's backend, eliminating questionnaires with logical errors and regular responses to ensure the validity of the datasets. Finally, the raw data were stored in an encrypted laptop, and only the researchers in the project team had access to the data.

Data Analysis

Statistical analysis was conducted using SPSS (version 28.0; IBM Corp). Normally distributed continuous variables, including dimension scores, were expressed as mean (SD). Categorical variables such as gender and professional titles were described using frequencies and percentages. Bivariate correlations between variables were examined using Pearson correlation analysis, and multiple linear regression analysis was conducted to identify the predictors of digital literacy dimensions. Before interpreting the regression coefficients, collinearity diagnostics were performed to ensure the stability of the model. An α level of .05 was considered statistically significant.

Results

Sample Characteristics

The study population comprised 339 nursing faculty members from higher education institutions. In total, 343 questionnaires were distributed, yielding a response rate of 98.83% (n=339). Among the respondents, 302 (89.1%) identified as female and 37 (10.9%) as male. Age distribution showed a predominant concentration in the ≤45-years age group (n=326, 96.2%). The vast majority (n=336, 99.2%) held bachelor's degrees or higher educational qualifications. Teaching experience was primarily within the 0- to 10-year range for 218 participants (64.3%). Additionally, 328 (96.6%) participants held intermediate-level academic titles or higher. Further demographic characteristics are detailed in Table 1.

Digital Literacy Score Among Nursing Faculty

The study revealed that nursing faculty exhibited a moderate level of overall digital literacy (mean 3.64, SD 0.59). Among the 3 dimensions assessed, digital awareness demonstrated the highest proficiency (mean 4.04, SD 0.88), whereas digital technology knowledge and skills had the lowest score (mean 3.23, SD 0.78). Digital application (mean 3.32, SD 0.88), digital social responsibility (mean 3.72, SD 0.85), and professional development (mean 3.97, SD 0.85) were also demonstrated at a moderate level. Further details are shown in Table 2.

XSL•FO
RenderX

Table . Faculty scores on digital literacy level 1 dimensions (N=339).

Dimension	Items, n (%)	Score, mean (SD)	Score per item, mean (SD)
Digital awareness	5	20.21 (9.43)	4.04 (0.88)
Digital technology knowledge and skills	3	9.68 (2.92)	3.23 (0.78)
Digital application	9	29.86 (10.30)	3.32 (0.88)
Digital social responsibility	6	22.33 (6.44)	3.72 (0.85)
Professional development	5	19.84 (5.13)	3.97 (0.85)

Comparison of Digital Literacy Scores of Nursing Faculty With Different Characteristics

The results showed statistically significant differences among faculty members across different age groups in the dimensions of digital technology knowledge and skills (P=.003), digital application (P=.04), and professional development (P<.001). Significant differences were also observed among faculty members with different years of teaching experience in the dimensions of digital technology knowledge and skills (P=.02) and digital application (P=.03).

Factors Influencing the Dimensions of Faculty Digital Literacy

Variables with statistically significant differences in each dimension of digital literacy of nursing faculty in colleges and universities with different characteristics (age and years of teaching experience) were selected as independent variables, and each dimension was analyzed using multiple linear regression models as the dependent variable. The variance inflation factor for all independent variables was close to 1 (ranging from 1.003 to 1.007), which is well below the threshold of 5, indicating no multicollinearity issues in the model.

The results of the regression analysis are presented in Table 3. The result showed that age and years of teaching experience were significant predictors of specific dimensions of digital literacy, while sex, education level, and professional titles did not show statistically significant effects. Specifically, for the dimension of digital technology knowledge and skills, both age (β=−.142; P=.009) and years of teaching (β=−.147; P=.006) were significant negative predictors. Regarding digital application, age was found to be a significant negative predictor (β=−.124; P=.02), but teaching experiences show a positive predictor (β=.123; P=.02), suggesting that teaching experience may play a positive role in promoting teachers' digital application capabilities, possibly due to accumulated practical experience in integrating digital tools into teaching over time, whereas age might be associated with differences in adaptability to new digital application scenarios. Similarly, age also had a significant negative impact on the professional development dimension (β=−.153; P=.005) and the total digital literacy level (β=−.136; P=.01).

Table . Standardized coefficients (β) for factors influencing digital literacy among nursing faculty (N=339)[a].

Variables	Digital consciousness	Digital technology knowledge and skills	Digital application	Digital social responsibility	Professional development
Gender	0.007	−0.01	−0.002	0.006	0.015
Age (y)	−0.03	−0.142[b]	−0.124[c]	−0.03	-0.153[b]
Education level	0.058	0.0003	0.046	0.017	0.046
Teaching experiences	−0.04	−0.147[b]	0.123[c]	−0.023	−0.054
Professional title	0.013	−0.067	0.075	0.009	−0.008

[a]All variance inflation factor values were close to 1 and below the threshold of 5, indicating that there was no issue of multicollinearity among the variables.

Correlation Analysis of the Dimensions of Digital Literacy Competence of Nursing Faculty

Correlation analysis showed that the overall digital literacy level of nursing faculty in colleges and universities was significantly and positively correlated with all dimensions (P<.001). In addition, the dimensions were positively interrelated, indicating mutual reinforcement among them. Details are presented in Figure 2.

Figure 2. Correlation coefficients between digital literacy and dimensions of nursing faculty.

Discussion

Principal Findings

Our study's findings on nursing faculty's digital literacy scores reveal a nuanced landscape of technological competence, with significant implications for nursing education and practice. The moderate overall digital literacy score (mean 3.64, SD 0.59) suggests that while nursing faculty possess a foundational understanding of digital tools, there remains considerable room for enhancement, particularly in the realm of digital technology knowledge and skills (mean 3.23, SD 0.78), which emerged as the weakest area. This finding is consistent with another study on intergenerational differences in digital competence among faculty [22].

This deficit may hinder faculty's ability to fully leverage advanced technologies in clinical training and patient care, potentially limiting the integration of innovative educational methods such as virtual simulations or AI-driven learning platforms.

The higher proficiency in digital awareness (mean 4.04, SD 0.88) indicates that nursing faculty are generally cognizant of the importance and ethical considerations surrounding digital technology use. This awareness is crucial for maintaining patient confidentiality and navigating the digital health care environment responsibly [23,24]. However, the average scores in digital applications (mean 3.32, SD 0.88), digital social responsibility (mean 3.72, SD 0.85), and professional development (mean 3.97, SD 0.85) suggest a gap between theoretical understanding and practical application. Although faculty may recognize the value of digital tools in education, their limited skills in digital technology knowledge and skills may prevent them from effectively implementing these tools in real-world scenarios [25,26].

The statistically significant differences in digital literacy scores across age groups and years of teaching experience highlight the dynamic nature of technological competence in nursing education. Older faculty members and those with longer teaching experience exhibited lower scores in digital technology knowledge and skills and digital applications, likely due to generational differences in technology exposure and the rapid evolution of digital tools in health care [27,28]. To address this gap, medical schools should develop tailored digital training curricula specifically designed for senior faculty. These programs should be structured to accommodate their unique learning needs and pace, ensuring gradual proficiency in basic digital technology knowledge and skills [29,30].

Furthermore, the findings reveal that faculty members' years of teaching experience also exert a certain influence on their digital literacy levels, which is reflected in a negative correlation

XSL•FO
RenderX

with the dimension of digital technology knowledge and skills, and a positive correlation with the dimension of digital application. Pairwise comparative analysis focusing on the digital technology knowledge and skills dimensions indicated that faculty with more than 11 years of teaching experience exhibited lower willingness to learn digital technology knowledge and skills than those with <5 years of experience. Consequently, this reduced willingness translated to lower levels of mastery of relevant technological knowledge and skills, consistent with the results of previous studies [31]. This phenomenon may be attributed to the dual professional obligations of collegiate nursing faculty, who must concurrently fulfill clinical responsibilities and pedagogical duties [32]. Empirical investigations have demonstrated a statistically significant positive correlation between teaching tenure and burnout prevalence, particularly among faculty with more than a decade of pedagogical experience. Additionally, although experienced faculty possess rich pedagogical expertise accumulated through prolonged teaching practice, they often exhibit diminished motivation for ongoing professional development in emerging digital technologies. Such practitioners' technological knowledge is frequently confined to foundational competencies acquired during initial training phases, resulting in a growing disconnect with rapidly evolving digital innovations [33,34]. This stagnation impedes the systematic advancement of faculty digital technological knowledge and pedagogical skills, thereby constraining their ability to align with contemporary educational transformation requirements and ultimately hindering their capacity to cultivate digital literacy commensurate with the demands of modern education digital paradigm shift.

Additionally, the study showed that faculty members' years of teaching experience were positively correlated with the digital application dimension. This seems to contradict the finding that age was negatively correlated with the digital application dimension; however, we should analyze the effect of years of teaching experience on the level of faculty' digital literacy, all other influences being equal. This phenomenon may be attributed to some interrelated factors. Nursing faculty who have been teaching for a long time usually show significant advantages in the application of digital technology by virtue of their rich accumulation of teaching experience [35]. Research has shown that they are able to systematically screen high-quality digital educational resources (eg, innovative teaching tools such as virtual simulation experiment platforms) that meet the teaching objectives based on the laws of students' cognitive development, rather than unilaterally pursuing technological novelty to gain short-term attention [36]. Empirical research has shown that experienced faculty members are more adept at realizing the organic integration of traditional teaching methods with digital resources, such as visual case analysis method and multimodal narrative teaching method, among other innovative practices [37]. This model of digital application based on teaching a needs-driven approach has led to a significant professional advantage in the dimension of technology application.

The regression analysis provided nuanced insights into the factors shaping nursing faculty's digital literacy, with age and years of teaching emerging as the most robust predictors, while demographic variables such as gender, education level, and professional title showed no statistically significant effects. First, the consistent negative associations between age and multiple dimensions of digital literacy—including digital technology knowledge and skills, digital application, professional development, and overall digital literacy—align with prior research on generational differences in digital competency [38]. This pattern likely stems from a combination of cognitive, attitudinal, and structural factors: older faculty may face age-related declines in technological learning efficiency, experience anxiety or avoidance toward emerging digital tools due to past unsuccessful attempts, and prioritize traditional pedagogical approaches honed through decades of practice over innovative digital methods. Compounding these challenges, institutional resource allocation often prioritizes younger faculty for digital training, leaving senior educators with limited opportunities to update their skills amid heavy administrative and research responsibilities [39,40]. The significant negative relationship between years of teaching and digital technology knowledge and skills further underscores the impact of professional tenure on digital adaptation. While experienced faculty may develop sophisticated digital application strategies rooted in pedagogical expertise, their motivation to acquire new technical knowledge tends to wane over time. This stagnation can be attributed to factors such as burnout from long-term dual clinical and teaching responsibilities [41], as well as a reliance on foundational technological skills acquired during initial training, which may become increasingly outdated in the face of rapid digital evolution [42].

Notably, the absence of significant effects for gender, education level, and professional title suggests that digital literacy disparities in this context are primarily driven by generational and career-stage factors rather than demographic or hierarchical differences. This finding challenges assumptions that higher academic credentials or professional status correlate with greater digital proficiency, highlighting the need for targeted interventions that transcend traditional institutional hierarchies. The low variance inflation factor values (1.003 - 1.007) confirm the absence of multicollinearity, ensuring the reliability of the regression model. This strengthens confidence in the observed relationships between age, teaching tenure, and digital literacy outcomes.

Limitations

Despite the insightful findings, this study is not without limitations that warrant consideration. First, the data were exclusively collected from nursing faculty in universities and clinical colleges located in Fujian province. While the sample provides valuable regional insights, its geographic focus restricts the generalizability of the results, particularly beyond southern China. Future research would benefit from expanding the sampling frame to include diverse geographic regions, institutional types, and health care settings to enhance the external validity of conclusions. Second, the cross-sectional research design used in this study allows for the examination of correlations between variables at a single time point but cannot establish definitive causal relationships. A longitudinal

XSL•FO
RenderX

research design, which tracks changes in digital literacy over time alongside potential influencing factors, would be necessary to disentangle these causal pathways. Finally, the reliance on self-reported questionnaires may introduce response bias, as participants might overestimate their digital skills due to social desirability or lack objective awareness of their competency gaps. Subjective perceptions of digital literacy could thus compromise the accuracy and authenticity of the data. To mitigate this limitation, future studies should integrate objective assessment tools.

Conclusions

This study highlights the critical importance of cultivating digital literacy among nursing educators, whose overall proficiency remains at a moderate level. Gaps persist in the dimensions of digital technology knowledge and skills, necessitating efforts to bridge theory and practice while enhancing applied operational capabilities. Age significantly influences nursing faculty's digital literacy, with younger instructors demonstrating greater advantages in digital teaching, underscoring the necessity for continuous professional development. The impact of teaching experience proves more complex, which further emphasizes the urgent need for medical schools to develop differentiated strategies to enhance digital literacy. Against this backdrop, strengthening digital technology training, implementing systematic instruction on digital ethics and information security, and cultivating educators' digital social responsibility are key to enhancing nursing education quality. For senior faculty, tailored training programs should prioritize gradual, context-specific skill-building that aligns with their learning pace and pedagogical needs, while addressing attitudinal barriers through peer mentoring and success case sharing. For midcareer faculty, interventions should focus on bridging the gap between existing pedagogical expertise and emerging digital tools, fostering innovative integration rather than technical replacement. By addressing age-related and tenure-related disparities, institutions can cultivate a more inclusive digitally competent nursing faculty workforce, better positioned to meet the demands of modern health care education. Future research should examine regional and institutional variations in nursing educators' digital literacy to explore personalized training strategies for targeted improvement.

Abstract

Background: The Saudi Arabian health care sector is transforming under Vision 2030 with the goal of digitizing its services. This necessitates a digitally prepared nursing workforce; however, there is evidence suggesting that nursing students have limited informatics competency and that these skills are minimally covered in their training programs.

Objective: This study measured the baseline informatics competency and technology self-efficacy of undergraduate nursing students at the University of Hail, Saudi Arabia.

Methods: Using a descriptive cross-sectional design, data were collected from 243 undergraduate nursing students at the University of Hail through an online survey. The survey measured demographics, informatics competency (Canadian Nurse Informatics Competency Assessment Scale), and digital technology self-efficacy. Data analysis used descriptive statistics, 2-tailed *t* tests, ANOVA, and hierarchical regression analysis.

Results: Students reported a moderate level of informatics competency, with a mean Canadian Nurse Informatics Competency Assessment Scale item score of 2.57 (SD 0.84) on a scale from 1 to 4. They also showed moderate to high self-efficacy for digital technology, with a mean item score of 2.7 (SD 0.56) out of 4. Informatics competency scores were substantially higher in students with prior informatics training and frequent electronic health record exposure. In the underpowered exploratory hierarchical regression model, self-efficacy for digital technology showed a small positive association with informatics competency that approached statistical significance; however, the overall model was not statistically significant and explained only a limited proportion of the variance.

Conclusions: This single-site study of undergraduate nursing students at the University of Hail found moderate self-reported informatics competency despite higher digital technology self-efficacy, indicating a need for strengthened informatics education to support the Saudi Vision 2030. While underpowered, exploratory analyses and self-report data mean that these institution-specific findings should be interpreted cautiously and used primarily to guide future multisite and mixed methods research.

KEYWORDS

informatics competency; digital health; nursing education; self-efficacy; electronic health records

Introduction

The digital health revolution continues to transform health care delivery and organizational structures. Advances in artificial intelligence (AI), telemedicine, and electronic health records (EHRs) now support safer, more efficient, and data-driven care [1,2]. Consequently, preparing a globally competent health informatics workforce is essential for implementing these innovations and enhancing clinical outcomes [3,4].

Nurses comprise the largest portion of the health care workforce and are in a pivotal position to integrate technology into direct patient care. Informatics competency, the integration of computers to manage and communicate data [3], is a key skill that nurses must develop. Equally important is technology self-efficacy, or nurses' confidence in using digital tools in clinical and educational settings [5]. Despite the wide recognition of their importance, the inclusion of nursing informatics in undergraduate curricula varies considerably worldwide. Studies from North America, Europe, Africa, and

XSL•FO
RenderX

the Asia-Pacific region have shown significant differences in course content, learning opportunities, and assessment methods used to measure informatics competency among nursing students [6-8].

International initiatives such as Technology Informatics Guiding Education Reform and the Canadian Nurse Informatics Competency Assessment Scale (C-NICAS) promote the formal integration of informatics into nursing education. However, their adoption varies widely across different programs and countries. This study used the C-NICAS as an assessment tool and conceptual framework to identify key informatics competency domains among undergraduate nursing students. Despite the global use of such frameworks, empirical studies have shown that students and new graduates consistently self-report only basic to intermediate proficiency, often lacking hands-on experience with clinical information systems. This highlights the persistent gap between curriculum design and real-world practice [4].

As part of Vision 2030, Saudi Arabia has launched a nationwide digital health initiative to modernize health care using digital tools, telemedicine, and AI [9-11]. Initiatives such as the Healthcare Sector Transformation Program aim to transform service delivery, improve accessibility, and enhance the quality and efficiency of care, reflecting a national focus on developing a data-driven, patient-centered workforce. However, studies have shown that Saudi nursing students and practicing registered nurses have lower informatics competency than their international counterparts, particularly those in countries with more advanced digital technologies and infrastructure [12-15]. Despite significant reform efforts, the integration of informatics into Saudi nursing education has not yet reached the level observed in many other high-income countries, indicating the need for targeted policy and curriculum intervention.

Although many global models advocate for the integration of informatics into nursing education, very little research has addressed this topic in Saudi Arabia. Few studies have investigated how prepared nursing students are for digital health roles or how their informatics competency relates to their confidence with technology, both of which are important factors for successfully joining today's digital health care workforce. These research gaps need to be filled so that evidence can guide faculty training and improve nursing curricula, especially given the Vision 2030 focus on digital health. This study measured the baseline informatics competency and digital readiness of nursing students at the University of Hail, Saudi Arabia. The goal was to provide local data that address a known gap in preparing Saudi Arabia's future nurses to work in digitally transformed health care settings.

Methods

Study Design

This study adopted a descriptive cross-sectional design to assess perceived informatics competency and digital technology self-efficacy among undergraduate nursing students using an online self-assessment survey.

Study Population and Sampling

Voluntary participation in an electronic survey allowed for data collection from undergraduate nursing students at a university in Hail, covering students from the first to fourth years (levels 1 - 4) of the Bachelor of Nursing program. The target population was all undergraduate nursing students enrolled in the Bachelor of Nursing program at the University of Hail during the 2024 - 2025 academic year (levels 1 - 4 and interns). The source population comprised all students with an active institutional email address on the official program mailing list at the time of data collection. Therefore, the accessible sampling frame consisted of this official mailing list of currently enrolled undergraduate nursing students, which was used to distribute a single open invitation to participate in the study.

Students were eligible if they (1) were currently enrolled as undergraduate nursing students in levels 1 to 4 at the University of Hail, (2) were able to read and understand English (the language of instruction), and (3) had an active institutional email account. Students on academic suspension, on long-term leave, or who had withdrawn from the program at the time of data collection were excluded from the study.

A convenience sampling approach was used in which all eligible students from the source population were invited to participate. This strategy was practical, cost-effective, and enabled the coverage of the broadest possible segment of the accessible student population. In this context, convenience sampling reflects all students who chose to respond to the open email invitation rather than a preselected subgroup. All invitations were distributed via the official undergraduate nursing program's email list. Because the list is updated dynamically, the exact number of invitations sent could not be confirmed, but it approximately matched the total number of eligible students. The survey was conducted using Google Forms. A total of 260 students started the survey, of whom 93.5% (243/260) completed it and were included in the analysis. In total, 6.5% (n=17) of the responses were excluded due to substantial missing data (more than 20% of the items were unanswered). Because the total number of active student email accounts at the time of the survey could not be verified, the exact response rate could not be calculated. However, program records indicated that the mailing list approximately matched the total number of enrolled and eligible students.

For inferential analyses involving year level, only students in levels 1 to 4 were included, excluding interns because their internship year is structurally distinct from the numbered academic levels. To reduce potential selection bias, all eligible undergraduate nursing students on the institutional mailing list were invited to participate using the recruitment protocol described in the Data Collection section.

Study Size

A priori power analysis indicated that at least 315 respondents were required to achieve 80% power at a 95% confidence level for medium effects in ANOVA, 2-tailed *t* tests, and regression analyses. Therefore, the final analytic sample of 243 respondents was underpowered for confirmatory inferential analyses but

XSL•FO
RenderX

was considered adequate for descriptive and exploratory correlational analyses.

Instrument

The questionnaire was divided into 3 sections to capture comprehensive participant information. The first section collected general demographic data, including age, sex, academic year, prior experience with electronic medical records, and self-assessed computer proficiency. These variables provided a contextual background for interpreting the findings in the subsequent sections.

The second section assessed participants' informatics competency using the 21-item C-NICAS version 2 with permission from Kleib and Nagle [3]. This student-focused instrument has been adapted and validated for undergraduate nursing students across multiple international contexts, supporting its suitability for this population and enabling cross-study comparison. Originally developed and psychometrically validated among registered nurses in Alberta, Canada, the scale has also undergone cross-cultural validation, supporting its use in international benchmarking.

The C-NICAS includes 4 subscales: foundational information and communications technology (ICT) skills, information and knowledge management, professional responsibility and accountability, and use of ICTs in the delivery of care. These domains align with the core competencies relevant to the digital health ecosystem in Saudi Arabia. The instrument was administered in English, consistent with the language of instruction at the study site. Participants self-reported their competency using a 4-point Likert scale ranging from 1 ("not competent") to 4 ("very competent"). The total scores ranged from 21 to 84 and were categorized into 4 levels: not competent (21-41), somewhat competent (42-62), competent (63-83), and very competent (84). The scale demonstrated strong internal consistency (Cronbach α=0.93 overall and 0.74 - 0.89 for the subscales).

The final section measured digital technology self-efficacy using a revised 17-item version of the questionnaire by Hughes [16]. This scale complements the C-NICAS by assessing students' confidence in their ability to use digital technology. Responses were recorded on a 4-point Likert scale ranging from 1 ("strongly disagree") to 4 ("strongly agree"). In total, 12 items were reverse coded, and 5 items (1, 7, 8, 11, and 16) were positively coded. The mean scores ranged from 1 to 4, with higher scores indicating greater self-efficacy. The scale demonstrated strong reliability, with the Cronbach α exceeding 0.90 in both the original study and the sample in this study.

Both informatics competency and digital technology self-efficacy were assessed using self-report measures. Although both instruments have strong psychometric properties, self-reported data may be subject to bias and inaccurate self-assessment, potentially leading to over- or underestimation of actual competency and confidence levels.

Data Collection

An ethical recruitment plan was developed. Nursing students were invited through email, which contained an invitation letter, a survey link, an information sheet, and a consent statement. The invitation highlighted the purpose of the research, the importance of the study, and the possible implications of the study for nursing informatics research.

Reminder emails using a predetermined protocol were sent to encourage response; the first reminder was sent 24 to 48 hours after the initial email, followed by another one 3 to 7 days later, with a total of 3 to 5 reminders sent throughout the data collection period. Google Forms was used for the survey because of its accessibility and reasonable data storage capacity.

Statistical Analysis

Data analysis was performed using SPSS (version 29.0; IBM Corp) and the Python software (Python Software Foundation). Item-level missing data were minimal (<5% for all variables). Continuous items with less than 5% of missing data were imputed using item-specific means and categorical variables using the mode. Given the low proportion of missing data, this approach was unlikely to bias the descriptive estimates, although it may have slightly attenuated the variance in the inferential analyses.

Statistical assumptions were assessed prior to the inferential analyses. Descriptive statistics, including measures of central tendency (mean, median, and mode) and variability (SD), were calculated for key variables, such as C-NICAS and digital technology self-efficacy scores. Inferential analyses included Pearson correlation to examine relationships among variables, independent-sample *t* tests, and one-way ANOVA to assess group differences.

Hierarchical multiple regression was conducted using 4 models to identify the predictors of informatics competency. Potential confounders (age, sex, academic level, prior informatics training, and previous EHR exposure) were included; however, given the underpowered sample and limited variables, residual and unmeasured confounding (eg, informal IT training or personal interest in technology) cannot be excluded.

The significance level was set at an α value of .05. Effect sizes were interpreted using the Cohen standards for correlations (small=0.10; medium=0.30; large=0.50), and *F* change statistics were used to assess changes in R^2 values across regression models. As the final sample was below the a priori target (N=243 vs 315), all inferential analyses should be considered exploratory and hypothesis generating rather than confirmatory.

Ethical Considerations

Institutional review board approval from the University of Hail (H-2024-437) was obtained prior to data collection. Participation was entirely voluntary and no financial compensation was provided to the participants. All procedures were conducted in accordance with the ethical standards of the Research Ethics Committee and the 1964 Declaration of Helsinki and its subsequent amendments.

Informed consent was obtained from all students prior to accessing the online survey and questionnaire. Participation was entirely voluntary, and students had the right to withdraw at any time without adverse academic consequences. To preserve participants' anonymity, no personal identifiers (such as names

XSL•FO
RenderX

or email addresses) were collected through Google Forms, and the researchers did not link any responses to individual participants. The dataset was stored on a secure, password-protected server, and access was limited to the research team members.

This study posed an extremely low risk as it involved noninvasive procedures and presented no more than minimal risk to the participants. The participants' normal coursework was not affected, and it was clearly stated that their decision to participate or not would have no impact on their academic status or their relationship with faculty members.

Results

Table 1 presents the study's 243 undergraduate nursing student participants from Saudi Arabia, with most being young adults aged 21 to 25 years (n=116, 47.7%) and only 7% (n=17) aged 26 years and above. The sample was predominantly female (n=159, 65.4%). Students were distributed across academic levels, with interns accounting for the largest group (n=63, 25.9%) and year level 8 students representing the smallest group (n=13, 5.3%). The participants were nearly equally divided between those with informatics training (n=124, 51%) and those without (n=119, 49%). Comfort with digital technology varied, with 41.2% (n=100) expressing discomfort and 22.2% (n=54) remaining neutral on the subject. EHR experience ranged from 40.3% (n=98) having occasional exposure to 29.6% (n=72) having no prior experience with EHRs. Most participants demonstrated good technology accessibility, with 82.3% (n=200) using technology daily for educational purposes and 65% (n=158) reporting excellent home internet access. Regarding career intentions, most (n=130, 53.5%) planned to pursue clinical care, whereas 13.6% (n=33) remained undecided about their future nursing career paths. A comparison between respondents and nonrespondents was not possible because identifiable sampling frame data were unavailable; therefore, some nonresponse bias cannot be excluded.

[a]EHR: electronic health record.

Table 2 presents the self-reported C-NICAS item scores from the 243 undergraduate nursing students (mean 2.57, SD 0.84 on a scale from 1-4); the median was 2.50 (2.00-3.00). Regarding the total number of C-NICAS scores, the largest percentage of students (n=116, 47.7%) achieved a score of "somewhat competent"; 21.4% (n=52), or nearly 1 in 5, achieved a score of "not competent"; 23.9% (n=58) achieved a score of "competent"; and only 7% (n=17) achieved a score of "very competent." When reviewing the subscales, the "foundational ICT skills" subscale had the highest average C-NICAS item score (2.62, SD 0.93), followed by the "use of ICT in the delivery of patient care" (2.60, SD 0.85) and "professional and regulatory accountability" (2.56, SD 0.88) subscales, whereas the "information and knowledge management" subscale had the lowest average C-NICAS item score (2.51, SD 0.86). Most students reported that they rated themselves as somewhat competent on 3 out of the 4 subscales (n=75, 30.9% - n=106, 43.6%), and most students who evaluated themselves as not competent did so on the "foundational ICT skills" subscale (n=58, 23.9%) and least frequently in the "use of ICT in the delivery of patient care" subscale (n=43, 17.7%). Overall, students self-reported moderate levels of informatics competency; however, many rated themselves as only somewhat competent in practically all areas of informatics competency.

Table . Nursing students' perceptions of informatics competency (Canadian Nurse Informatics Competency Assessment Scale [C-NICAS] mean item scores; N=243).

Scale and subscale	Item score (1-4), mean (SD)	Item score (1-4), median (IQR)	Range	Not competent, n (%)	Somewhat competent, n (%)	Competent, n (%)	Very competent, n (%)
NI[a] competency (overall C-NICAS)	2.57 (0.84)	2.50 (2.01–3.10)	1-4	52 (21.4)	116 (47.7)	58 (23.9)	17 (7)
Foundational ICT[b] skills	2.62 (0.93)	2.66 (2.00–3.33)	1-4	58 (23.9)	75 (30.9)	78 (32.1)	32 (13.2)
Information and technology management	2.51 (0.86)	2.50 (2.00–3.00)	1-4	57 (23.5)	103 (42.4)	57 (23.5)	26(10.7)
Professional and regulatory accountability	2.56 (0.88)	2.50 (2.00–3.17)	1-4	52 (21.4)	102 (42)	58 (23.9)	31 (12.8)
Use of ICT in the delivery of patient care	2.60 (0.85)	2.66 (2.00–3.17)	1-4	43 (17.7)	106 (43.6)	65 (26.7)	29 (11.9)

[a]NI: nursing informatics

[b]ICT: information and communications technology.

The mean self-efficacy score for the use of digital technologies was 2.7 (SD 0.56) on a scale from 1 to 4. This indicates that, as a group, the nursing students reported a moderate to high level of confidence in using digital technologies. Because the mean score of 2.7 is above the scale midpoint, the students' digital technology self-efficacy can be considered strong.

Table 3 presents the data on informatics competency and digital technology self-efficacy among Saudi nursing students. There were no statistically significant differences in the C-NICAS total scores by year level for students in levels 3 to 8 (P=.48) or in the digital technology self-efficacy mean item scores (P=.87). The mean C-NICAS total scores ranged from 48.3 (SD 15.6) in level 3 to 55.4 (SD 17.9) in level 7, whereas the digital technology self-efficacy mean item scores ranged from 2.5 (SD 0.5) to 2.7 (SD 0.2) on a scale from 1 to 4. Exploratory t test analysis showed that students with prior informatics training had higher mean C-NICAS total scores (55.0, SD 15.8) than those without such training (50.6, SD 15.2; P=.005), whereas their mean digital technology self-efficacy item scores were similar (2.6, SD 0.4 vs 2.5, SD 0.5; P=.53). Exploratory ANOVA further indicated that students with no EHR experience had the lowest mean C-NICAS total scores (48.4, SD 16.1) compared with higher scores among those with occasional (53.4, SD 17.2) or frequent (54.9, SD 13.4) EHR use (P=.002); in contrast, digital technology self-efficacy mean item scores remained relatively stable across groups with EHR use (2.5, SD 0.4 to 2.6, SD 0.4; P=.40).

XSL•FO
RenderX

Table . Overall competency and self-efficacy levels by year level, prior informatics training, and routine electronic health record (EHR) use.

Variable	C-NICAS[a] total score (21-84), mean (SD)	*P* value	DT-SE[b] item score (1-4), mean (SD)	*P* value

[a]C-NICAS: Canadian Nurse Informatics Competency Assessment Scale.

[b]DT-SE: digital technology self-efficacy.

Table 4 illustrates the preliminary correlational findings showing a positive association between digital technology self-efficacy and 3 of the informatics competency subscales. The strongest correlation was with foundational ICT skills (r=0.181; P=.002), followed by professional responsibility and accountability (r=0.157; P=.002) and use of ICT in care delivery (r=0.113; P=.02). However, the strongest correlations were between the competency subscales themselves, indicating a good level of internal connection. Specifically, the strongest correlation was between professional accountability and use of ICT in care (r=0.794; P=.001), followed closely by the correlation between foundational ICT skills and professional accountability (r=0.769; P=.001) and between foundational ICT skills and use of ICT in care (r=0.765; P=.001).

Table . Correlation between competency and self-efficacy.

	DT-SE[a]	Foundational ICT[b] skills	Professional and regulatory accountability	Use of ICT in the delivery of patient care
DT-SE				
r	1	0.181	0.157	0.113

[a]DT-SE: digital technology self-efficacy.

[b]ICT: information and communications technology.

[c]Not applicable.

Table 5 presents the outcomes of an exploratory hierarchical multiple regression analysis examining potential predictors of informatics competency measured using the C-NICAS score. In model 1, age and sex were entered, yielding an R value of

XSL•FO
RenderX

0.013 and an adjusted R^2 value of 0.005 ($F_{2,243}$=1.611; P=.20), with no significant predictors. In model 2, year level (fourth-eighth) and internship status were added, resulting in an R value of 0.031 and an adjusted R^2 value of −0.002 ($F_{8,237}$=0.950; P=.48), and again, no significant predictors emerged. In model 3, prior EHR experience and informatics training were added, yielding an R value of 0.054 and an adjusted R^2 value of 0.013 ($F_{10,235}$=1.330; P=.22), with no variables reaching statistical significance. In the final model (model 4), the mean digital technology self-efficacy score was included, resulting in an R value of 0.069 and an adjusted R^2 value of 0.022 ($F_{11,234}$=1.577; P=.11). Digital technology self-efficacy showed at most a weak, borderline association with informatics competency (B=4.34; P=.05), accounting for only a negligible proportion of the variance; thus, it cannot be considered a robust predictor in this sample. Given the modest effect size, nonsignificant overall model, and sample size (N=243) falling below the a priori target (N=315), these regression results should be interpreted with caution and viewed as exploratory and hypothesis generating rather than confirmatory. Overall, the hierarchical models explained only a small proportion of the variance in informatics competency scores.

Table . Hierarchical multiple regression models predicting informatics competency[a].

Model	Variables entered	R^2	Adjusted R^2	F test (df)	P value	Significant predictors (final model)
1	Age and sex	0.013	0.005	1.611 (2, 243)	.20	None
2	+ year level (fourth-eighth) and internship	0.031	−0.002	0.950 (8, 237)	.48	None
3	+ EHR[b] exposure and informatics training	0.054	0.013	1.330 (10, 235)	.22	None
4	+ mean digital technology self-efficacy score	0.069	0.022	1.577 (11, 234)	.11	Digital technology self-efficacy (B=4.34; P=.05)

[a]None of the hierarchical regression models reached conventional statistical significance for the overall F test, and the explained variance was small (maximum adjusted R^2=0.022); therefore, these findings, including the trend-level association for digital technology self-efficacy, should be interpreted as exploratory and preliminary.

[b]EHR: electronic health record.

Discussion

Principal Findings

Overview

This study assessed the baseline informatics competency of undergraduate nursing students at a single institution in Hail, Saudi Arabia, based on self-reported informatics competency scores and revealed a moderate level of competency. Most students rated themselves as somewhat competent. These results suggest that current competency levels may be insufficient to fully support the digital health priorities articulated in the Saudi Vision 2030, indicating the need to further strengthen informatics education and experiential exposure to digital health systems. In addition, this study found that students with previous informatics education had notably higher C-NICAS scores than those without.

Informatics Competency Levels

A moderate level of informatics competency, particularly lower scores in the “information and knowledge management” and “professional responsibility and accountability” subscales, suggests that students may have basic ICT and documentation abilities but lack proficiency in the critical appraisal and interpretation of digital health data, application of ethical and regulatory standards, and more advanced use of information to support clinical decision-making. These deficits are likely related to limited systematically integrated informatics content within undergraduate curricula and restricted, structured exposure to digital health systems, particularly EHRs.

Several studies in Saudi Arabia have reported that nursing students possess basic informatics knowledge but do not consistently achieve high competency [17,18]. The reported deficits are greatest in clinical informatics and applied computer skills, highlighting the gap between knowledge and practice [17,18]. Students proficient in everyday digital technologies often struggle to transfer these abilities to clinical settings that require specific informatics skills [18].

Other studies have reinforced the distinction between digital literacy and informatics competency [19,20]. Nursing students may report moderate or high digital health literacy; however, literacy alone does not ensure competency in critical appraisal, data interpretation, or safe clinical application [19]. Although there have been initiatives to integrate digital skills into the curriculum, the lack of rich experiential learning limits students’ progression to competent or advanced informatics levels [20]. Considering these findings and the C-NICAS results in our study, Saudi nursing programs should substantially expand informatics content across all years of study. The lowest mean scores in the “information and knowledge management” subscale underscore the need for modules that teach students to manage, retrieve, and critically appraise health information from electronic databases. These competencies can be addressed

XSL•FO
RenderX

through dedicated courses and by embedding informatics objectives into existing theory and clinical units, consistent with recent international recommendations [21].

Experiential learning should include structured, practice-focused engagement with digital health systems, particularly EHRs, as students with previous EHR exposure in this study demonstrated higher competency. This aligns with evidence that greater EHR integration is associated with improved informatics knowledge and skills [22,23]. Targeted faculty development is also needed so that educators can confidently model and assess informatics competency in both classroom and clinical settings.

Academic-practice partnerships that provide students with supervised access to real-time informatics environments can help bridge the gap between classroom learning and clinical practice. Aligning these curricular changes with the Saudi Vision 2030 health strategy is essential for building a digitally competent nursing workforce capable of supporting high-quality, safe care across the kingdom [9,23,24].

Digital Technology Self-Efficacy

The moderately high digital technology self-efficacy found in this study likely stems from students' heavy use of digital tools, widespread internet access, and regular use of online resources. Although digital technology self-efficacy showed a small positive correlation with informatics competency, the hierarchical regression model was not statistically significant, explaining only 2% of the variance. Consequently, digital technology self-efficacy was not a strong predictor of informatics competency in this study. These results should be viewed as hypothesis generating, suggesting a weak association that requires confirmation in larger samples. Instead of making causal claims, the focus remained on robust descriptive and bivariate findings such as differences related to prior informatics training and EHR exposure.

A trend toward increased willingness to use digital technologies for educational and clinical purposes is evident among frequent users, consistent with the findings of another study [25]. Recent studies indicate that nursing students generally show acceptable preparedness for AI-based health care and a positive disposition toward digital health tools [14,25,26]. In Saudi Arabia, nursing students typically view e-learning favorably and are proficient in technology-rich environments, particularly in blended learning contexts [14]. Prior experience and digital literacy remain key indicators of self-efficacy and preparedness in undergraduate nursing education [26].

Nevertheless, digital technology self-efficacy varies considerably [14,27]. Many students remain uncomfortable with digital technologies, especially when transitioning to clinical settings [27]. Furthermore, some are dissatisfied with e-learning due to a lack of in-person interaction and support [14]. Technical difficulties, inconsistent design, and inadequate training can also decrease confidence and satisfaction [14].

These findings suggest that access and exposure are insufficient. Students face obstacles in applying personal technological knowledge to professional contexts and require more support [14,26]. Digital technology self-efficacy can be strengthened by providing consistent hands-on digital literacy education, individualized assistance, and cooperative blended learning environments. Nursing programs should also build strong technological foundations and systematically collect student feedback to improve these environments [14,26]. This approach will help students develop the confidence and skills necessary to use digital tools effectively in both study and practice.

Role of EHR Experience

Early experience with EHRs significantly influences nursing students' informatics competency. There was a positive relationship between EHR experience and informatics competency: students who reported frequent or occasional hands-on use had higher competency scores than those with little or no experience. Practicing informatics in real time enhances the translation of abstract knowledge into practical applications, and providing students with authentic EHR experiences contributes to their clinical preparation [28]. Exposure to educational EHR platforms requires technical proficiency and has broader implications for student learning.

Institutions emphasizing EHR use can expect improved student performance in informatics assessments and application skills, resulting in graduates who are better prepared for practice [22]. Structured exposure to EHR systems may also enhance students' documentation skills, clinical reasoning, and compliance with professional and regulatory requirements. As the demand for advanced informatics skills increases, all students will need structured and equitable access to educational EHR systems [28].

Digital literacy and informatics competency gaps are most apparent when students transition from classrooms to clinical settings. Many students who do not receive instruction on EHR use feel unprepared to document clinical data or perform other informatics tasks [28]. Furthermore, obstacles during clinical rotations are multifaceted, including limited EHR access, unclear learning expectations, and variable guidance from preceptors [28].

Similar concerns exist in the Saudi context, where inequitable student access to EHRs at clinical sites has been identified [15]. Nursing programs should provide comprehensive longitudinal training programs that address EHR use. Furthermore, programs should incorporate simulated or laboratory-based experiences that replicate authentic informatics tasks such as data retrieval, clinical decision-making, and regulatory documentation [21].

Finally, partnering with health care organizations can ensure that students have supervised EHR access and clear learning objectives during clinical rotations [28]. These strategies help bridge the gap between basic digital literacy and professional informatics competency, enhancing readiness for real-world practice, increasing patient safety, and creating long-term career opportunities in the digital health care field.

Implications

These results have significant implications for nursing education and policy in Saudi Arabia. Considering the moderate level of informatics competency, curricular reform is needed to align nursing students with the digital elements of Vision 2030. This can be achieved not only by viewing faculty as presenters of

XSL•FO
RenderX

subject matter but also by emphasizing authentic learning experiences. This could be further aided by incorporating a specific informatics module or student engagement activities that rely on EHRs and digital health technologies, which have demonstrated successful clinical experiences in American and Canadian programs. Finally, it is of utmost importance to formalize partnerships between universities and practice settings to ensure that students have authentic experience with real-time informatics in practice settings. These initiatives could yield a digitally competent workforce that can use technology in patient care and contribute to health initiatives in the future.

Conclusions

This single-site survey found that undergraduate nursing students at the University of Hail showed noticeable gaps in informatics competency even though many reported moderate to high confidence in using digital technologies. This highlights the need to revisit the current curriculum considering Saudi Vision 2030 and its emphasis on digital health. The findings also suggest that being comfortable with everyday technology does not necessarily mean that students are prepared with the informatics skills required in clinical settings. Students with prior exposure to informatics content or experience with EHRs generally demonstrated better competency levels. However, the study sample was smaller than originally planned, and the statistical analyses were not sufficiently powered. Therefore, any observed relationship, including the weak link between digital technology self-efficacy and informatics competency, should be interpreted with caution and considered exploratory.

It is also important to note that this study relied on a single-site convenience sample and self-reported data, both of which limit the generalizability of the findings. These factors may also lead to an overestimation of the actual competency levels. Therefore, the results are best understood as specific to this context rather than reflective of all nursing students in Saudi Arabia. Nevertheless, this study offers useful baseline information that can support local curriculum improvements and inform future research, particularly larger multisite or mixed methods studies aimed at strengthening nursing informatics education in the country.

Abstract

Background: Socioemotional competencies (SEC) are essential for nurses to provide quality care and to maintain their own health. Historically underrepresented, nursing programs are changing their curricula to incorporate SEC development more strongly. Although it is recommended to practice SEC during clinical placement, studies on how to support nursing students in developing these competencies are lacking.

Objective: Our study explores second-year nursing students' perceived and actual use of a reflection tool during their first 20-week clinical placement. Designed to support SEC development, the study focuses on how students incorporate the application in their learning process for SEC development.

Methods: An embedded mixed method study was conducted with 15 students from a nursing program in the Netherlands. Qualitative surveys and semistructured interviews were used to capture students' experiences with the application both during and at the end of the clinical placement. Log data from the application provided insight into how the app was used. The mixed methods data were analyzed using warranted assertion analysis.

Results: The app helped students relate learning goals to clinical experiences, identify learning opportunities, and experience a sense of growth. Features that removed practical barriers to reflecting were experienced as most beneficial. Although SEC-focused use was limited (n=7), involved students used the app over a longer period of time and reported greater benefits. Nevertheless, 13 students stopped using the app halfway through their clinical placement, as their attitude shifted from learning to working.

Conclusions: This study gives a rich description of how nursing students used a reflection app to structure their learning process during clinical placement. It reveals that smartphone-based reflection supports students in clinical placement learning. Specifically, the app lowers barriers to engaging in structural reflection and decreases the mental burden of self-regulated learning. However, more guidance and a multimodal intervention approach seem necessary for SEC development. Further research into how to account for students' shifting attitudes toward learning is needed.

Introduction

Background

Socioemotional competencies (SEC) play a large role in the day-to-day work of a nurse, both to provide quality care as well as to maintain their own well-being [1-5]. As our understanding of the importance of these nursing competencies grows, so too does the interest in how to effectively teach [3,6-8] and assess [1,9] SEC in nursing programs.

A recent systematic review underlines the importance of developing SEC during clinical practice [10], showing nursing students are unprepared for the social dynamics of the workplace otherwise. Traditionally, however, the focus of clinical placement has been on improving technical skills [11-14]. Concurrently, nontechnical skills such as SEC are expected to

XSL•FO
RenderX

be learned through a social and more implicit learning process [15-17]. The review's findings suggest supporting SEC development within the clinical learning environment requires specific didactical attention. Yet, there is little research on what clinical placement needs or how to implement it there.

Research findings indicate that SEC require nursing programs to adopt active and innovative learning methodologies in their curricula [8,18,19]. Studies show that when reflection is used as an active learning methodology, SEC development is supported [20-23]. Reflection helps students to process their clinical experiences and learn from them [23]. Specific to SEC, reflection can support the development of interprofessional communication and collaboration skills [20,21], as well as a better understanding of oneself and the workplace experience [22-24]. Thus, using reflection specifically to make the implicit learning process of SEC more explicit warrants further exploration.

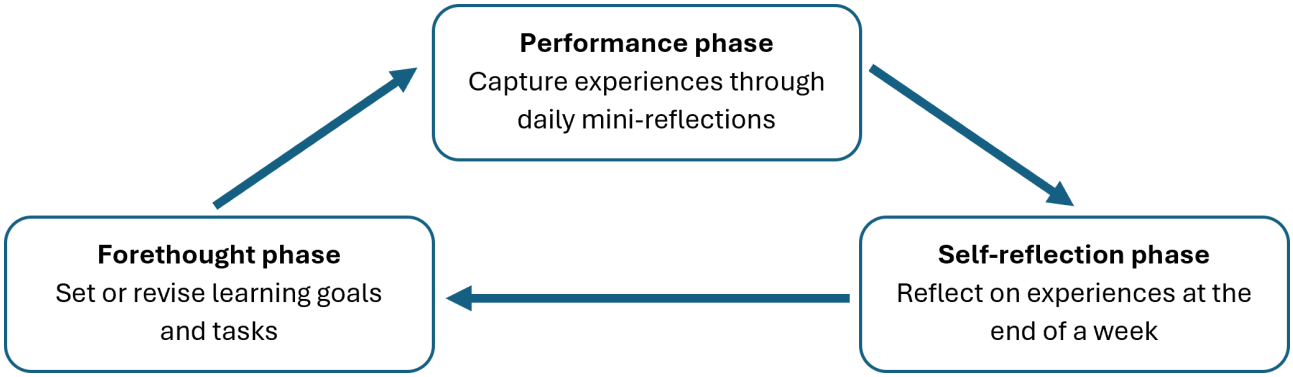
Over the past decades, studies on reflection within clinical placement have explored the potential of smartphone technology for its ease of use and ability to support students' development when workplace coaching is limited [11,14,25,26]. When it comes to clinical skills, research shows this to be an effective approach to improve learning during clinical placement [26-28]. Moreover, many studies show nursing students, educators, and preceptors favor digital apps over paper-based methods of reflection [13,27-31]. Reasons for this preference include greater flexibility, a more convenient method of managing one's reflections, and better visualization of one's progress [29]. Although smartphone-based reflection can support clinical skill development, there is little research on how such apps can support SEC development.

This study aims to address this gap and explore the potential of smartphone-based reflection for SEC development during clinical placement. The study is part of a larger project in which we developed a reflection app called Nurse-IT in co-creation with nursing students and educators. The app aims to help students structurally reflect on their clinical experiences for SEC development purposes.

In the development process of the app, design guidelines from both theory and practice have been translated to concrete design features (eg, daily and weekly reflections). Given the lack of applied research on this topic, our study's main focus is to explore the in situ impact of a SEC-focused reflection app on students' learning processes. By focusing on students' experiences with the app from a learning process perspective, we better understand not just the app's impact, but also how it interacts with the learning environment in which it is introduced. Doing so provides a more nuanced and practical understanding of the developed app and the underpinning design guidelines. This leads us to the following design research question: *How do the app's features impact nursing students' socioemotional competency development during clinical placement?*

To answer this question, we conduct an embedded mixed methods field trial of the Nurse-IT app. By gathering a diverse set of data during the field trial, we aim to get a detailed view on how nursing students incorporate the app's structural reflection in their learning process. We also measure their perception and usage of the app throughout the clinical placement to better understand how usage develops over time.

The App



Design Guidelines

Designing educational interventions requires incorporating and balancing both theory and practice. We began with an overarching learning process based on theory and clinical placement as a learning context. This was developed further into a prototype through co-creation. We briefly summarize the most salient design guidelines and the app itself here.

Theory

The clinical learning experience focuses on learning-by-doing and real-life practice, with students encountering many social situations during a shift. Part of the app's goal is to support students in capturing those moments to be able to reflect and learn from them, facilitating further experiential learning [32]. Moreover, the aim is to empower them to structurally and intentionally work on their SEC, resulting in a self-regulated learning cycle [33] (Figure 1). Finally, as an educational app is dependent on students using it consistently, its design needs to make the primary task (ie, reflection) easy and enjoyable. For this, we used the principles of persuasive systems design [34].

Figure 1. Self-regulated learning cycle which starts at the forethought phase, to then monitor oneself in the performance phase, and to evaluate oneself in the self-reflection phase after which the cycle begins anew.

XSL•FO
RenderX

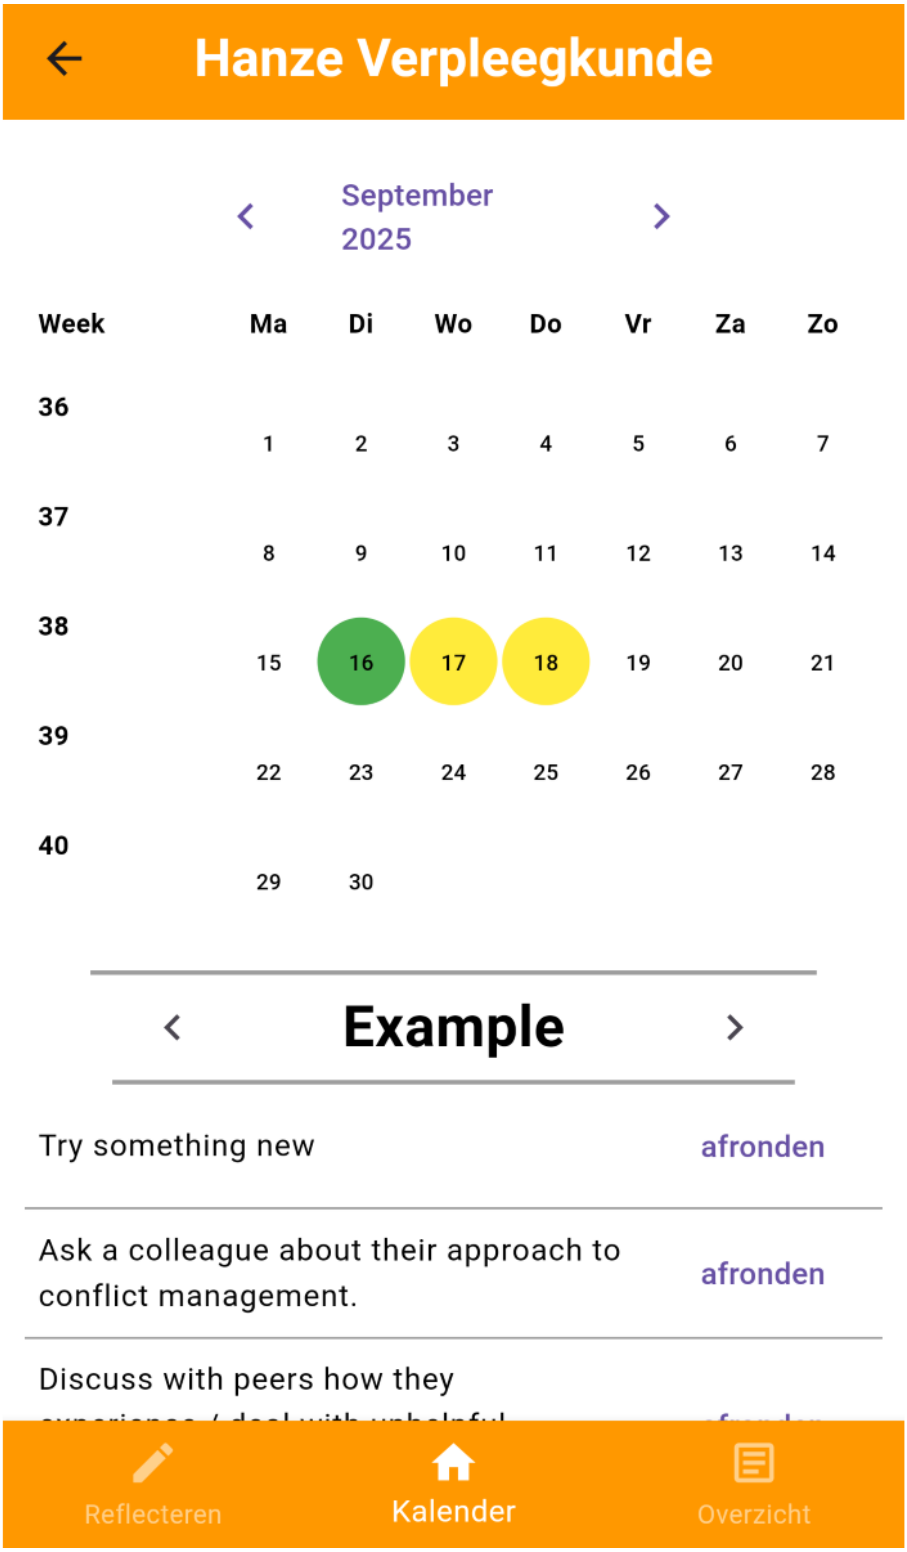
Practice

Nursing students and educators of a nursing program in the Netherlands were involved to make sure that the app's design and user experience align with their needs [11,14,30,35]. Although the overarching learning process was determined beforehand, the co-creative process was necessary to translate it to a design that corresponds with the reality of doing a clinical placement. One outcome of the entirety of the co-creative process was the formulation of five design guidelines:

1. Provide structure, but allow for flexibility: The app needs to scaffold goal-setting and reflection by providing preset questions [36]. Those questions should allow students to express themselves in a way that suits their needs.
2. Low time-investment when capturing experiences: The performance phase requires students to structurally capture their experiences. Given the high workload of clinical placement, capturing those experiences should be quick and easy to do. Even if that means having a low level of reflection.
3. Looking back, but also planning ahead: The app should facilitate students in planning follow-up actions based on what they learned from their reflections.
4. Help me see, monitor, and appreciate my growth: The app needs to summarize and visualize the student's growth toward their learning goals. In doing so, the students should feel in control of their learning process [35].
5. No one has access but me, but I can share things if I want: To further underline student autonomy and learner agency, the app's contents should only be visible to the student [37,38]. Nothing should be assessed unless the student wants to share something themself.

Features of the App

Forethought Phase: Learning Goals and Tasks



Clinical placement requires students to reach specific learning outcomes. Goal-setting helps structure this learning process and represents the forethought phase of self-regulated learning. Moreover, setting goals allows the students to monitor their progress and stay aware of the goals they are working on [39]. Consequently, learning goals are a core feature of the app: students formulate their own or use the curriculum's competencies. They then add a target grade they want to work toward and determine the period in which they want to work on the learning goal (guideline 3).

Another aspect of the forethought phase is planning. Setting a goal is one thing, but breaking it down into smaller, more achievable parts (ie, proximal goals) helps focus students' efforts toward achieving the goal and raises self-efficacy [39]. This also ties into experiential learning's phase of active experimentation. The app facilitates this by allowing students to add tasks to their learning goals (guideline 1).

To further help students be aware of their learning goals and respective tasks, they are placed on the home screen of the app (Figure 2). Here they can navigate between learning goals and check off tasks (guideline 4).

XSL•FO
RenderX

Figure 2. Home screen of the app. The calendar shows a month with 3 completed daily reflections, each represented by a colored dot. The word 'Example' represents a learning goal, with the lines of text underneath each representing an individual learning task.

Performance Phase: Daily Reflections

Daily reflections represent the performance phase of self-regulated learning. The main goal of daily reflections is to have the student self-monitor and evaluate after each shift (guideline 4). To ensure students are willing to do so, we favor a low time investment over achieving deeper reflection (guideline 2) [34]. In doing so, we aim to achieve two things: (1) students record more situations and build up a reservoir of experiences which they can reflect on, and (2) students engage in a frequent and structured way of reflection-on-action and thus have better awareness of their progress (ie, self-monitoring) [33,39].

The daily reflection's design reflects these goals by using features that provide immediate low-level insights and help summarize an experience from both a descriptive (eg, title and tags) and an emotional level (eg, emojis). In terms of evaluation,

XSL•FO
RenderX

the student (1) grades themselves on the learning goal they are writing the reflection for, (2) can write a *tip* for themselves, something they could do differently next time, and (3) can write a *top* (ie, a positive comment) about what the user felt went well. Finally, the student can use a text field to write about the shift in whichever way they want (called "free writing"). It is to be noted that we only require the student to give a grade to their shift; all other features are optional. This way we follow the design guideline of providing structure but allowing for flexibility (guideline 1).

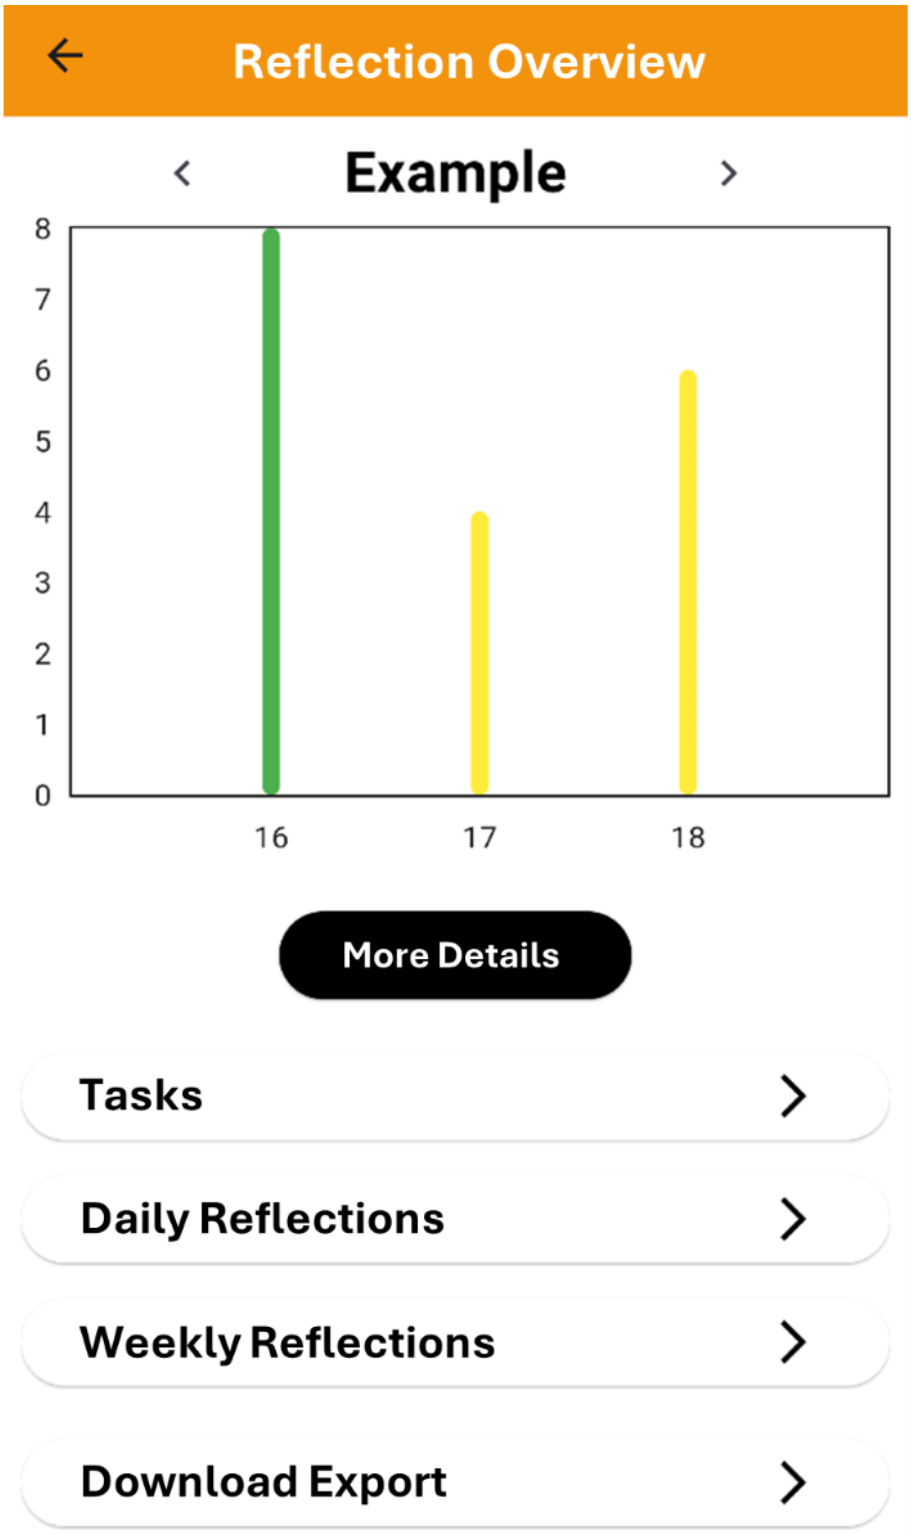
Self-Reflection Phase: Weekly Reflections

With the daily reflections covering the performance phase, the weekly reflections represent the self-reflection phase and the revisiting of the forethought phase of self-regulated learning. Consequently, the main goal of the weekly reflections is twofold: (1) to achieve deep reflection and use different experiences gained through daily reflections, and (2) to review one's progress and make plans for the week to come (guideline 3).

This is translated into the app through a three-step process, aligning with experiential learning principles (and guideline 1):

1. A student looks back at the week and describes what they are proud of and what they found difficult.
2. They choose one of the 2 and reflect on why they feel that way, what situation caused those feelings and how they dealt with the situation, what they learned from the experience, and how they would approach similar situations next time.
3. They review their learning goals and select those that relate to the week's reflection. Learning goals and tasks can be marked as complete, edited, or newly created.

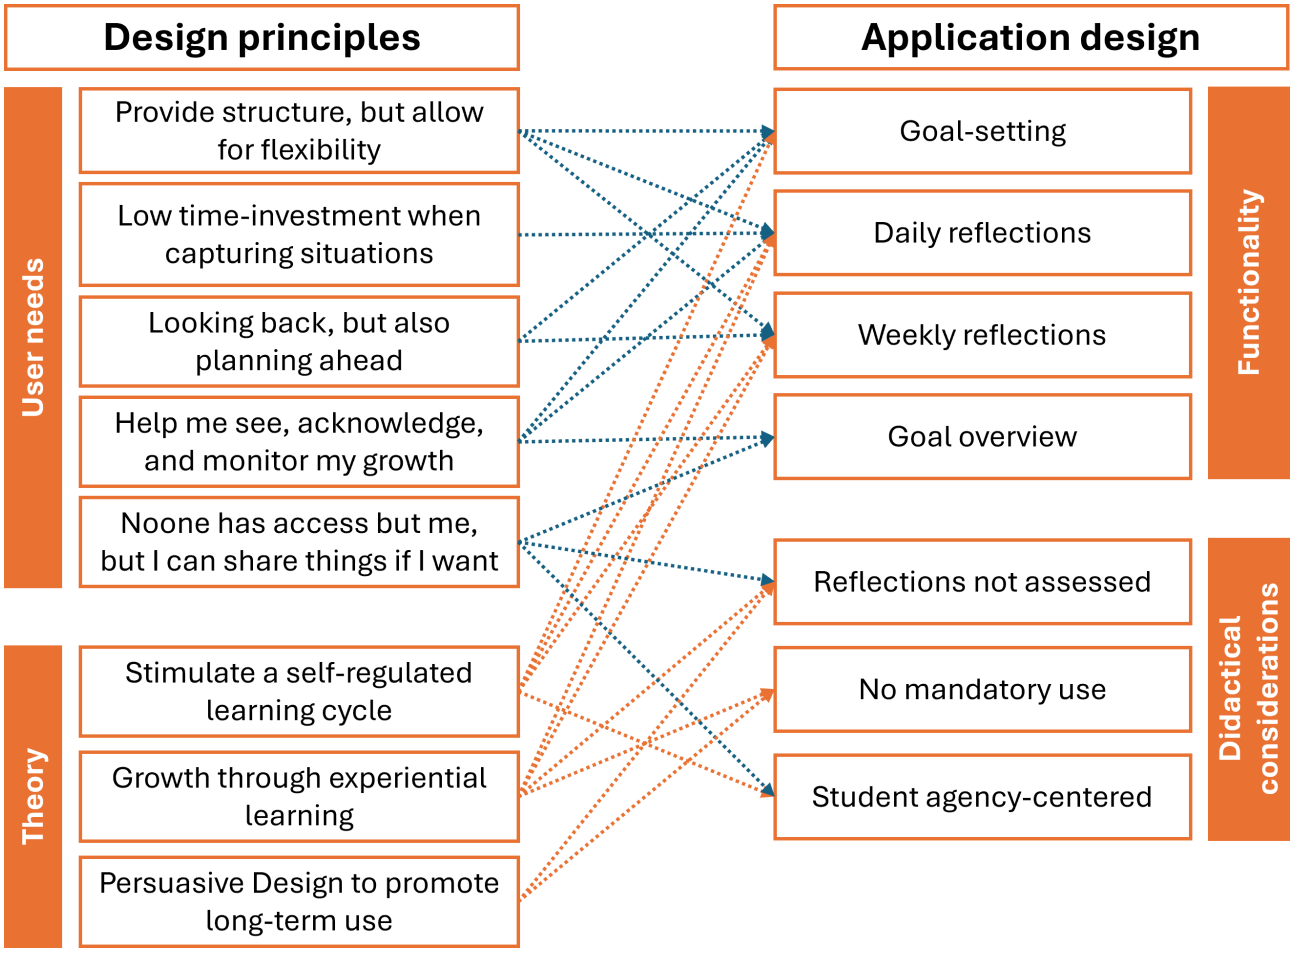
Ideally, a weekly reflection helps students identify when they are stuck in their learning process and need to reach out to others for help. As the reflection app keeps the students' learning goals and reflections private to themselves, only the student can act on app-related insights. This, combined with findings of our co-creative process and earlier work that show students can have trouble identifying such situations [17], made us aim to create triggers for help-seeking behavior.



Learning Goal Overview

Students can review their active and completed learning goals through the overall learning goal overview screen. Here, they can also review their progress on a specific learning goal through the learning goal overview (guideline 4), which harbors all the related daily and weekly reflections, tasks, and visualizes the daily reflection grades over time (Figure 3). As per the design guideline concerning sharing data, this page also allows students to export their learning goals for documentation or coaching purposes (guideline 5).

Having discussed the features of the app, Figure 4 summarizes their connection to the design guidelines.



XSL•FO
RenderX

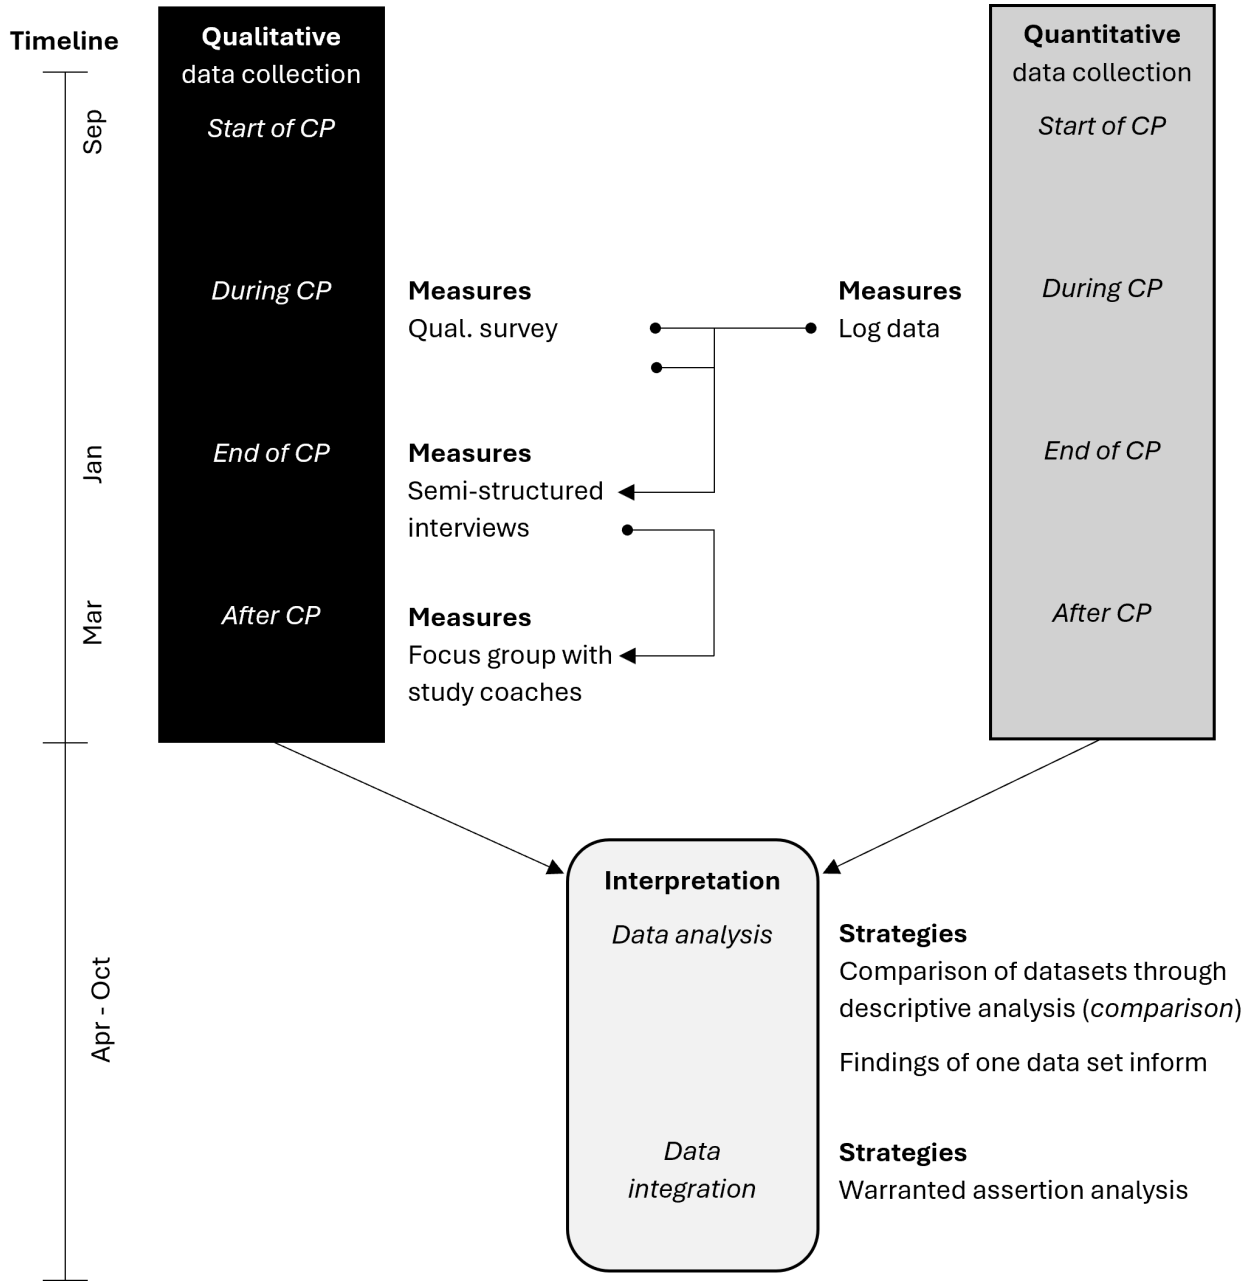
Figure 3. Overview of an example learning goal. The graph shows the grades of three daily reflections, the color indicating the grade they gave themselves (1 - 3 red, 4 - 6 yellow, 7 - 10 green). The 'tasks,' 'daily reflections,' and "weekly reflections" buttons lead to their respective overview pages. Download export provides a spreadsheet version of the learning goal's activities.

XSL•FO
RenderX

Figure 4. Overview of how the design guidelines are instantiated in the design of the app.

Methods

Study Design



The study used an embedded mixed methods research approach within a pragmatist paradigm to capture the potential richness of a naturalistic field trial. The goal of mixed methods research is to integrate knowledge of several methods, both quantitative and qualitative, allowing meta-inferences to be drawn [40]. These meta-inferences aim to explain phenomena in a way that exceeds the sum of a study's parts (ie, each individual method). Thus, describing the selection of methods as well as the purpose and timing of integrating results in mixed methods studies is important.

For this study, reflection contents, open-ended surveys, and interviews give a qualitative perspective on how students used the tool, how that usage developed over time, and a rich description of their context of use. Embedded within this qualitative study are log data. These give a quantitative perspective on how participants engaged with the tool. By combining perspectives, our understanding is informed both from the actual usage of the tool, as well as the participants' context-rich experiences with the tool. Together, both strands help illuminate the app's role within the student's learning process: which parts of the app are used, what needs do they meet, and why?

It is recommended to visualize the mixed methods design in a diagram to condense its complexity in an explainable manner [41]. In Figure 5, we provide a chronological, vertical diagram of the above-mentioned methods. Arrows between methods highlight how insights from one method informed the data collection of another (ie, *building* [40]). Data interpretation (ie, analysis and integration) is simplified in this diagram and will be discussed in the Data Interpretation section.

XSL•FO
RenderX

Figure 5. Visualization of the embedded mixed methods study design. A predominantly qualitative study embedded with a quantitative method to answer the research question from both a perceived and actual use of the app. CP: clinical placement.

Measures

Actual Use of the App

Log Data

In addition to participants' own assessment of their engagement, log data were recorded of in-app activity to capture actual use of the tool. Participants' sessions, the creation of a learning goal or daily reflection, and the usage of tags were logged. Additionally, participants' learning goals, tasks, daily reflections, and weekly reflections were also stored in a database for both quantitative and qualitative analysis.

For the purposes of determining whether students were still active, in-app activity was monitored on a weekly basis. If students had been inactive for over 2 weeks, they were considered to have stopped using the app.

Reflection and Learning Goal Contents

Contents of the reflections and learning goals were included in the study to better understand how the features were used. This helps to further interpret the log data and possibly distinguish different patterns of use (eg, whether SEC were set as learning goals).

Experience Using the App

Qualitative Survey

To understand participants' experiences with the app, we developed a small survey with seven open-ended questions (refer to Multimedia Appendix 1 for the survey questions). These focused on the daily and weekly reflection features, as well as how students experienced the balance between time and the insights they gained from using the app. This survey was set to be distributed three times: the third, fifth, and seventh

XSL•FO
RenderX

week of the clinical placement. The qualitative survey helped capture the early development of the student's engagement with the tool. Due to a severe technical issue further described in the limitations section, only the first 2 surveys were administered. The first on September 19, 2024, the second on October 10, 2024.

Posttrial Semistructured Interview

Semistructured interviews were conducted online between December 18, 2024, and January 22, 2025. Our goal was to understand the role of the app in participants' learning process during the clinical placement (refer to Multimedia Appendix 2 for the interview schema). Participants were reminded to give their open and honest opinion about the app. As other measures already provided a clearer picture of the actual use and, to an extent, what it was used for, the interviews focused on:

1. Participants' context of learning
   - The clinical placement as learning environment
   - Their perspective on the clinical placement (eg, expectations and motivation)
2. Participants' learning process
   - What skills did they focus on, and how did they approach learning itself?
   - How structured and self-regulated was their process?
3. How did those related to the app
   - How did the context of learning influence app use?
   - What was the role of the app in the participants' learning process?

To be able to compare learning processes of active users and students who did not, or hardly, use the app, students who dropped out during the trial were also invited for this interview. For these cases, the last topic focused on why the app was not, or hardly, used.

Posttrial Focus Group With Study Coaches

After the interviews, a coach-perspective was required to verify whether certain observations were commonly seen in the broader student population, or just our sample. Of our invitation to the entire coaching team of this specific clinical placement, 4 coaches agreed to participate. All gave verbal consent (refer to Multimedia Appendix 3 for the topic list). The focus group was conducted on March 18, 2025, took approximately 45 minutes, and focused on (1) students' changing attitude toward learning during the clinical placement, (2) differences between identified groups of students, and (3) level of challenge of the second-year clinical placement.

Data Interpretation

The goal of mixed methods research is to find meta-inferences through the integration of qualitative and quantitative findings. One strategy to do so is through *warranted assertion analysis* [42], which consists of four steps:

1. Organizing the raw data of each individual data set
2. These data sets are then read as a whole, repeatedly, to come to warranted assertions (ie, meta-inferences)
3. Evidence is collected for each warranted assertion
4. Warranted assertions are refined iteratively by looking for disconfirming evidence

This inductive approach toward mixed methods analysis was chosen as each of our measures shed light on a different aspect of the research question. Although some revealed more than others, they needed to be treated equally valuable for meta-inferences to be drawn. Put in Smith's [42] words:

> *That is, whether data happen to be in the form of words or in the form of numbers should not materially affect the process of constructing meaning from them. Both forms of data are symbolic and neither is inherently "harder" or "softer" than the other.*

We will first report our initial analysis on a measure-to-measure basis. We then describe how we integrated qualitative and quantitative data to reach warranted assertions. The findings section will describe the findings of each measure, after which we discuss our warranted assertions in the Discussion section.

Data Analysis Per Measure

Log data were analyzed quantitatively through descriptive measures (medians, means, and SDs when applicable) to see students' actual usage of the app. Students' activity was quantified through (1) the number of days between first and last use; (2) the number of sessions within that time period; (3) the number of learning goals, daily reflections, and weekly reflections created; and (4) the number of tags and emoticons used (both total and average per session).

Learning goal contents were analyzed to see what topics students used and whether they were SEC or clinical skill-related. This was done by (1) creating an overview of all learning goals, categorized per participant; (2) comparing learning goal phrasing; and (3) cross-referencing it with the corresponding daily reflections to see how the learning goal was used in practice. An additional category (introductory period) was later added to refine the categorization.

During this round, reflection contents were only analyzed to get a first impression of how students used both the daily and weekly reflections. This was done by (1) creating an overview of an individual participant's daily and weekly reflections, (2) reading the reflections, (3) summarizing the participant's approach to reflecting (what fields were used and overall focus of the reflection).

The qualitative survey data were analyzed for perceived ease of use and utility of the daily and weekly reflections. Per question, responses were analyzed using content analysis. These results were then compared between the 2 questionnaires to analyze potential differences.

The interview schema was used as a lens to structure the semistructured interview analysis. Each transcript was analyzed separately to describe each student's individual learning process and how they incorporated the app.

Data Integration

The data integration process consisted of repeatedly engaging with the results of the data analyses and the raw data. Performing the data analysis and comparing the results between measures

XSL•FO
RenderX

was the first step in identifying potential warranted assertions. Then, using the semistructured interview findings as a starting point, these potential warranted assertions were refined, and new ones were found by *importing* [40] the other methods' findings one by one. For example, importing the reflection and learning goal contents helped us understand patterns of use in relation to students' approaches to learning and their learning environment.

Throughout this process, the integration shifted between a student-specific focus and an overarching one. Doing so allowed us to scrutinize the warranted assertions for disconfirming evidence (ie, if a student's learning process did not fit an assertion), resulting in a more nuanced analysis.

Recruitment

Procedure

The sample consisted of Dutch nursing students of the Hanze University of Applied Sciences in the Netherlands. Inclusion criteria were students attending their second year and who were going on their first 20-week-long clinical placement.

Students were recruited using convenience sampling through the following means:

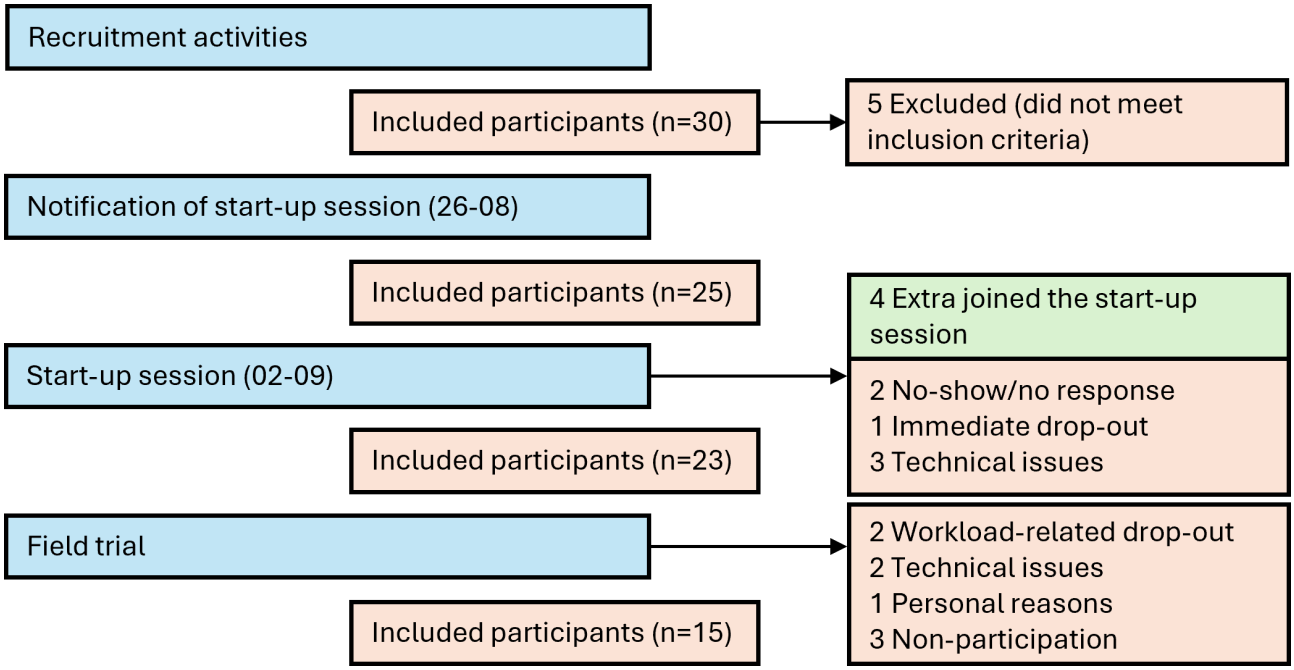
First, a call (and several reminders) was posted on the study program's educational intranet, specifically the clinical placement page where students of our sample were enrolled. It featured a brief description of what the field trial entailed and its goals, a link to sign up, and a reference to the information letter.

Second, an information letter was shared on the same educational intranet page as the call. This letter included an explanation of the goals of the study, what participation entailed, how data would be managed, the potential benefits and risks of participation, and how students could drop out during the study.

Third, an information session was held by the first author (IBB) following a general information session about the clinical placement. In this session, the basic features of the app, the setup of the field trial (eg, what data would be collected and when), and how to sign up were explained.

Finally, the start-up session of the field trial was deliberately planned to follow the main start-up of the clinical placement organized by the study program. This allowed students who had missed the call before the summer break to still sign up. Additionally, as this was the start-up to the curriculum's first clinical placement, this also guaranteed our participants met our inclusion criteria.

The start-up session was given by the first author (IBB), someone the students had no previous relation with and who does not fulfill a role within the curriculum. The session included a reiteration of the study's goals and data collection, an explanation of the features of the app, how students could use it to showcase course-related competencies, and a hands-on support session to help students get the app running on their phones.



Participants

In total, 34 participants signed up for the study, but only 23 participants started. Moreover, 5 were excluded during the screening process as they were 3rd- or 4th-year students, respectively, doing their second and third clinical placement. In total, 6 participants dropped out at the start-up session.

In the first 3 weeks of the trial, we had 5 more dropouts: 2 due to the workload of the clinical placement, 2 due to unsolvable technical difficulties, and 1 due to personal reasons. Moreover, it became clear near the end of our trial that 3 participants had hardly been active in the app, had not filled in any surveys, and did not respond to our interview request. This brings the number of active participants down to 15 (refer to Multimedia Appendix 4 for the demographic data). Figure 6 gives an overview of the process.

XSL•FO
RenderX

Figure 6. An overview of the recruitment process for the field trial.

Ethical Considerations

A risk to study participation was the added workload of maintaining learning goals and reflections in the app, with no guarantee that this work would aid in passing the clinical placement itself. As the clinical placement is partially graded based on personal growth with regard to several learning outcomes (including 2 personal learning goals), we arranged with the clinical placement coordinator that the activity within the app could be used as evidence for such growth. In doing so, we aimed to lower the risk of participation and ensured that students gained something by participating. We prepared alternative material in case technical errors would occur (same format and questions but in separate Word files).

Ethical approval was obtained from the Hanze Ethical Advisory Committee before the commencement of this study (heac.T2024.032).

Informed consent was obtained at the end of the start-up session. Data were stored on the cloud storage of the researchers' university. As multiple data gathering tools were used, participant data were pseudonymized to allow for data comparison and importation. The translation key was stored in a separate cloud storage which only the lead researcher had access to. The data will be deleted 5 years after the project's completion. Due to low response rates to the first questionnaire, a small financial compensation was added to the study. The reasoning behind this choice is discussed further in the Limitations section.

Results

Actual Use of the App

Log Data

All students used learning goals, with the second most used feature being the daily reflections (14/15, 93.3%). Weekly reflections were barely used (8/15, 53.3%), of which only 1 used it multiple times. Emojis were used by a smaller group (6/15, 40%), with half of those users using at least one emoji per daily reflection. Tags were more broadly used (12/15, 80%; mean 1.76, SD 1.63), but intensity of use varied. Moreover, 3 students used tags and emojis frequently, with on average more than 3 tags and 1 emoji per daily reflection.

App usage varied strongly (mean 46.7, SD 20 d), with 3 outliers who used the app for more than 2 months (not the same 3 as the tag- and emoji-users). Most students used the app for 6 weeks in the first half of their clinical placement (9/15, 60%). No one completed goals, with overall goal use showing 3 patterns: creating all learning goals at the start (4/15, 26.7%), creating learning goals throughout clinical placement (6/15, 40%), or only creating a few at the start (5/15, 33.3%). Due to logging issues, we were unable to accurately determine session lengths.

Reflection and Learning Goal Contents

Qualitatively, learning goal contents show three categories: focusing on clinical skills, the introductory period, and SEC goals (refer to Table 1 for an overview). Only half of the students set SEC goals (n=7), whereas nearly all of them set clinical skill (n=13) and introductory period (n=12) goals.

XSL•FO
RenderX

Table . An overview of the 3 identified goal categories, how many students used them, and illustrative examples.

Goal categories	n	Illustrative goals
Clinical skills	13	• "improving practical skills" [Participant 264] • "independently doing the handover to the next shift" [Participant 451]
Introductory period	12	• "getting to know the patients" [Participant 269] • "getting up to speed with protocols" [Participant 380]
Socioemotional competences	7	• "setting boundaries" [Participant 960] • "clearly and empathically react to and give feedback" [Participant 528]

Reflection contents for clinical skill-focused goals included summaries of executed procedures and self-assessments of what went well or needs to be improved. Similarly, introductory period-focused reflections mainly consisted of self-assessments. SEC-focused reflections were often more elaborate, with a stronger focus on emotions and actions. Examples are illustrated in Table 2.

Table . An overview of the three goal categories, their predominant characteristics, and example quotes.

Goal categories and reflection content	Illustrative quotes
Clinical skills	
Summaries	"I washed people only when asked to do so. I emptied catheters. I helped people go to the toilet. I gave medication to a few people, but it was busy so my colleague did most of it herself. I restocked cupboards with towels myself." [Participant 664]
Self-assessment	"Next time, I should ask if I can do something, like wash their back or face." [Participant 269]
Introductory period	
Self-assessment	"I notice that I am starting to feel comfortable with the various clients and that I can talk with colleagues." [Participant 309]
Socioemotional competences	
Focus on emotions and actions.	"I had to do the caretaking tasks for a lady, after which she gave me one task after another while I was still working on the first one. She also said this in a very commanding tone. After this, I stopped and told her that I can only do one thing at a time and that I am doing my best. It frustrated me and made me feel uncomfortable. After that, she apologized and was much calmer. The colleague who was in the resident's living room also said that I had understood the situation well and responded appropriately. This made me feel very good and confident." [Participant 202]

The tip- and top-fields were used often and similarly across goals. The tip-field often being a small, future-action-oriented reflection (eg, "project more confidence" [Participant 402]) related to the described experience, and the top being a reflection on what went well (eg, "indicated more clearly when I didn't understand something" [Participant 246]).

Experience Using the App

Qualitative Surveys

First Survey

The 9 participants who filled out the first version also filled in the second. Moreover, 6 other participants only filled in the second version. Although this limits our potential to compare changes within individual participants, there is enough data to look at more overarching trends.

In line with the log data, results of the first questionnaire show participants appreciate the daily reflection feature (questions 1, 1a, and 3). Specifically, students mention its ease of use:

> *It brings me a lot. And the questions make it easy, so it takes less time.* [Participant 907]

Additionally, they like how the formatted questions provide focus (eg, tip or top):

> *That you can give tips and tops so that you can clearly see what you are doing right and wrong.* [Participant 246]

Finally, students appreciate that these reflections are brief but still provide small, valuable insights:

XSL•FO
RenderX

> *It helps me process things by writing down what has happened, while typing, I have sometimes come to realize things.* [Participant 202]

Some participants remark that it is hard to remind themselves to use the app after a shift, asking for a reminder feature (question 3):

> *It might be nice to have the option to receive notifications. I notice that I quickly forget about it myself.* [Participant 309]

The few students who have used the weekly reflections were positive (question 2 and 2a):

> *Quite a lot, actually! It's nice to have a slightly clearer structure and to answer the questions.* [Participant 926]

However, the majority of the students mention they still have to try out the weekly reflection. Generally, the first questionnaire shows that about a third of the participants engaged little with the app.

Second Survey

The second survey also shows participants are positive about the daily-reflection feature (questions 1 and 1a). They describe the added value more clearly:

> *I reflect on things I learned that day and things that are quite special, which I would not have thought about without the questions.* [Participant 202]

The week reflections remain underused, even though participants say they are interested. Those that have used it appreciate its reflective format (questions 2 and 2a).

> *Especially step 2 in the weekly reflection (the analysis). By asking follow-up questions about the questions from step 1, you really start to think deeply about why you feel a certain way. The questions also make me feel thankful!* [Participant 451]

About half of the participants state they get value from the overview page of their learning goals. The way the other half uses the app is not supported by the app's design (question 4).

> *Personally, I don't pay much attention to the charts, tips, and tops. This is because I mainly use free writing.* [Participant 163]

> *I hadn't really reflected on learning objectives yet; I had mainly written reflections about the days themselves.* [Participant 363]

The second survey shows participants appreciate the incremental, iterative growth of the daily reflection- and learning goal-features. This supports them to be more mindful of their learning process and goals (question 3):

> *This way, I remember much better what I've done, and I often find that I've done more than I think.* [Participant 664]

Posttrial Semistructured Interviews and Coach Focus Group

In total, 13 participants responded to our call for a posttrial interview, 2 of whom had not used the tool but had enrolled for the study at the start. We specifically included nonusers to better understand the perspective of students who had the opportunity to use the app but chose not to engage with it.

Fading App Usage

Nearly all app-using participants remarked that usage faded over time. A commonality among the reasons given was the transition students experienced from an initially challenging environment to one in which they experienced more confidence in their capabilities and were less in need of ways to structure their experiences. This decreasing urgency is mirrored by the decrease of in-app activity as seen in the log data.

Combining students' accounts of this transition with the reflection contents and learning goal categories, we see one distinct usage pattern which affects this (refer to Table 3 for a joint display). The pattern consists of students who used the app predominantly for clinical skill learning goals by logging performed procedures. They describe the transition as moving from a "learner" to a "worker" attitude or "just doing the work."

XSL•FO
RenderX

Table . Joint display showing students' pattern of use compared with their learning goals per category and an illustrative quote of their reason for quitting the app (this table only includes students who were interviewed).

Pattern of use and participant	Learning goals	Illustrative quote for quitting the app
Clinical skill		
246	• CS[a]=2 • IP[b]=2 • SEC[c]=0	"But after a month, I had a pretty good handle on it, and now it's just work, work, work."
269	• CS=6 • IP=1 • SEC=0	"Yes, I've become so ingrained in that department that it no longer feels like I can really learn much more, so to speak."
451	• CS=1 • IP=1 • SEC=0	"Because I was getting more into the flow of work, I was, like, less focused on the school's learning objectives. It became more like work instead of [learning]."
664	• CS=1 • IP=3 • SEC=0	"It's all pretty much the same. (.) I didn't really do much with it, so I noticed, like, that as the internship went on, I'd start thinking, well, should I write something down again this afternoon, or not? Or should I? Or what am I going to do? And then decided I didn't feel like it."
960	• CS=5 • IP=0 • SEC=5	"Well, it's because I'm really focusing on the new part of my internship. That I'm putting a lot of interest and energy into learning what they do there. So then that extra part about how I should work on myself, I kind of disregarded it."
Socioemotional competences or journaling		
163	• CS=0 • IP=1 • SEC=0	"And at some point you think, if it's been two or three days, 'Oh well, that's not fresh in my memory anymore, is it?' I'll just make sure to do it another time. But then, that 'another time' sometimes never came."
363	• CS=0 • IP=2 • SEC=1	Severe technical issue
402	• CS=1 • IP=1 • SEC=1	Severe technical issue
528	• CS=4 • IP=5 • SEC=5	Severe technical issue
Other		
309	• CS=1 • IP=3 • SEC=0	"I quickly had this intuitive sense of how things were going, so I didn't feel like I needed it."
907	• CS=0 • IP=1 • SEC=0	"I don't know, I just didn't manage to find my way around in the app all the time"

[a]CS: clinical skill.

[b]IP: introductory period.

[c]SEC: socioemotional competences.

> *Yes, I don't think about it as much. That's a shame, of course, because you want to keep pushing forward and keep learning. But over the past few weeks, I've noticed that I'm just working along with the team. I'm thinking less about like, what went well and what could go better.* [Participant 451]

XSL•FO
RenderX

For some of these students, this shift in attitude coincided with a sense of having learned all there is to learn for this clinical placement.

> *Well, I'm trying to challenge myself to work in other departments to see something different. But basically, yes, there are so few nursing procedures that when there were a lot, I could set a learning goal for each one. Yes, I've become so ingrained in that department that it no longer feels like I can really learn much more, so to speak.* [Participant 269]

Most students who used the app for SEC learning goals or as a more personal journal of their learning experience quit due to the severe technical issue. For them, the app provided a consistent place for experiencing a sense of growth and peace of mind, and kept them from forgetting their experiences.

> *Yeah, maybe it's a little weird, but like it gives me some peace of mind or something. Because sometimes you're in the middle of an internship day and think to yourself: why am I doing all of this anyway? And when you're busy in the app, for me it brought a sense of, oh, right, I see now, I have been working on this after all, and I have grown a bit. Or at least stayed consistent with it, so it did give me some peace of mind, like, oh, all of this does have a purpose.* [Participant 528]

> *But in the end, it did provide an overview of everything you've learned. Because I think if you didn't use the app or didn't think about it every day, you'd end up trying to remember everything later on. Like, oh yeah, I think I learned this too. But if you really know what you did each day… Because at the end it all just becomes one big blur, so to speak, now you really know a bit about when you learned what.* [Participant 402]

Consequences of Fading App Usage

For all students, no longer using the app meant their conscious learning shifted to unconscious and, for some, more passive learning. The coaches also remarked on this:

> *They learn a lot in the second half, but they are less aware of it because they are also more focused on working.*

Coaches acknowledged the transition being a common occurrence during clinical placement. Coaches mentioned that a low level of detail in a student's plan of approach, written at the start of the clinical placement, often leads to this passive attitude. Other reasons came down to:

1. Whether the working environment fostered students' learning as opposed to treating them as workload-relief
2. The desire of the individual student to continuously develop their SEC, as the first clinical placement's bar is low in that regard
3. Whether students proactively sought opportunities and activities to learn from, as opposed to a more reactive or passive stance.

In line with the coaches' observation, most participants remarked that no longer using the app also resulted in less awareness of their personal and professional growth.

> *Yes, well, that was indeed the case. In the beginning, I used it a lot, and then the halfway evaluation came, and then I noticed that, yes, at least. In the beginning, I had a clear picture, but those last 2, 3, 4 weeks. It was just like I was working. As if it was just normal for me to do certain things. And only then I thought, yes, some things are actually not normal at all for us to already do.* [Participant 163]

Other Avenues for Reflection

The 2 students who had not used the app seemed to already have a structured learning approach: meaningful situations were noted in a physical journal and reflected upon. Additionally, both could identify and act upon relevant "learning moments" during their shift. This indicates that students who can self-regulate their learning might have less need for this app.

Other students shifted their reflective needs to colleagues or peers, depending on the clinical placement's own learning environment. Like the app, colleagues in a learning-inducive environment could provide students with insight into their learning and progress. However, those discussions rarely focused on SEC.

Due to the severe technical issue, some students chose to use our nonapp alternative, albeit only briefly. The main reasons for students to prefer the app came down to (1) a clearer connection between learning goals and daily experiences, (2) a stronger sense of achievement upon seeing their progress in the app, and (3) the ease of use of a predefined format for reflection.

Discussion

Principal Findings

This study explored how and why nursing students used the Nurse-IT reflection app's features to structure their learning process for developing SEC during clinical placement. Using an embedded mixed methods approach and a naturalistic setting, we were able to capture a detailed and realistic picture of how the app was used and how this usage changed during the clinical placement. We will first discuss how students used the app to structure their learning. We then highlight how that pattern of use differed from our intended use and what we can learn from it. Finally, we discuss students' apparent changing needs during clinical placement and what that means for the design of such reflective applications.

Role of the App in Student Learning

The overarching design goal of the app was to stimulate learner agency through scaffolding a self-regulated learning process (Figure 1). We modeled this learning process by defining *learning goals and tasks* (forethought phase), *daily reflections* (monitoring phase), and *weekly reflections* (self-reflection phase and forethought phase). This section discusses how and why parts of this process supported students in structuring their learning process.

XSL•FO
RenderX

Having the app facilitate a self-regulated learning process alleviated students of the burden of setting up such a process themselves. This is seen in how students valued the app for lowering their mental workload. For example, writing experiences down meant no longer having to remember them. Finally, students remarked how the preformatted questions made it easy for them to engage in goal-setting and reflection. These findings underline the importance of applying persuasive systems design principles when designing such tools [34]. Thus, taking away practical barriers makes engaging in self-regulated learning manageable for students.

Structural engagement with the app made students more aware of their learning process (eg, remembering learning goals during a shift). In turn, this awareness helped them identify learning opportunities and connect those to their learning goals. Other studies focusing on supporting reflection in nursing students show similar effects [12,28]. Survey and interview findings show students valued these effects the most. Overall, this highlights that structurally making one's learning explicit enables students to act on it.

Moreover, and in line with other studies, students who structurally used the app also remarked how its various overviews helped them see and appreciate their growth [12,35]. This boosted confidence and motivated app usage. This effect was best seen in students who used the app as a reflective journal or to capture and evaluate experiences in relation to SEC-related learning goals. In contrast, students who only recorded clinical procedures appreciated their development, but noted it became repetitive and questioned its long-term value. Thus, making one's learning explicit also motivates further action, especially when it is focused on SEC-related learning.

Arguably, this could be achieved through more affordable, physical notebooks. However, students who switched to our nonapp alternative said they missed how the app structured their learning process. For example, the link between learning goals, tasks, and daily reflections, and how the app summarized their growth. As a result, they stopped using the alternative, further underlining the benefits of smartphone-based support systems [29-31]. Thus, empowering students to have an overview and awareness of their learning process scaffolds a self-regulated learning process.

Discrepancy Between Intended Use and Actual Use of the App

Overview

Our intended learning process included all features of the app. However, most students only used the learning goals (forethought phase) and daily reflections (monitoring phase). The weekly reflections were only used sporadically. Given the beneficial effects discussed in the previous section, this raises questions about the necessity of our intended learning process and the potential consequences of how students used the app. We will first discuss the assumptions behind our weekly reflection's design, then relate those to the students' favored pattern of use, the consequences of that use, and its implications for designing reflection apps for clinical placement in nursing programs.

Weekly Reflection Design Assumptions

We designed the daily reflection format to get to surface-level insights, with weekly reflections providing deeper reflection. Thus, although the daily reflections have some self-judgment (a part of the self-reflection phase), we believed the weekly reflections would be necessary for self-reflection.

Aside from depth of reflection, the weekly reflections also dictate a pace for the self-regulated learning cycle. Even though this was not technically enforced within the app, the term "weekly" indicates a pattern.

Finally, the weekly reflections consist of 2 steps—a guided reflection on an experience of the past week (self-reflection phase) and a check-up on one's goals to prepare for the following week (forethought phase). With the latter, the weekly reflections represent the start of a new self-regulated learning cycle. Thus, we assumed students needed scaffolding for reviewing their goals, completing them, and setting new ones.

Students' Pattern of Use and Its Consequences

A key aspect of how students used the app differently lies in how they approached their learning goals. Whereas we intended students to complete them and set new ones, the majority of students only set them at the start. Moreover, no one completed a learning goal. Instead, students set large learning goals, which they worked on throughout clinical placement. This negatively impacted the weekly reflections' relevance.

Consequently, students' self-regulated learning cycle took on a different form: students used the app to monitor their progress on these large goals. Their self-reflection and forethought phases aligned closely with the daily reflections' features: how they are performing (eg, grade and top-field) and whether they need to adjust their approach (eg, tip-field and free writing). Additionally, the interview findings show self-regulated learning also took place *outside* the app (eg, reflecting with colleagues or peers). Overall, this indicates the weekly reflection was not needed for self-regulated learning.

This pattern of use had 2 consequences. First, students with few goals who did not set new goals were prone to quit the app and transition to a working attitude. For these students, only using daily reflections hindered their self-regulated learning. Second, without structural moments of deeper reflection, students potentially stay stuck in superficial learning, ultimately not reaching their learning goals [37].

Lessons for Designing Reflection Apps for Use in Clinical Placement Learning

The key finding in this unintended pattern of use is that supporting students through the self-regulated learning phases does not require in-app, phase-specific activities. In our case, supporting students in remembering and monitoring their learning goals seemed to already enable self-regulated learning. This highlights that students can go through these phases *outside* of the app, and that self-regulated learning is not a strictly linear process [43,44]. It is unsurprising that, given the nature of clinical placement learning, learning cannot be completely scripted. Thus, a reflection app for clinical placement learning

XSL•FO
RenderX

should focus on enabling self-regulated learning and avoid a rigid process of in-app activities.

When it comes to enabling self-regulated learning, our findings show the importance of removing practical barriers. One barrier was forgetfulness. Students wanted reminders for their daily reflections, with some quitting the app after a period of inactivity. Similarly, students could be reminded to review their goals to maintain an intentional learning attitude. Thus, the intensive nature of clinical placement requires reflection apps to reduce the cognitive load of managing one's learning process.

Another barrier ties to our weekly reflection—ease of access. Students who did write weekly reflections found them to be useful but lacked triggers to reflect more often. Those who did not use them were interested yet lacked a trigger to try them. One could address this by facilitating students to write deeper reflections when they realize they want to during the daily reflection. One unimplemented feature was to have the free writing field be interchangeable with reflection frameworks (eg, ALACT by Korthagen et al [45]). Future research into such features is needed to understand how a reflection app can facilitate students' shifting reflection needs.

Students' Changing Needs Throughout Clinical Placement

A final key finding was the decline in app use, with nearly all students no longer using the app after the halfway point (10 wk). Interestingly, other studies with similar app interventions do not report this decline in use while having similar, mostly positive experiences.

One reason could be that those studies featured shorter clinical placement periods, such as 3 weeks [27,28], 6 weeks [20,46,47], or 8 weeks [12]. Yet, some studies that spanned a similar period of time do not report a decline in use [13,31]. From what we can tell, the difference there lies in whether using the tool was a required part of clinical placement learning. Shajani et al [13] digitized an existing, required reflection exercise, and Slade and Downer [31] measured students' perceptions of electronic portfolios already being used in a curriculum. Thus, one reason for our dropout rate could be that it was optional to use.

Looking at the interview and focus group findings, we believe the decline is partially due to students experiencing a transitional phase during clinical placement. Students valued the structure provided by the app in the *initial, tumultuous phase*. Students' reflections and goals reflect this as they focused mostly on learning protocols, how the team operates, and building rapport with patients. Similarly, this is when they learned clinical skills through hands-on experience. Thus, the urgency of the learning goals was high—"I need to function within the team!"—and one's day-to-day growth was more palpable—"I am doing things I could not do last week!"

As this phase ended, *how* students used the app influenced further use. Students whose learning goals focused on clinical skills lacked urgency to further monitor their progress and quit the app. These students often did not manage their learning goals, whereas students with a large set of goals or who used a journaling approach stayed active longer. This indicates certain types of use are more conducive to self-regulated learning and should be advised.

Study coaches remarked that it is harder to get students to critically reflect on their learning process in the second half of the clinical placement. This is seen in how students lost awareness of their learning process and stopped reflecting after app use faded. Moreover, some students missed the oversight and, in hindsight, felt like they would have benefited from further use. This indicates that the work-oriented attitude and its unintentional learning process can hinder self-regulated learning.

The interviewees described clinical placement as being more conducive to learning the starting-phase skills. Most colleagues were willing and capable of helping students reach these goals, for example, through modeling procedures, giving clinical feedback, or explaining protocols. Contrastingly, and in line with other research [15,17], SEC—such as giving feedback or conflict management—were harder to discuss and thus found less uptake by students. Additionally, such skills bear less urgency and are more abstract than, for example, learning a new procedure. Thus, clinical placement as a learning environment and the nature of learning SEC within such an environment also influenced whether students were able to use it for that purpose.

Given the above finding, we believe other intervention components are needed to prepare students for practicing SEC during clinical placement. The app's goal-setting and reflective structure then enables further learner agency and self-regulated learning of SEC. For example, only the few students in our field trial with clear goals regarding SEC managed to work on them. The study coaches acknowledged this, saying students who start with clearer goals are more likely to maintain a learning attitude. Simulation learning could help prepare students to practice with SEC before clinical placement [3,19,48,49]. Subsequently, SEC becomes more recognizable and their urgency clearer, enabling students to set concrete goals and tasks.

Overall, the app's structure fulfills students' early clinical placement learning needs. However, the app's current design and how it was introduced to students do not support the more intentional approach needed for prolonged use. Looking at a recent similar study [12], we believe a stronger integration with the coaching process could help stimulate a more intentional approach (eg, revising or setting new learning goals). Thus, the design and implementation of a reflection app like ours needs to consider these changing needs to reach its intervention goals.

Limitations

Two data collection issues occurred during the field trial. First, we observed low response rates to our first survey. Students struggled to keep up with our intended pace for surveys, as they were overwhelmed by the first weeks of clinical placement. Moreover, the surveys were the only part of the field trial that did not benefit their own learning process. We took two measures to address the low response rates:

1. Financial compensation: Students would receive a gift coupon of €10 (US $11.40) if they filled in at least 2 of the 3 surveys. Although this could introduce response bias, we aimed to mitigate this by framing the incentive as fair

XSL•FO
RenderX

compensation for their time spent on the surveys. Additionally, research shows incentives to be an effective tool to increase response rates with no clear indication of lower response quality [50].

2. More time between surveys: We slowed down the pace of surveys to allow students more time to fill them in.

The second issue was technical and required us to stop the trial in the 13th week. As a result, we could not send out the third qualitative survey nor gather further log data. At that time, there were only 2 active users left, meaning comparatively little log data were lost. Similarly, the third survey would have had a low response rate. Nevertheless, the technical issues did bar us from measuring how students used the reflections to prepare for their clinical placement assessment, a question which could be addressed in future research.

The open setup of the study made it harder for us to evaluate our intended reflective process. We did explain the idea behind the types of reflection and the self-regulated learning cycle as a potential way to use the app. However, we did not require this pattern of use due to the exploratory nature of the study; we were interested in how they themselves would use it. Thus, although our approach led to insights in the variety of ways students used the app in their learning process, our study lacked insight into the potential effect of our intended reflective process.

Similarly, the small sample size, lack of a control group, and design of our study limited our capability to measure the effect of the app on student learning and SEC development. Nevertheless, this means our findings should be interpreted with caution and for their descriptive value of students' experiences with the app and its role in their learning process. Future experimental research should look into the effect of reflection apps on SEC development during clinical placement. Finally, our small sample size and focus on one specific clinical placement in one specific nursing program limit the generalizability of our findings. We addressed this inherent limitation by supporting transferability of our findings to different contexts. For example, transparency in the design of the app and its underlying guidelines helps other researchers understand the intent behind design choices and gives context to our findings. Similarly, the mixed methods approach provides a rich description of the context, which further supports other researchers' understanding of the relevance of our findings to their context. In doing so, we aim to support future research on this topic.

Conclusions and Implications for Practice

The study's exploratory and naturalistic nature allowed us to follow students' developments throughout the clinical placement and the role of the app within it. The findings show that supporting students in structuring and monitoring their clinical placement learning helps them during the initial phase of the clinical placement. Although limited, our study indicates that capturing experiences as opposed to logging clinical procedures is key in using reflection for SEC development purposes. Concurrently, we see that the social norms of the workplace impact students' SEC development, indicating interventions should address this in their design.

Future research should investigate how educational interventions can adapt to students' changing attitudes toward learning as the clinical placement progresses. Additionally, for SEC development specifically, research into multicomponent intervention designs is needed to help students practice these competencies during clinical placement. Our findings can inform designers and nursing educators of the complexities in designing for nursing students' SEC development during clinical placement.

Acknowledgments

We are grateful to Ms Mirjam Palsma for her assistance with the recruitment phase and for allowing the field trial to be conducted during her course. No generative AI was used during the creation of this manuscript.

Funding

Abstract

Background: The integration of digital health technologies (DHTs) in clinical practice is accelerating, creating a need for nursing students to develop digital competencies aligned with professional expectations. In Quebec, curricular reforms aim to enhance digital health literacy, but data are limited on students' preparedness.

Objective: This study aimed to assess nursing students' perceptions, self-reported competencies, and willingness to engage with DHTs across different academic years.

Methods: A cross-sectional descriptive survey assessing self-reported digital health competencies, attitudes, perceived training coverage, and intentions was conducted using an online questionnaire administered through Qualtrics. Participants (N=136) were recruited from 3 cohorts: first-year (group 1; n=58, 42.6%), second-year (group 2; n=55, 40.4%), and third-year (group 3; n=23, 16.9%) nursing students. Data were analyzed using descriptive statistics and ANOVAs, with post hoc analyses performed via SPSS.

Results: Significant differences were observed among cohorts concerning digital competencies and access to digital tools. Compared with first-year students (group 1), third-year students (group 3) showed higher proficiency with electronic medical records (group 3: mean 3.29, SD 1.31; group 1: mean 2.59, SD 1.32; P=.01), virtual reality (group 3: mean 4.53, SD 1.11; group 1: mean 2.90, SD 1.44; P<.001), and clinical databases (group 3: mean 4.59, SD 1.00; group 1: mean 3.21, SD 1.55; P<.001). Despite positive attitudes toward DHTs across all groups, training coverage for most digital tools was perceived as low, with the highest levels reported for clinical databases (mean 2.97, SD 1.1). This underscored a substantial gap between institutional expectations and actual digital training across all cohorts.

Conclusions: This study highlights critical gaps in digital health training among nursing students, emphasizing the need for targeted curricular reforms such as the one currently underway at the Université de Montréal. These efforts represent a promising opportunity to better align educational content with the evolving demands of health care systems. Today, preparing students in digital competencies is no longer just advantageous but may soon become essential for the next generation of nurses to navigate and lead within technology-driven care environments.

Introduction

Macro-Level Context: Digital Shift in Health Care

The digital transformation of health care systems is rapidly redefining how care is delivered, documented, and managed worldwide. Across clinical environments, digital health technologies (DHTs)—including electronic medical records (EMRs), virtual care platforms, and artificial intelligence—are increasingly deployed to enhance care coordination, improve efficiency, and respond to growing service demands [1,2]. In

XSL•FO
RenderX

Quebec, this shift is occurring amid a persistent nursing shortage that places additional pressure on health care institutions and personnel [3]. Strategic investments in digital infrastructure, such as those outlined in the province's 2022 to 2025 technological modernization plan and the federal Pan-Canadian Health Data Strategy, have positioned digital tools as key enablers of more responsive, equitable, and sustainable care delivery [4,5].

Professional Standards and Competencies

To ensure that nurses are prepared to operate within these digitized environments, regulatory and educational bodies have issued guidelines calling for the integration of informatics into nursing practice. The Ordre des infirmières et infirmiers du Québec (OIIQ) emphasizes the importance of digital competencies for safe, ethical, and efficient care across both in-person and virtual settings [6,7]. At the national level, the Canadian Association of Schools of Nursing (CASN) has updated its National Nursing Education Framework to include explicit expectations for digital health literacy among nursing graduates [8]. Together, these standards promote the incorporation of information and communications technologies into nursing curricula as both a professional requirement and a pedagogical priority.

Educational Challenges in Nursing Programs

Despite these mandates, gaps remain in the actual delivery of digital health training across Canadian nursing programs. While students often demonstrate general digital literacy, studies show that they are underprepared to use clinical information systems, navigate electronic records, or interpret data generated by digital tools in real-world practice [9-11]. Furthermore, many programs offer inconsistent or superficial exposure to health ITs (HITs), contributing to low confidence and proficiency among graduates [11]. These limitations risk widening the gap between institutional expectations and actual clinical readiness, particularly as the pace of digitalization continues to accelerate. Previous studies indicate that, although nursing students tend to have a positive attitude toward digital health, their clinical readiness remains limited due to inconsistent exposure to health information systems. Competency frameworks such as those from the CASN and OIIQ underscore the need for structured, progressive integration of digital training into nursing education [7,8]. These limitations contribute to low confidence and perceived readiness among graduates entering technology-rich clinical environments.

Study Rationale in the Quebec Context

Although several studies have examined nurses' perceptions of digital health tools, few have focused on nursing students in Quebec, where the educational structure, regulatory environment, and pace of curricular reform differ from those of other Canadian provinces [12]. Given recent efforts at the Université de Montréal (UdeM) to revise its undergraduate nursing program to better align with CASN and OIIQ guidelines, it is crucial to understand students' current perceptions, competencies, and intentions regarding DHTs. To our knowledge, this is the first study in Quebec to use a cohort-comparative design to examine digital health preparedness among nursing students. Grounded in the technology acceptance model and the OIIQ digital competency framework, this study aimed to identify year-based differences in perceptions and training gaps, thereby informing targeted curricular reforms to support Quebec's digital health transformation [12,13].

This study was conceptually inspired by the behavioral framework by Paré et al [14] examining medical students' intention to integrate DHTs, which combines elements from the theory of interpersonal behavior by Triandis [15] and the technology acceptance model [16]. The survey content was further adapted to the nursing context using insights from the 2020 National Survey of Canadian Nurses on the use and impact of DHTs in practice. The final instrument was reviewed and validated in collaboration with experienced nursing professors from the Faculty of Nursing (Faculté des sciences infirmières in French; FSI) at UdeM to ensure relevance and clarity for nursing students.

Research Objectives

This study had the following objectives:

- Explore the perceptions and intentions of nursing students regarding their knowledge, experiences, and training related to HITs and their beliefs, attitudes, and intentions concerning the use of HITs in their future professional practice
- Compare these perceptions and competencies based on students' year of study to identify potential differences across cohorts
- Provide recommendations for improving HIT-related education in response to the identified needs

Methods

Design, Setting, and Participants

This study used a cross-sectional descriptive design. It was conducted at the FSI at UdeM in May 2023. The target population included 1274 students enrolled in the FSI at UdeM. A target sample size of 300 was chosen based on recommended minimum thresholds for descriptive surveys in large student populations [17] to ensure reasonable representation as no formal power calculation was required for this exploratory design. Eligible participants were all students currently enrolled in an undergraduate nursing program who provided informed consent.

It is important to note that participant distribution across academic years was uneven. This reflects actual enrollment sizes within the program during the data collection period.

Ethical Considerations

This study was reviewed and approved by UdeM's Research Ethics Committee in Sciences and Health (2023-4300) and was supported by the FSI. All participants provided informed consent electronically before starting the survey and could withdraw at any time without consequence. Data were collected anonymously to ensure participant privacy and confidentiality. No financial or other compensation was provided for participation.

XSL•FO
RenderX

Recruitment

UdeM was selected as the research site due to its status as a major higher education institution in Quebec and the diversity of its undergraduate nursing student population. Recruitment was conducted electronically through the FSI, which emailed an initial invitation and one reminder to all eligible students via their institutional addresses. Interested participants accessed the study by clicking a secure link leading to the consent form and the online questionnaire. Participation was voluntary and anonymous. Although IP addresses were not collected to ensure confidentiality, the use of institutional email distribution and limited reminders minimized the risk of multiple entries.

Data Collection

Data were collected through an online self-administered questionnaire designed specifically for this study administered via Qualtrics (Qualtrics International Inc), a platform designed for web-based research that offers basic descriptive statistics tools while ensuring secure data handling.

The questionnaire took approximately 15 minutes to complete and included an open-ended question at the end, allowing participants to share additional comments. Although this open-ended question was included at the end of the questionnaire to capture additional student perspectives, these responses were not systematically analyzed in this study. An exploratory review of these responses was conducted to inductively identify recurring themes and enrich the interpretation of the quantitative findings by reflecting participants' lived experiences and unprompted perspectives.

The survey was developed to operationalize key constructs from the conceptual framework described above. Specific items were adapted from the study by Paré et al [14] and the 2020 National Survey of Canadian Nurses to align with the nursing context and relevant DHTs. The draft instrument was then reviewed and refined in collaboration with experienced nursing faculty at UdeM to ensure content validity and clarity. The final version included 15 items (Table S1 in Multimedia Appendix 1) and is available in Multimedia Appendix 2.

Variables

This study assessed nursing students' perceptions, competencies, and training needs related to HITs across 4 main categories of variables.

Sociodemographic and Academic Variables

Sociodemographic and academic variables included the year and type of academic program; the participants' age, sex, and gender; languages of interaction; daily use of digital devices; previous professional experience in the health care sector; and current or intended professional setting after graduation.

HIT Competencies and Training

Using Likert-type scales, participants assessed their level of proficiency with various technologies (1="none," 2="very low," 3="low," 4="moderate," 5="high," and 6="very high"), the extent to which HITs were covered in their nursing education program (1="not covered at all," 2="poorly covered," 3="moderately covered," 4="well covered," and 5="very well covered"), and the level of expertise they believed was necessary for clinical practice (1="no training needed," 2="basic training," 3="functional or intermediate training," and 4="expert or specialized training).

Perceived Impacts of HITs

Participants were asked to rate the perceived impact of DHTs on key aspects of the nursing profession, such as quality of care and work life. The question was phrased as follows: "Do you believe that the use of digital health technologies has, or will have, an impact on the following dimensions of the nursing profession?" Responses were collected on a Likert scale (1="very negative impact," 2="negative impact," 3="neutral impact," 4="positive impact," and 5="very positive impact"). An open-ended question followed, allowing respondents to elaborate or provide additional comments.

Statistical Analysis

Students were grouped into 3 categories based on their year of study: first year of the integrated diploma of college studies–bachelor's degree (*diplôme d'études collégiales–baccalauréat* in French; DEC-BAC) and regular bachelor's degree (*baccalauréat* in French; BAC) programs (group 1), second year of the DEC-BAC and BAC programs (group 2), and third year of the DEC-BAC and BAC programs (group 3). All Likert scale variables were treated as continuous variables and analyzed using means and SDs.

For categorical variables, frequencies and percentages were reported for each group as well as for the total sample. Group comparisons were conducted using exact *P* values from chi-square tests. For continuous variables, valid sample sizes, means, and SDs were presented. Group means for Likert scale variables were compared using one-way ANOVA followed by Tukey post hoc tests where appropriate.

An exception was made for the variable "training coverage—scheduling software," where the Welch correction for unequal variances was applied and post hoc comparisons were conducted using Games-Howell tests. All statistical analyses were performed using the SPSS software (version 28; IBM Corp), with a significance level set at 5%.

Results

Sociodemographic and Academic Variables

Overview

A total of 173 students accessed the questionnaire. The response rate for the item identifying participants' academic year within the nursing program was 78.6% (136/173). After grouping, group 1 comprised 42.6% (58/136) first-year students, group 2 comprised 40.4% (55/136) second-year students, and group 3 comprised 16.9% (23/136) third-year students.

Participant Profile

Across all groups, more than 67% (92/136) of participants were aged between 18 and 25 years, with group 3 standing out at 80% (19/23) in this age range (*P*=.03). This group also reported significantly higher access to a laptop (*P*=.02). Use of digital tools for specific activities was also significantly greater among

XSL•FO
RenderX

groups 2 and 3 (*P*=.01). Additionally, a higher proportion of group 3 participants reported working in the provincial public health care sector (*P*=.003; Table S2 in Multimedia Appendix 1).

HIT Competencies and Training

HIT Proficiency Levels

Proficiency levels across all work-related HITs were generally rated from low to moderate. Group 2 stood out in terms of proficiency with EMRs (*P*=.01), whereas group 3 demonstrated higher proficiency with virtual reality (*P*=.001) and clinical databases (*P*=.001; Table S3 in Multimedia Appendix 1).

Training Coverage by Group

Regardless of the specific HIT in question, coverage within the curriculum was generally perceived as very limited to minimal. Group 1 reported greater coverage in the use of scheduling software (*P*=.007), whereas group 3 reported more extensive coverage in database training (*P*=.004; Table S4 in Multimedia Appendix 1).

Required Expertise for Professional Use of HITs

Participants generally believed that most HITs required little to no specific expertise for professional use. An exception was noted for group 2, which reported a significantly higher need for basic or intermediate training in the use of health care robots (*P*=.02; Table S5 in Multimedia Appendix 1).

Perceived Impacts of HITs in the Nursing Profession

Perceptions of the impact of HITs on the nursing profession were consistent across all groups. Most students believed that DHTs have a positive or very positive impact on key aspects such as quality of care, therapeutic relationships, and productivity (Table S6 in Multimedia Appendix 1).

Narrative Comments

Of the 136 respondents, 31 (22.8%) provided written responses to the open-ended question. Most comments reflected key patterns observed in the quantitative results, particularly regarding the perceived lack of formal training in DHTs. Several students reported learning to use digital tools only during clinical placements, consistent with the limited curriculum coverage ratings found across cohorts. One respondent noted that "[w]e only learn to use digital tools during internships," whereas another remarked that "[a]t university, we have no training on the software we encounter in practice."

Others described barriers to accessing technologies during clinical placements due to their student status:

> *As a nurse it's fine, but as a student, it's complicated when we don't have the access.*

These comments aligned with cohort-based differences observed in digital tool use and confidence levels.

However, the responses also surfaced dimensions not captured in the structured survey. Several participants mentioned psychosocial or physical impacts of digital tool use, including "less sleep, eye strain, and a more sedentary lifestyle" and "technology sometimes limits social interaction, which affects mental health." A few students proposed improvements, such as earlier exposure to clinical systems or greater consistency in tools across health care settings:

> *It would help to learn some of the clinical software in advance.*
>
> *Please standardize the digital documents, it would simplify things when moving between institutions.*

While broadly aligned with the quantitative trends, these narrative comments introduced experiential nuances, such as well-being, autonomy, and implementation barriers, that were not accessible through the Likert scale items alone.

Discussion

Principal Findings

Both the OIIQ Comité jeunesse and the OIIQ [6,12] emphasize the importance of access to IT that supports nurses' clinical decision-making, optimizes care processes, and enhances patient safety, as well as maintaining professional and ethical standards.

Similarly, the CASN, through its National Nursing Education Framework [8], underscores the importance of integrating nursing informatics competencies into academic programs to better prepare future professionals for the increasing technological demands of clinical environments.

However, our findings indicate that students perceive their current training as insufficient. Their self-assessed proficiency with digital tools was limited, and coverage of key HITs was generally perceived as weak without a clear progression across academic years despite students showing an interest in these tools and their potential impact on nursing practice.

These observations suggest a concerning disconnect between the evolving expectations of the health care system and students' perceived preparedness despite the clear guidelines set forth by both the OIIQ and CASN. This aligns with findings by Kleib et al [11], who identified persistent gaps in digital health education that were exacerbated by pedagogical approaches that often overestimate students' technological competencies and fail to adequately prepare them for clinical realities.

The narrative comments reinforced this disconnect by providing concrete examples of students' perceived lack of preparation, particularly in relation to clinical software. The comments also highlighted barriers that were not captured in the structured survey, such as restricted access to digital tools during placements and the personal toll of technology use on well-being. These experiential accounts complement the quantitative findings and emphasize that perceived readiness is shaped not only by curricular content but also by the conditions of access, support, and emotional experience within clinical environments.

The fact that many participants in our study believed that high-level proficiency was unnecessary for the effective use of HITs may reflect a limited understanding of their relevance in nursing practice. Kleib et al [11] emphasize that, while students often demonstrate basic digital literacy, this does not necessarily translate into clinical competence. Consequently, students may

XSL•FO
RenderX

underestimate the complexity and significance of digital tools in real-world settings. These findings highlight the pivotal role of nursing educators in bridging this gap by explicitly integrating digital competencies into nursing curricula and grounding them within authentic clinical contexts to foster both awareness and applied proficiency.

Despite these challenges, the surveyed students remained generally optimistic about the role of HITs, with most believing that these technologies will have a positive or even very positive impact on the nursing profession. This optimism reflects a growing awareness of the digital shift in health care and aligns with the strategic directions promoted by the OIIQ and CASN, who advocate for stronger digital health training in nursing education [7,8].

Beyond these overarching findings, notable differences emerged between academic years in terms of access to digital tools, proficiency with specific technologies, and perceived curriculum coverage. This study identified several statistically significant differences in how students from each cohort perceived and interacted with HITs.

The 18- to 25-year age group predominated across all cohorts, particularly in group 3, where it represented 83% (19/23) of the participants. Group 3 students also reported greater access to digital tools, especially laptops, and more advanced use of EMRs, virtual reality, and databases. These findings are consistent with the broader and more in-depth training coverage that this group reported for these tools.

The observed differences in competencies and training exposure likely reflect curricular progression, with third-year students benefiting from more extensive clinical placements, capstone projects, and practical assignments that integrate digital tools. In addition, group 3 students may have greater opportunities for independent learning and part-time work in health care settings, reinforcing their proficiency with EMRs and clinical databases. In contrast, group 1 students are typically at the beginning of their program, focused on foundational theoretical content with limited hands-on exposure to applied digital health systems.

Group 2 students stood out for their more frequent use of digital tools and a higher reported need for advanced competencies in health care robotics. Meanwhile, group 1 students reported better coverage related to scheduling software, likely reflecting academic needs specific to first-year studies.

Taken together, these findings reveal a persistent and concerning gap between current digital health needs and the perceived preparedness of nursing students, echoing the concerns expressed by the OIIQ [7]. They underscore the importance of continuing efforts to integrate digital health competencies into nursing education in a structured and strategic manner.

Limitations and Future Research

Methodological and Contextual Limitations

Of the 1274 targeted students, 136 (10.7%) completed the questionnaire, representing 45.3% (136/300) of the sample size required to ensure statistical representation. While the target of 300 respondents was chosen based on practical guidelines for descriptive surveys, the absence of a formal power calculation means that the study may be underpowered to detect smaller effect sizes or subtle group differences, particularly given the uneven distribution across cohorts.

The unequal sample sizes between academic years may also have limited the statistical power for some comparisons. However, this limitation mirrors real enrollment patterns and was accounted for using appropriate statistical analyses.

Although no data were available to confirm a nonresponse bias, the relatively low participation rate raises the possibility of such a risk. Therefore, it is possible that respondents had characteristics or perceptions that differed from those of nonrespondents, potentially limiting the generalizability of the findings.

Additionally, the self-administered nature of the questionnaire introduces the possibility of self-selection and self-assessment bias. Students who chose to participate may have been more comfortable with technology or more aware of digital health issues, potentially skewing responses toward more favorable or more critical perceptions than would be typical. Moreover, as the study was conducted at a single institution, UdeM, the transferability of the findings to other educational, institutional, or cultural contexts is limited. The uneven distribution of participants across groups, particularly the low number of participants in group 3, further reduces the robustness of statistical comparisons and may have hindered the detection of significant effects in certain analyses.

In addition, while this study included an open-ended question that generated valuable narrative insights, these data were reviewed only through an exploratory, unsystematic process and were not coded or analyzed using a formal qualitative methodology. As such, they cannot be considered representative or exhaustive. Even so, the added value of these responses, particularly in revealing experiential and emotional dimensions absent from the structured survey, suggests that future research would benefit from an intentionally designed mixed methods approach. Incorporating qualitative inquiry from the outset guided by a clear theoretical framework would allow for a more comprehensive understanding of how nursing students engage with digital technologies across educational and clinical contexts.

Future Research Directions

The FSI at UdeM is currently in the process of implementing a revised version of its undergraduate program in response to recent recommendations from the CASN that emphasize the importance of developing digital competencies aligned with current clinical demands and realities.

In this context, a pretest-posttest design with independent cohorts comparing students who completed the old curriculum with those trained under the revised program would offer valuable insights into the impact of the reform on digital health literacy, integration, and appropriation. Additionally, consultations with key stakeholders within the faculty, including teaching staff, program directors, educational advisors, and student representatives from each cohort, could provide critical institutional perspectives on the validity of the findings

XSL•FO
RenderX

presented in this study. As part of a complementary qualitative component, this triangulated approach would not only contextualize the results but also help assess how curriculum reform may influence digital health teaching practices.

Several additional methodological avenues could be explored to build on this work and deepen understanding of students' perceptions and competencies regarding HITs. First, replicating the study across multiple nursing schools through a multisite comparative design would help assess the transferability of findings beyond the UdeM context. Second, adopting a mixed methods approach to combine quantitative questionnaires with qualitative interviews could yield a more nuanced understanding of student expectations, perceived barriers, and enabling conditions for meaningful engagement with digital tools. Finally, longitudinal studies conducted throughout the academic journey would allow for documentation of digital competency development over time in relation to different education milestones and ongoing curricular adjustments.

Conclusions, Implications, and Recommendations

This study reveals a significant gap between institutional expectations and perceptions of digital health training by nursing students, particularly in their proficiency with essential tools such as EMRs and clinical databases. Despite recognizing the value of digital technologies, students reported limited curricular coverage and confidence in using them.

These findings call for targeted reforms in nursing education, including the integration of hands-on training, digital simulations, and interactive modules. To address these gaps more concretely, nursing programs could implement several specific measures: (1) dedicated simulation laboratories focused on EMRs and clinical software; (2) mandatory digital health literacy modules that introduce students to national and provincial informatics frameworks; and (3) interprofessional digital health workshops that mirror real-world collaborative settings involving nurses, physicians, and allied health professionals. These recommendations are further supported by students' own accounts, which reflect both a desire for earlier, more practical exposure to digital tools and a recognition of the limitations in their current training environment.

The current curriculum revision at UdeM offers a timely opportunity to evaluate the implementation outcomes of such changes. Future studies using a clearly defined pretest-posttest design, with precise cohort tracking to distinguish students enrolled before, during, or after curriculum reforms and collecting detailed data on external exposure to HITs (eg, work settings) could help assess the true impact of these reforms.

Broader research across institutions and through mixed methods or longitudinal approaches will be crucial to strengthening the evidence base literature. In an increasingly technology-driven health care landscape, equipping the next generation of nurses with robust digital competencies is no longer optional and has become a professional imperative.

Acknowledgments

The authors thank the Statistical Consulting Service at the University of Montreal for their assistance with the study design and data analysis. They also appreciate the support of the Faculty of Nursing in coordinating the project and facilitating participant recruitment. During the preparation of this manuscript, GPT-4o, a generative artificial intelligence (AI) language model developed by OpenAI, was used via the ChatGPT interface to assist with translation, linguistic revision, structural refinement, and clarity enhancement. The authors also used ChatGPT to support narrative refinement and thematic clarity during manuscript preparation, consistent with emerging evidence on the constructive role of generative AI in academic meaning making and reflective synthesis [18]. All outputs generated through AI were carefully reviewed, edited, and approved by professionals and the authors to ensure accuracy, appropriateness, and alignment with the responsible use of generative AI in academic writing [19]. The final version of the manuscript was then reviewed by a professional proofreader to ensure clarity and consistency.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sector.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to privacy and institutional restrictions but are available from the corresponding author on reasonable request.

Authors' Contributions

AC conceptualized the study and led project administration. AC and GP developed the methodology and supervised the study. SH-D curated the data and performed the formal analysis. FAES conducted validation. AC and SH-D wrote the original draft of the manuscript. All authors (AC, SH-D, GP, and FAES) reviewed and edited the manuscript and approved the final version.

Conflicts of Interest

AC serves as an associate editor for the *Journal of Medical Internet Research*. The other authors declare no conflicts of interest.

Abstract

Background: The integration of digital health technologies into nursing education in Saudi Arabia requires reliable tools to assess nursing informatics competency and digital technology self-efficacy among students.

Objective: This study aimed to evaluate the reliability and validity of the Canadian Nursing Informatics Competency Assessment Scale (C-NICAS) and Digital Technology Self-Efficacy (DT-SE) scale among undergraduate nursing students at a Saudi university.

Methods: A descriptive cross-sectional survey of 243 undergraduate nursing students at the University of Ha'il was conducted using the C-NICAS and DT-SE. Internal consistency was examined using Cronbach α, and construct validity was assessed using exploratory and confirmatory factor analyses.

Results: A total of 243 students participated (mean C-NICAS score 54.0, SD 16.9; mean DT-SE score 2.7, SD 0.56). Both scales showed good internal consistency (C-NICAS total α=0.90; DT-SE α=0.80). C-NICAS demonstrated a multidimensional factor structure with an acceptable model fit (comparative fit index=1.00; root mean square error of approximation=0.081), whereas DT-SE showed a 3-factor structure with a suboptimal confirmatory model fit (comparative fit index=0.76, root mean square error of approximation=0.146).

Conclusions: The C-NICAS and the DT-SE are suitable for assessing informatics competency and digital self-efficacy among undergraduate nursing students at this institution, although further refinement of the DT-SE may improve model fit. These validated tools can inform curriculum reform at this and similar institutions in Saudi Arabia and support the digital health goals of Saudi Vision 2030.

KEYWORDS

nursing informatics competency; digital self-efficacy; nursing students; Saudi Vision 2030; health care digital transformation

Introduction

Health care providers worldwide are urgently challenged to integrate digital health technologies into their practices, requiring them to acquire new competencies, especially nurses, the largest single profession in health care systems [1,2]. Electronic health records (EHRs), decision support systems, and mobile health apps are increasingly used to provide safe, efficient, and patient-centered care [3]. Informatics competencies are essential professional requirements for all practicing nurses

XSL•FO
RenderX

today and have been established through international initiatives, including the Technology Informatics Guiding Education Reform (TIGER) initiative. TIGER seeks to prepare new nursing graduates to be digitally literate to enhance evidence-based practice and collaboration among health care disciplines [4]. Additionally, the International Medical Informatics Association (IMIA) has published global educational recommendations that define core biomedical and health informatics competencies and provide a framework for designing and accrediting health and nursing informatics curricula across different professional roles and levels of specialization [5,6]. In parallel, the World Health Organization's *Global Strategy on Digital Health 2020–2025* [7] emphasizes that strengthening the digital competencies of the health workforce, including nurses, through pre-service and in-service education is a key component of achieving safe, effective, and equitable digital health implementation. The World Health Organization guidance on digital education further highlights that integrating digital health content and e-learning into health professional curricula is essential for building workforce capacity and supporting lifelong learning in rapidly evolving digital health systems [8].

Saudi Vision 2030 represents Saudi Arabia's national vision for economic development and social reform, with a focus on digital transformation and the adoption of eHealth as a mechanism to cultivate a modernized and technologically prepared workforce to address future digital challenges in health care [9]. Investments in national EHR and health information systems demonstrate this commitment to digital transformation [10]. Although significant progress has been made toward achieving the digital transformation of health care services in Saudi Arabia, barriers continue to exist among nursing students; newly graduated nurses from Saudi Arabia continue to indicate that they possess modest levels of informatics competency and low confidence in their ability to apply digital technology in both academic and clinical settings [2,11]. The results of these studies clearly illustrate an important disconnect between the national goal of a fully developed digital health care system and the preparedness of the future nursing workforce to deliver services in this system [12].

Several international studies support the use of the Canadian Nursing Informatics Competency Assessment Scale (C-NICAS) in both high- and low-income countries. Internationally, studies validating the tool have provided evidence for its reliability and validity across multiple nursing populations in Canada [13,14] and have demonstrated high levels of reliability during adaptation efforts in Australia [15]. The Digital Technology Self-Efficacy (DT-SE) scale, which measures self-efficacy in relation to digital technology, has been used in Europe, Asia, and the Arab world. These studies have demonstrated consistent reliability across regions [16,17]. Systematic review results show that when these tools are transferred to other countries, they do not always perform similarly in terms of psychometric properties. Therefore, it is essential to conduct local validation to account for variations in nursing education and practice settings.

However, no prior study has rigorously validated the C-NICAS and DT-SE scales for Saudi undergraduate nursing students, which represents a significant gap in the field. The lack of culturally adapted and psychometrically sound measures for assessing digital competency in undergraduate nursing students in Saudi Arabia does not allow educators to reliably measure baseline digital competency, assess the effectiveness of their curricula, or make evidence-based decisions for reform, as required by the digital health priorities of Saudi Vision 2030.

Therefore, this study aimed to evaluate the reliability and validity of the C-NICAS and DT-SE scales among undergraduate nursing students in Saudi Arabia to provide robust, locally validated measures of informatics competency and digital technology self-efficacy.

This study also enables a reliable measurement of students' digital readiness, which bridges the gap between knowledge and practice, supports the design of educational interventions, and provides benchmarks for educational institutions. Finally, it offers practical insights into developing a digitally competent nursing workforce and advancing cross-cultural scholarship in nursing informatics for nurse educators, curriculum developers, and policymakers. The validation of the C-NICAS and DT-SE tools in Saudi Arabia will further facilitate the ongoing evaluation of curriculum changes in digital health education through repeated assessments and targeted integration of simulation learning and hands-on experience using electronic medical records while supporting investment in digital resources and informing workforce modernization strategies for national health care transformation.

Methods

Study Design

This descriptive cross-sectional study evaluated the psychometric properties of the C-NICAS and DT-SE scale among Saudi undergraduate nursing students.

Setting, Participants, and Sampling

Students attending the College of Nursing at the University of Ha'il were recruited between February and June 2025 for the study. A priori power calculation was conducted to identify how many participants would be needed to support a one-way ANOVA, using G*Power software (version 3.1.9.7) [18] with a small-to-medium effect size (f=0.25), an α level of .05, and a statistical power of 0.80. Two hundred students were required to achieve these parameters.

The most practical and efficient method for recruiting a sample within the confines of the project timeline and budget was convenience sampling. This sampling strategy allowed for the recruitment of students across multiple academic years/levels and facilitated a broader representation of student participation. However, the use of convenience sampling also introduced a risk of selection bias, in that students who were more readily available and/or engaged may have been overrepresented. Additionally, limiting recruitment to a single institution restricted the generalizability of the findings, as they may not have accurately reflected the larger population of Saudi nursing students in the country. Therefore, future studies should use multi-institutional or probability-based sampling designs to increase the representativeness and external validity of their findings.

XSL•FO
RenderX

The inclusion criteria were as follows: active students in the nursing program who were aged 18 years or older, were fluent in English, and provided informed consent. Students in their preparatory year, non-nursing majors, students on leave, those who withdrew, and visiting students not affiliated with the college were excluded. An additional 20% of the originally calculated number of participants was included to allow for attrition and missing data in participant responses.

Rationale for Instrument Versions

Two valid instruments were used in this study. The first was C-NICAS version 2, the most recent peer-reviewed version of an instrument that represents the current informatics standards accepted throughout international competency frameworks. Research has supported the reliability and relevance of the domains of this instrument for measuring nursing informatics competency worldwide; therefore, it was determined to be appropriate for establishing benchmarks in nursing informatics competencies for undergraduate nursing education in Saudi Arabia. The second instrument was the DT-SE scale [19], which has been shown to have high psychometric properties (α>.90) and has been successfully adapted in several cultures. This scale can measure and compare self-efficacy for digital health tasks among nursing students with some degree of reliability and comparability. Both instruments provided evidence-based and internationally comparable assessments while providing locally validated measures for use within the Saudi context.

Survey Instrument

The survey tool was divided into two components: part 1 contained demographic questions regarding age, gender, level of education, prior experience with EHRs, and individual self-perception of digital readiness. Part 2 contained the C-NICAS version 2 (4 subscales with 26 items), a tool designed to measure competency in 4 areas: foundational computer skills, information and knowledge management, professional and regulatory accountability, and use of computers in patient care. The DT-SE (17 items) measures individual self-efficacy for completing digital health tasks (Likert scale: 1="strongly disagree" to 4="strongly agree"; some items were reverse scored); higher scores represent greater digital self-efficacy.

Data Collection

Data were collected from the participants using anonymous online surveys administered through a secure web-based platform. Withdrawal from the study was permissible at any time . All items were completed in a self-report format, and the participants submitted their responses electronically upon completing the survey.

Data Analysis

Following data collection, all responses were exported to SPSS Statistics for Windows (version 29; IBM Corp) for data cleaning and analysis. Descriptive statistics (mean, median, SD, and frequency distribution) were computed to summarize the sociodemographic characteristics and overall scores on the C-NICAS and DT-SE. Reliability analyses were conducted to estimate the internal consistency coefficients for each scale and subscale, and exploratory and confirmatory factor analyses were performed to evaluate the underlying factor structures and model fit of the C-NICAS and DT-SE. Mean imputation was applied to address missing values for continuous variables, whereas mode imputation was used for missing categorical variables. Python was used to generate supplementary data visualizations to support the interpretation and presentation of the findings.

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Ha'il (approval H-2024 - 437). Online informed consent was obtained from each participant before the survey was initiated. The responses were anonymous and stored in a secure location on a password-protected server that only the research team could access. Participation in the study was voluntary and did not result in any penalties. No incentives were provided for participation.

Results

The demographic information of the 243 Saudi nursing undergraduates is presented in Table 1. Of the 243 participants, 110 (45.5%) were aged 20 years or less, 116 (47.7%) were aged between 21 and 25 years, and 17 (7%) were aged 26 years or more. The majority of participants were women (159/243, 65.4%) and a minority were men (84/243, 34.6%). There were 69 (28.4%) first-year students, 72 (29.6%) second-year students, 39 (16%) third-year students, and 63 (25.9%) fourth-year students. Of the 243 participants, 124 (51%) reported that they had completed some type of informatics-related education prior to participating in this study, and 119 (49%) stated that they had not completed any type of education related to informatics.

	Excellent	158 (65.0)
Career area		
	Clinical care	130 (53.5)
	Academic/teaching	35 (14.4)
	Public health/community	17 (7.0)
	Administration/leadership	14 (5.8)
	Informatics	14 (5.8)
	Undecided	33 (13.6)

XSL•FO
RenderX

Of the 243 participants, 47 (19.3%) stated that they felt very uncomfortable using digital technology, 53 (21.8%) felt uncomfortable, 54 (22.2%) felt neutral about using digital technology, and 89 (36.6%) felt comfortable. Of the participants, 72 (29.6%) stated that they had never seen an EHR before, 98 (40.3%) reported seeing EHRs monthly or less, and 73 (30%) reported using EHRs every week or more.

A large proportion of participants (194/243, 79.8%) either owned their own computers/laptops or had regular access to them. However, 49 (20.2%) participants indicated that they did not have regular access to a personal computer/laptop. Regarding the use of technology for educational purposes, 11 (4.5%) reported that they used this technology monthly, 32 (13.2%) used it weekly, and 200 (82.3%) reported that they used it daily.

In terms of accessing the internet at home, 19 (8.7%) of the participants rated their access as fair, 66 (27.2%) rated their access as good, and 158 (65%) rated their access as excellent. When asked what areas of nursing they planned to pursue after graduation, 130 (53.5%) of the participants planned to pursue roles in direct patient care in hospitals or clinics, 35 (14.4%) wanted to pursue roles in academia or as educators, 17 (7%) wanted to pursue roles in public health/community nursing, 14 (5.8%) wanted to pursue administrative/leadership roles, 14 (5.8%) were interested in pursuing roles in nursing informatics, and 33 (13.6%) were undecided about what area of nursing they would pursue.

Table 2 presents descriptive statistics for the C-NICAS and DT-SE scales. Mean scores across the C-NICAS domains were relatively consistent, including information and communication technology (ICT) skills (mean 2.6, SD 0.93), knowledge (mean 2.5, SD 0.87), accountability (mean 2.6, SD 0.89), and use (mean 2.6, SD 0.85). The overall mean score for the C-NICAS was 54 (SD 16.9), suggesting a moderate level of informatics competency among the students. The mean DT-SE score was 2.7 (SD 0.56), indicating moderate self-efficacy in using digital technology.

Table . Descriptive statistics of informatics competency and digital self-efficacy.

Variable	Scores, mean (SD)
Foundational information and communication technology skills	2.6 (0.93)
Information and knowledge management	2.5 (0.87)
Professional and regulatory accountability	2.6 (0.89)
Use of information and communication technology in patient care	2.6 (0.85)
Overall C-NICAS[a]	54 (16.9)
DT-SE[b]	2.7 (0.56)

[a]Canadian Nursing Informatics Competency Assessment Scale.

[b]Digital Technology Self-Efficacy.

Table 3 summarizes the reliability testing results for the C-NICAS. Cronbach α values indicated good to excellent internal consistency for all domains: foundational ICT skills (α=0.70), information and knowledge management (α=0.80), professional and regulatory accountability (α=0.82), and use of ICT in patient care (α=0.90). The overall the C-NICAS demonstrated excellent reliability (α=0.90). The DT-SE scale showed good reliability (α=0.80).

Table . Internal consistency reliability of the Canadian Nursing Informatics Competency Assessment Scale (C-NICAS) and Digital Technology Self-Efficacy (DT-SE) scale.

Scale	Items, n	Cronbach α	Level of internal consistency
Foundational information and communication technology skills	2	0.70	Good
Information and knowledge management	6	0.80	Good
Professional and regulatory accountability	6	0.82	Good
Use of information and communication technology in patient care	10	0.90	Excellent
C-NICAS	26	0.90	Excellent
DT-SE	17	0.80	Very good

XSL•FO
RenderX

Factor Structure of C-NICAS

Exploratory factor analysis supported a multidimensional structure for the C-NICAS, with item commonalities in an acceptable range and excellent sampling adequacy (Kaiser-Meyer-Olkin=0.976). Confirmatory factor analysis indicated an acceptable model fit for the 4-factor model (comparative fit index=1.000; incremental fit index=1.000; root mean square error of approximation=0.081; χ^2_1=2.02). The full factor loading matrix and related statistics are presented in Table 1 in Multimedia Appendix 1, with the corresponding factor loading plot in Figure 1 in Multimedia Appendix 1 and detailed CFA fit indices in Table 2 in Multimedia Appendix 1.

Factor Structure of DT-SE

For the DT-SE, sampling adequacy was strong (Kaiser-Meyer-Olkin=0.930), and 3 factors emerged in the exploratory factor analysis, explaining 67.7% of the total variance. The rotated factor loadings and variance explained are shown in Tables 3 and 4 in Multimedia Appendix 1, and the factor-loading plot is shown in Figure 2 in Multimedia Appendix 1. Confirmatory factor analysis of the DT-SE indicated a suboptimal model fit (χ^2_{119}=877.10; comparative fit index=0.76; root mean square error of approximation=0.146), suggesting the need for further refinement of the scale in this context. The detailed CFA indices are summarized in Tables 5 and 6 and Figure 3 in Multimedia Appendix 1.

Discussion

In this cross-sectional study, the C-NICAS demonstrated excellent internal consistency and a stable multidimensional factor structure, confirming its suitability for assessing informatics competency among undergraduate nursing students at this Saudi institution. The DT-SE scale showed good internal consistency and an interpretable factor structure, although some model fit indices indicated that further refinement may enhance its performance. Overall, the participants reported moderate levels of informatics competency and digital technology self-efficacy, with stronger foundational ICT skills than advanced digital readiness.

Psychometric Properties of C-NICAS and DT-SE

This reliability/validity assessment found that the C-NICAS [20] and DT-SE scale were both highly reliable and valid and thus appropriate for assessing informatics competency and self-efficacy in an educational setting of this type. The strong psychometric properties of both scales indicate that items within each scale group appropriately represent the theoretically supported domains and thus provide a meaningful assessment of competency and self-efficacy among undergraduate nursing students at the University of Ha'il in Saudi Arabia.

The results support similar validation assessments in Canada [21] and demonstrate that the C-NICAS has excellent internal consistency and a valid factor structure across multiple cohorts of undergraduate nursing students. Another similar validation assessment [22] for the Arabic version of the Self-Assessment Nursing Informatics Competencies Scale, which showed high reliability when used to assess nursing informatics competency among Arab nursing students, further supports the use of these measures to assess informatics competency in the Saudi educational context. Together, these studies demonstrate that valid and reliable scales are important for measuring nursing informatics competency.

Conte et al [23] pointed out that there is a possibility of reduced reliability when adapting self-efficacy scales to different cultures. Furthermore, a systematic review of the literature by Al-Qudah et al [24] concluded that nursing informatics scales exhibit variable reliability and validity, depending on the specific population and setting. Both research groups agreed that these scales must be refined and validated over time if they are to be used effectively on an international scale.

Validated and reliable measures of nursing informatics competencies and self-efficacy will provide Saudi nursing educators with data to assess students' readiness to learn, identify strong and weak areas, and provide an evidence base for changes in nursing education programs. The use of valid tools also supports continuing education and contributes to the transformation of the Saudi Arabian health care system by linking nurses' skills to the national digital health objectives.

Although the scales have strengths, their two main limitations are generalizability and fit for culture (especially for the DT-SE). Studies using larger samples and multiple iterations of the scales would assist in further refining the tools, following the authors' recommendations, to ensure continued utility and reliability as standards for health care and informatics continue to evolve in the Kingdom of Saudi Arabia.

Informatics Competency and Digital Self-Efficacy Levels

This study indicates that the undergraduate nursing students at this institution have an average level of informatics competence and a moderate amount of digital self-confidence; thus, they have partially adopted the digital requirements of today's health care environment but demonstrate a gap between what they are taught about clinical informatics and how they apply it in the workplace. Students have digital skills and confidence in performing these tasks; however, their ability to apply and integrate these skills into more complex applications is less developed than their basic skills.

Compared with their global counterparts, nurses in Jordan demonstrated an almost identical profile of moderate-to-high levels of informatics competency as the participants in this study, including strong performance in general basic computer skills and much weaker performance in clinical informatics subdomain areas [25]. A similar pattern has been observed in Australia and several other Arab countries, as well as in many other parts of the world, where nursing students have shown evidence of being competent in routine digital use; however, they are often found to be lacking in specialized areas such as system management and decision-making [26-29]. The similarities among these findings support the notion that this issue is universal in nature.

Recent studies have also reported similar patterns in nursing informatics education. One recent study found that nursing students typically show higher competence in basic computer

XSL•FO
RenderX

skills than in clinical information management and decision support tasks [6]. A further study proposed an undergraduate informatics blueprint that stressed progressive development from foundational to advanced competencies and explicit alignment with IMIA and TIGER recommendations, supporting the need for structured, longitudinal integration of informatics in nursing programs [29].

The level of self-confidence exhibited by nurses regarding digital abilities was similarly modest and reflects current global trends, where confidence in using technology for everyday tasks is commonplace, yet proficiency is limited in advanced applications of informatics [13,30]. While early exposure to digital tools, along with some education, support, and resources, has contributed to moderate progress in improving digital self-efficacy among Jordanian nursing students, limitations remain owing to the lack of preparation in advanced informatics, varied faculty expertise, and inconsistency in the availability of adequate technology and digital systems to support digital readiness [3]. Generational changes and increased digital exposure are likely to improve the basic competencies of nursing students; however, instructional and systemic barriers persist.

The data indicate that nursing programs in Saudi Arabia, including the program at this institution, have made some advancements in digital health; however, further strategic investments are needed to fully support the curriculum design, faculty development, and experiential learning necessary to meet the needs of clinical practice. The use of validated assessments, simulations using artificial intelligence technology, and increased emphasis on interprofessional informatics education will be the key next steps [4,31]. Ultimately, while moderate competency and self-efficacy levels suggest an advancement toward meeting the goals of Saudi Vision 2030, the overall implication of this study is that there continues to be a need for strategic reforms at all educational levels to ensure that graduates can assume leadership roles in future digitally advanced health care systems.

Implications for Nursing Education and Curriculum Development

This research has provided many critical findings that are relevant to nursing education, nursing program assessment, and curriculum development here and potentially elsewhere in Saudi Arabia, in support of Saudi Vision 2030 and global digital transformation objectives in health care.

First, because the nursing students in this sample possessed average levels of informatics competence and digital self-efficacy, there is an imperative for nursing curricula to enhance students' learning experiences with respect to digital health and informatics. For example, rather than simply exposing students to digital health as part of their introductory courses, nursing programs should systematically integrate advanced informatics education, simulation-based learning, EHR training, and education on artificial intelligence and decision support systems into the 4-year undergraduate nursing education experience. By doing so, students will be able to progress from a beginner level of digital literacy to being capable of effectively using emerging technologies in the delivery of patient care.

Second, by using these assessments (the DT-SE and C-NICAS) systematically, educators will be empowered to use data-driven insights when making decisions about the ongoing evaluation of nursing programs and curriculum enhancements. Ongoing assessment of nursing students' informatics competence will empower educators to assess potential weaknesses in their students' abilities to engage in clinical practice using digital technologies, adapt to new clinical requirements, and modify the content of their curricula to be consistent with national and international priorities related to digital health.

Additionally, these enhancements will directly contribute to the goals of Saudi Vision 2030, specifically by providing a future-ready nursing workforce that can assist in promoting and implementing advancements in health care through engagement in national eHealth initiatives and the provision of technology-enabled patient care. Furthermore, to ensure the sustainability of the positive outcomes of this study and to continue to use best practices in both educational and clinical environments, it is important for faculty to continuously receive professional development and for the institution to invest in its digital infrastructure.

Finally, the results of this study further emphasize the importance of innovation in curriculum design and competency-based education in developing nurses with the ability to meet the challenges associated with the digital transformation of health systems globally. Through the alignment of nursing education in Saudi Arabia (particularly in institutions similar to the one in which this study was conducted) with these principles, the health care system will be able to develop professionals who can deliver high-quality, safe, technology-enhanced care to patients.

Study Limitations

This study had several important limitations. The generalizability of the findings is limited by the use of a convenience sample recruited from only one university, and the results should therefore be interpreted as reflecting the students at this institution rather than all Saudi nursing students. Since participants were asked to report their own behavior, there is a potential for both recall and social desirability biases due to the self-reporting nature of the items. Furthermore, the cross-sectional nature of the research design precludes making causal statements about the relationships observed between variables, and possible scale adaptation issues may limit the accuracy of the scales in representing the context being studied. There is a possibility that non-response (dropout) bias may have affected the findings as well, because less technologically savvy students may not have been represented.

Recommendations

To address the gaps identified in this study, we recommend that curriculum developers continue to develop and implement advanced informatics content, simulation-based learning, and practical EHR training across undergraduate nursing programs at this and other institutions in Saudi Arabia. In addition, opportunities for faculty development and long-term investments in digital infrastructure are required to support and enhance the digital health competencies of nursing faculty members.

XSL•FO
RenderX

Policymakers should also provide incentives for the continued implementation and development of standardized and psychometrically sound assessment tools, such as the C-NICAS and DT-SE, for the ongoing monitoring and evaluation of curricula at both the institutional and national levels. We believe that this will help Saudi nursing graduates in an increasingly digitalized health care environment.

Future studies should use multi-institutional, longitudinal research designs and incorporate culturally appropriate tools to increase the representativeness of findings and enable follow-up assessments of curricular impact over time. Future research should also include refinement of the DT-SE scale to improve model fit and identify targeted interventions (eg, simulation and AI-based informatics training) to address existing gaps in advanced digital preparedness among nursing students. Future research examining the association between nursing students' informatics competency and patient outcomes will help optimize nursing education to meet national and international priorities.

Conclusion

The validation of assessments that measure digital competency and self-efficacy is necessary to enhance nursing education in Saudi Arabia. This descriptive cross-sectional study administered the C-NICAS and DT-SE to undergraduate nursing students at a Saudi university, finding that both scales demonstrated strong psychometric properties. The results indicated that nursing students displayed moderate levels of informatics competency and digital technology self-efficacy; specifically, they demonstrated adequate basic-level skills but lacked advanced digital competence compared to international standards. The results indicate the urgent need for comprehensive curriculum reform, faculty development, and strategic investments in advanced technology and assessment techniques to ensure that future nursing graduates are prepared to meet the demands of digital health care delivery systems. The data support the alignment of education with the provisions of Saudi Vision 2030.

Abstract

Background: Nursing informatics is essential for digital health transformation; however, the technology acceptance of undergraduate nursing students in Saudi Arabia remains underexplored.

Objective: This study examined factors influencing nursing students' intention to use informatics technologies using the technology acceptance model.

Methods: A cross-sectional survey was conducted with 132 undergraduate nursing students. Data were analyzed using descriptive, correlational, and hierarchical regression analyses.

Results: Perceived usefulness (mean 3.68, SD 1.22) and perceived ease of use (mean 3.64, SD 1.32) were the strongest predictors of acceptance, together explaining 87% of the variance (R^2=0.87; β=0.323 for usefulness, P<.001; β=0.195 for ease of use, P=.032). Only 25.8% (n=34) of the students often used electronic health records, while 31.8% (n=42) had no electronic health record experience, indicating a clear gap in practical informatics exposure.

Conclusions: Nursing students' acceptance of informatics is primarily driven by its perceived usefulness and perceived ease of use. These findings highlight the urgent need to integrate practical, user-centered informatics training and clinical simulation into undergraduate nursing curricula to better prepare students for technology-based practice.

KEYWORDS

nursing informatics; technology acceptance model; TAM; digital health; nursing students; informatics

Introduction

The integration of nursing informatics has emerged as a key issue in improving health care delivery, particularly in rapidly changing contexts [1,2], such as Saudi Arabia. Nursing informatics, which serves to bridge information science, computer science, and nursing, can make substantial advances in nursing practice and management through advanced technology usage [3-5]. The effective adoption of systems such as electronic health records (EHRs), clinical decision support tools, and computerized physician order entry is vital for reducing medical errors [6], enhancing patient safety [7], improving care coordination [8], and directly supporting national quality goals. Considering the ambitious objectives of Saudi Arabia's Vision 2030 to digitize and transform its health care industry [9], the practicality of technologies used by the next generation of practitioners is important and perhaps even imperative. Despite the emerging national need, the acceptance and ability of undergraduate nursing students to engage in nursing informatics for implementation are quite concerning and warrant further research [8,10-12].

Recent studies have highlighted issues related to informatics education in Saudi Arabia. In general, nursing students are aware of the importance of nursing informatics; however, their practical acceptance and use are limited in scope for several related reasons, such as a lack of curricular content, limited clinical experience with informatics, and a lack of consistent faculty support [10,13]. In these attempts, there is a definite disconnect between the theory taught and the actual informatics competencies students need in the clinical environment. This highlights the need for the reform of education due to its limited examples of hands-on training and the development of curricular content that aligns more closely with the current informatics standards in health care delivery [14-17]. Thus, the primary research problem addressed by this study was the lack of empirical understanding of the factors that specifically predict

XSL•FO
RenderX

the adoption and use of nursing informatics among undergraduate nursing students in Saudi Arabia, which is a necessary step before effective educational interventions can be designed.

To provide an empirical investigation of this gap, this study uses the established technology acceptance model (TAM) and aims to precisely investigate how undergraduate nursing students' personal perceptions—namely, perceived usefulness (PU) and perceived ease of use (PEOU) of informatics systems—predict their behavioral intention to use those technologies. This study provides a link between identified gaps in the curriculum, experiences, and measurable psychological factors.

A compelling theoretical framework is required to determine the gaps in this study. TAM, developed by Davis [18], is one of the most important and widely used models for studying users' willingness to adopt new technologies. This framework helps us study their main perceptions, PU, and PEOU of nursing informatics systems. The current literature helps to report these general barriers, but a quantitative study using the published and validated TAM framework that focuses on and measures acceptance of these general perceptions of nursing informatics by Saudi Arabian nursing students is nonexistent.

This study extends the core TAM by incorporating contextual factors relevant to nursing informatics education. Social influence was conceptualized in line with TAM2 [19], reflecting perceived expectations from peers, faculty, and clinical environments. Engagement and Sustainability were included as contextual constructs, capturing students' interactions with informatics technologies and their perceptions of their long-term relevance in clinical practice. These variables were examined as supplementary variables rather than primary predictors of acceptance. Although more recent models, such as TAM3 and the unified theory of acceptance and use of technology, incorporate additional contextual and organizational factors, the original TAM was selected for its parsimony and proven applicability in educational and early-stage technology adoption contexts.

As such, this study used the TAM framework in a quantitative study on nursing students' acceptance of nursing informatics in Saudi Arabia. Using the TAM framework, this study is a cross-sectional survey focused on how PU and PEOU affect students' behavioral intention to adopt informatics and provides empirical research and direction for educational policy and curriculum development in alignment with Vision 2030. Despite the recognized importance of nursing informatics in supporting digital health transformation, undergraduate nursing students in Saudi Arabia continue to have limited practical exposure to and variable acceptance of informatics technologies. The factors influencing the intention to adopt and use these technologies remain insufficiently understood, particularly within a theory-driven framework.

Therefore, this study aimed to identify factors that predict undergraduate nursing students' acceptance of nursing informatics technologies using the TAM. The following research questions guided this study: What are undergraduate nursing students' perceptions of nursing informatics in terms of PU, ease of use, and acceptance? What relationships exist between the core TAM constructs and nursing students' acceptance of informatics technologies? Which TAM-related factors significantly predict undergraduate nursing students' acceptance of nursing informatics technologies?

Methods

Research Design

This study used a quantitative, cross-sectional survey to investigate the factors affecting the intention to use informatics technologies, using the TAM as a framework. A cross-sectional survey design was selected for its practicality and feasibility in capturing undergraduate nursing students' perceptions and acceptance of informatics technologies at a single point in time. This design is appropriate for examining the relationships among TAM constructs and identifying key predictors of acceptance without the resource demands associated with longitudinal data collection. This study is reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement guidelines (Checklist 1) [20].

Population and Sampling

This study involved third- and fourth-year undergraduate nursing students from the University of Hail in the Hail Region, Saudi Arabia, from October 2025 to December 2025. Participants were recruited using convenience sampling from students who had successfully completed a nursing informatics course and had relevant clinical experience. All qualified students were contacted via a university communication system. This sampling strategy may limit the generalizability of the results; however, it also facilitates the recruitment of students with proper knowledge and clinical experience. Eligible participants were third- and fourth-year undergraduate nursing students who had successfully completed the nursing informatics and core clinical nursing courses, including supervised clinical training as part of the undergraduate curriculum. Completion of these courses ensured that participants had foundational theoretical knowledge of nursing informatics and prior exposure to clinical practice environments in which health information technologies were used.

A priori power analysis was conducted using G*Power software (Mac and Windows, University of Düsseldorf) for hierarchical multiple regression. The analysis assumed an α level of .05, statistical power of 0.80, and a medium effect size (f^2=0.15). The analysis indicated a minimum sample size of 118 participants. A total of 150 students were invited, of whom 132 completed the survey, yielding a response rate of 88%.

Instrument

This study is comprised of 2 main parts. The first part explored the demographic and technology profiles of undergraduate nursing students participating in the study. The variables of interest included age, sex, year of study, comfort level with digital technology, previous experience using EHRs, computing access, frequency of technology use for educational purposes, Internet access at home, and planned area of nursing work.

XSL•FO
RenderX

The second part used the TAM questionnaire, modified from Davis [18], to measure students' perceptions and behavioral intentions regarding their use of health informatics technologies. The instrument measured 3 core constructs: PU, PEOU, and behavioral intention (BI). Items that further explored issues such as subjective norms (SNs; social influence), sustainability, engagement, and willingness to learn new technologies were also assessed. The TAM items were adapted from a study by Davis [18] and expanded to include domains relevant to contemporary digital health education, namely sustainability, engagement, and willingness to learn new technologies. The final instrument consisted of 31 items distributed across 7 constructs: PU (6 items), PEOU (6 items), SNs (2 items), sustainability (4 items), engagement (7 items), and learning new technologies (6 items). Participants rated their responses on a 5-point Likert scale (from 1="Strongly Disagree" to 5="Strongly Agree"), and the total scores ranged from 12 to 60. Higher ratings indicated that nursing students had more positive opinions about the usability of artificial intelligence in health care. The questionnaire was administered in English, which is the official language of instruction in the nursing program, and all participants were proficient in English. Therefore, no translation or back-translation procedure was required.

Minor wording adjustments were made solely to contextualize the items to nursing informatics and EHR use (eg, replacing generic references to "technology" with "nursing informatics systems"), without changing the meaning or theoretical intent of any item. The underlying structure and theoretical integrity of the original TAM instrument were maintained.

Prior to the main data collection, the instrument was pilot-tested with 20 second-year undergraduate nursing students to assess its clarity, reliability, and internal consistency. These students were excluded from the final sample. Feedback from the pilot test resulted in minor wording refinements to improve item clarity, while the overall structure of the instrument remained unchanged. Internal consistency demonstrated good-to-excellent reliability across constructs in the pilot test, with Cronbach α values of PU=0.953, PE=0.900, SN=0.929, sustainability=0.917, engagement=0.932, and learning new technologies=0.911, indicating satisfactory psychometric properties of the instrument.

Ethical Considerations

After obtaining institutional review board approval from the University of Hail (H-2024 - 437 on September 16, 2024), an ethical recruitment method was established. The purpose of the study was shared with the nursing students in the classroom, and the students were invited to participate. A link to the survey tool was distributed to the students via WhatsApp numbers and university email addresses. Data were collected electronically using Google Forms. Informed consent was obtained electronically through Google Forms. The anonymity and confidentiality of the participants were maintained throughout the study. Moreover, participants were informed that there were no incentives or compensations for participating in this study. Google Forms was chosen for its ease of access and reliable data storage capabilities, providing an efficient process for collecting information on undergraduate nursing students' informatics competencies.

The survey began with an introductory page outlining the purpose of the study, assurances of anonymity, and details of voluntary participation. Participation was voluntary, and the students were informed that they could withdraw at any time without penalty or impact on their academic standing. Data were collected anonymously using Google Forms, and no identifying information was obtained. Access to the data was restricted to authorized members of the research team to ensure confidentiality and data security. The study involved minimal risk and adhered to ethical principles throughout the recruitment and data-collection processes.

Two reminders (1 email and 1 in-class announcement) were used to increase the response rates.

Statistical Analysis

The data were analyzed using IBM SPSS Statistics (version 27). Descriptive statistics were used to summarize participants' demographic characteristics and study variables. Pearson correlation coefficients were calculated to examine the relationships among the TAM constructs. Hierarchical multiple regression analysis was conducted to identify the predictors of nursing students' acceptance of informatics technologies. In model 1, demographic and technology-related control variables (age, gender, year level, prior informatics training, exposure to EHRs, comfort with technology, frequency of technology use, internet accessibility, and intended future nursing career) were entered. In model 2, the core TAM variables—PU and PEOU—were added. Model 3 included extended TAM-related variables (SN, sustainability, engagement, and willingness to learn new technologies).

Before the analysis, the assumptions of multiple regression were examined. The normality of residuals and linearity were assessed through visual inspection of the residual plots. Multicollinearity was evaluated using variance inflation factor values, all of which were within acceptable limits. Statistical significance was set at $P<.05$ for all analyses.

Results

Most participants were female (n=113, 85.6%) and aged 21 to 25 years (n=96, 72.7%). Although access to technology was high, 76.5% (n=101) reported access to a personal computer, and 79.5% (n=105) used technology daily for educational purposes. Comfort with digital technology varied, and clinical informatics exposure remained limited. Only 25.8% (n=34) of the students reported frequent use of EHRs, while 31.8% (n=42) had no prior EHR experience. Clinical care was the most common career pathway (n=80, 60.6%; Table 1).

Academic or teaching role	11 (8.3)
Nursing informatics	8 (6.1)
Public health or community nursing	7 (5.3)
Clinical care (hospital or clinical setting)	80 (60.6)

[a]EHR: electronic health record.

The descriptive statistics for the study variables are presented in Table 2. Among the TAM constructs, PU (mean 3.68, SD 1.22) and PEOU (mean 3.64, SD 1.32) had the highest mean scores, indicating generally positive perceptions of nursing informatics. Learning new technologies (mean 3.61, SD 1.13) and overall acceptance (mean 3.60, SD 1.24) were also rated positively. In contrast, SN had the lowest mean score (3.21, SD

XSL•FO
RenderX

1.22), suggesting that social influence played a less prominent role in students' perceptions than individual cognitive factors.

Table . Descriptive statistics of study variables.

Variable	Value, mean (SD)
Acceptance	3.60 (1.24)
Perceived usefulness	3.68 (1.22)
Perceived ease of use	3.64 (1.32)
SN[a]	3.21 (1.22)
Sustainability	3.50 (1.20)
Engagement	3.35 (1.15)
Learning new technologies	3.61 (1.13)

[a]SN: subjective norm.

As illustrated in Table 3, the acceptance of nursing informatics demonstrated strong positive correlations with PU (r=0.83; P<.01), PEOU (r=0.81; P<.01), and learning new technologies (r=0.83; P<.01). Additionally, PU and PEOU were highly interrelated (r=0.82; P<.01), supporting the theoretical assumptions of TAM. SNs showed weaker, though still significant, correlations with acceptance (r=0.45; P<.01), reinforcing the comparatively limited role of social influence in this sample. Despite these strong correlations, multicollinearity diagnostics remained within acceptable limits (variance inflation factor<6), suggesting that the predictors could be reliably included in the regression models.

Table . Intercorrelations between study variables.

[e]Not applicable.

[f]P<.01 (2-tailed).

The hierarchical regression for predicting the acceptance of nursing informatics (Table 4) revealed that, in model 1, only comfort with technology was a significant predictor with a negative effect (β=−0.363; P=.05). Model 2 included PU and PEOU, and both variables were significant positive predictors (β=0.379; P<.001). The final model indicated that PU (β=0.323; P<.001), PEOU (β=0.195; P=.03), and learning new technologies (β=0.260; P=.008) were significant positive predictors.

[g]SN: subjective norm.

Table 5 summarizes the proportion of variance in the acceptance of nursing informatics explained by predictors across each step of the hierarchical regression model. In model 1, the demographic and technology-related control variables explained 45% of the variance (R^2=0.45), with an adjusted R^2 of 0.20. In model 2, when PU and PEOU were entered, the model explained 87% of the variance (R^2=0.87), with an adjusted R^2 of 0.75. In model 3, when SN, sustainability, engagement, and learning new technologies were added, the final model explained 90% of the variance (R^2=0.90), with an adjusted R^2 of 0.80. The increase in R^2 from model 1 (0.45) to model 2 (0.87) is striking; therefore, PU and PEOU are the primary predictors, and the final model has a very good overall fit.

Table . Hierarchical multiple regression.

Model	R^2	Adjusted R^2
1	0.45	0.20
2	0.87	0.75
3	0.90	0.80

Table 6 displays hierarchical regression, revealing that all models predicting acceptance of nursing informatics were statistically significant. In model 1, which included demographic and technological controls, the regression was significant ($F_{9,122}$=3.503; P<.001), accounting for a small amount of variance in acceptance. Model 2, which included the core TAM constructs (PU and PEOU), showed a substantial increase in the variance explained ($F_{11,120}$=32.442; P<.001), confirming the primary role of these 2 constructs in acceptance behavior. Model 3 also showed a strong statistically significant outcome ($F_{15,116}$=32.024; P<.001), as it included all 7 study variables and accounted for the largest amount of variance explained. The increasing values of the F test and the consistent statistical significance across the models indicate that the contextual variables and TAM constructs work in succession to predict students' acceptance of nursing informatics.

Table . ANOVA summary for hierarchical regression predicting acceptance[a].

Model	Sum of squares (regression)	Sum of squares (residual)	Mean square (regression)	Mean square (residual)	F test (df)	P value
1	41.527	160.702	4.614	1.317	3.503 (9, 122)	<.001[b]
2	151.339	50.890	13.758	0.424	32.442 (11, 120)	<.001[b]
3	162.893	39.336	10.860	0.339	32.024 (15, 116)	<.001[b]

Discussion

Perceptions and Acceptance of Nursing Informatics

Nursing students have a strong, positive perception of nursing informatics, recognizing these technological tools as practical resources that contribute to the quality and safety of patient care, which supports national modernization strategies for digital health in the sector. Consistent with the present findings, Al-Olaimat et al [21] reported that perceived usefulness is a strong predictor of nursing students' acceptance of health information technologies, underscoring the importance of clinical relevance. Similarly, Alnajjar et al [22] found that perceived ease of use significantly influenced technology adoption among nursing students, aligning with our results that usability remained central to informatics acceptance.

However, positive perspectives on nursing informatics and the use of technology are not universal and have exposed serious challenges to implementation. Studies have shown negative or mixed perspectives on nursing informatics and technology use, especially among students who have received little or no training. Given this gap between positive and negative experiences, nursing curricula should incorporate core informatics competencies across all training levels.

Correlation Between TAM Domains

The high positive correlations found between factors influencing nursing students' acceptance of informatics technologies and their perceptions of usefulness, ease of use, and learning opportunities indicate that these personal factors are the primary drivers of adoption. This is not surprising, as students are inherently drawn to technologies that optimize their work, are easy to navigate, and directly advance the acquisition of important professional skills; these direct personal advantages ultimately fulfill their pragmatic and professional needs.

Conversely, the study results indicate that external social norms or pressures have significantly less influence. In other words, students rely on their own attitudes and experiences rather than peer or institutional pressure when making adoption decisions.

This finding is consistent with other studies showing that personal direct advantages are significant predictors of technology acceptance by nursing students and clinicians. In a 2025 cross-sectional study by Jallad et al [23], which used TAM as a research framework, students' personal factors (usefulness, ease of use, human, and technology) were highly positively correlated with informatics adoption. Moreover, their findings suggest that personal advantages still matter even in the presence of institutional support. Similarly, Aldosari et al [24] found a highly positive correlation between PU and PEOU, which led to positive acceptance of health information technologies by nurses. Nguyen et al [25] likewise found that, especially for clinicians, PU and PEOU had an exceptionally influential effect on information and communication technologies acceptance, typically outweighing social influence.

Although these data likely emphasize personal factors, other studies indicate the opposite premise, where external social influence is stronger, at least comparable to, or even better than personal benefits, indicating that context affects the degree of influence. For example, Warshawski [26] found that social influence, performance expectancy, and facilitating conditions

XSL•FO
RenderX

were important variables that positively contributed to nursing students' use of technology in Israel. Furthermore, Garavand et al's [27] systematic review made similar assertions regarding the importance of social impacts (eg, peer and institutional support), noting that they were not always weighted as heavily as personal factors.

Factors Influencing the Acceptance of Nursing Informatics

This study explored the factors influencing the prospective acceptance of nursing informatics by Saudi undergraduate nursing students. Overall, the findings highlight individuals' central and predominant personal perceptions as predictors of technology acceptance in this population, which is congruent with the underlying theoretical principles of the TAM. The input of cognitive and social variables provides institutions with practical recommendations to support the integration of informatics into the nursing education curriculum, which is pertinent, as the Saudi health care system continues to progress through digital changes.

The final structural model provided solid empirical support for the fundamental TAM constructs, highlighting that PU, PEOU, and students' ability and willingness to learn new skills are statistically significant positive predictors of perceived technology acceptance. The findings demonstrated that PU and PEOU were related to a positive and significant degree of perceived acceptance and were consistent with the fundamental TAM assumptions and an extensive array of empirical literature in health care. PU and PEOU were strongly and positively correlated with perceived acceptance. This is consistent with the fundamental premise of TAM, which posits that students who perceive informatics systems to be useful in their education and future desired clinical experience (PU) and easy to understand (PEOU) will act to adopt the technology. The existing literature, including studies on Saudi nursing students and practicing nurses [24,28-30], suggests that of all the elements explored, only 2 personal cognitive constructs, PEOU and PU, are consistently shown to have the greatest significance. The literature also describes how PEOU and PU are often interrelated, thereby bolstering their interconnected predictive ability [31], which may have contributed to the predictive ability of the present model.

In contrast, the endogenous variables of SN, sustainability, and engagement were not statistically significant, suggesting that these were even less important than personal experience with PEOU and PU. This suggests that social influence (SN), long-term environmental sustainability, and active engagement with technology (sustainability and engagement) did not influence the initiation of acceptance in this student population. While SN being nonsignificant is consistent with some uses of TAM, where personal interest overcomes the social element, sustainability and engagement are not significant and inconsistent with an emerging corpus of published research in the e-learning and health informatics space that has identified that user engagement, perceived enjoyment, and organizational support (variables conceptually associated with sustainability and engagement) could become predictive, particularly if the use was measured in a temporally posterior fashion [32,33].

The initial observation that PU and PEOU are key drivers of technology acceptance, whereas SN, sustainability, and engagement are not statistically significant, has important context. This finding indicates that, for initial adoption, personal internal motivation (use and ease) is more important than social pressure. Similarly, SN, sustainability, and engagement not being significant were probably affected by students' exposure to informatics systems (eg, EHRs) not being large-scale, and dimensions regarding long-term and organizational support do not have enough influence on study acceptance at the beginning of use.

This is consistent with TAM in the health care sector. Reviews have always supported PU and PEOU as dominant predictors and found that SN and its related constructs were nonsignificant [31]. Health care studies have shown that internal cognitive processes outweigh social influences on clinicians and students in novice settings [24,25,29]. The lack of predictive ability for sustainability and engagement constructs also aligns with the results in the context of a lack of practical experience [34,35].

However, this inverse result was also demonstrated. Research in learning technology or mobile health usually reports engagement or sustainability properties (such as enjoyment or organizational support) as significant [32,33] when examined in a technology-rich or long-term context.

Thus, the differential results highlight an important caveat. Although PU and PEOU drive acceptance for this undergraduate sample, the lack of importance of the other constructs may be a contextual (temporal and situational) feature of the participants' inexperience when using the systems in their educational (and possibly first) experiences with such systems. Consequently, participants may regard SN, engagement, and sustainability as collectively gaining importance as predictors later (ie, when adults have graduated and worked for a while in actual practice with longitudinal interactions with complex systems). Organizational support and peer influence have a greater impact in an institutional environment and lay the groundwork for future longitudinal studies.

The nonsignificant effects of social influence, engagement, and sustainability may reflect students' limited and largely theoretical exposure to informatics technologies. At this early stage, acceptance appears to be driven primarily by PU and PEOU, whereas contextual and organizational factors may become more influential during prolonged or mandatory system use in clinical practice. Overall, our findings support the classic TAM perspective that usability and use dominate early acceptance decisions, whereas social factors may play a greater role in long-term use or in highly structured environments.

Incremental Value of TAM Predictors

The hierarchical regression analysis demonstrated the incremental value of TAM predictors in explaining nursing students' acceptance of informatics technologies. While demographic and background variables accounted for a moderate proportion of the variance, their explanatory power was substantially enhanced by the inclusion of PU and PEOU, which emerged as the dominant predictors. This finding underscores that acceptance among undergraduate nursing students is driven

XSL•FO
RenderX

primarily by individual cognitive evaluations rather than contextual or social factors.

The role of demographic characteristics, ecosystem characteristics, and other common predictors of adoption, such as social influence, is negligible in comparison, further lending credence to the notion that a strategy focused on usability and functionality will best advance informatics acceptance. This pattern is expected, as a substantial amount of evidence has emerged that supports the TAM as the reigning model in health care, consistently identifying usability and PEOU as the primary predictors for nurses' and other health professionals' adoption of health records and myriad other systems [24,36,37].

While the first 2 key TAM predictors are statistically reliable, the literature is not homogeneous. However, caution should be exercised when interpreting the extent to which the other variables of technology acceptance are equally or more robust. Some studies, especially those that have combined the unified theory of acceptance and use of technology model or the information system success model as a foundation, offer examples where social influence, engagement, organizational factors, and education are the strongest predictors of technology use, such as in mobile learning [38]. Moreover, reviews have reported that facilitating conditions, technostress, system quality, and satisfaction could be as impactful as, or more impactful than the primary TAM variables, especially in social, mandated, or organizational pressure contexts [35,38,39]. This suggests that PEOU may not always be a direct predictor, as its impact may be mediated by organizational culture, trust, or policy. Additionally, the direct impacts of TAM variables can be diminished or eliminated during periods of strong compliance or external pressure [35,39]. Future research should explore additional factors that may shape nursing informatics acceptance, including technostress, system quality, and organizational support, particularly in clinical settings where informatics systems are mandatory. Longitudinal and multi-institutional studies may help clarify how these variables interact with core TAM constructs over time and across different stages of professional development.

Limitations of the Study

This study had several limitations. First, the cross-sectional design limits causal inference; longitudinal studies are needed to examine changes in informatics acceptance over time. Second, the data were collected from a single nursing program within one university in Saudi Arabia, which may limit the generalizability of the findings to other institutions or countries. Third, the use of self-reported data may introduce response and social desirability biases, and potential nonresponse bias cannot be ruled out. Finally, participants' limited prior exposure to EHRs may have influenced their perceptions of informatics acceptance.

Implication

The results indicate that PU and PEOU are key predictors of the initial acceptance of nursing informatics, reflecting students' early cognitive evaluations rather than experiential judgment. Given the limited practical exposure to informatics systems among the participants, factors related to sustained use, such as social influence, engagement, and sustainability, were not significant. These findings suggest that while usability and perceived value drive early acceptance, continued use is more likely to depend on prolonged clinical exposure, institutional support, and repeated system interaction, underscoring the need for longitudinal practice-based informatics training in nursing education. Informatics competencies should be explicitly embedded into course learning outcomes to align education with digital health practice requirements. In addition, faculty development programs are needed to prepare educators as informatics "super users" who can effectively support students in technology-rich learning environments. Beyond education, the results are relevant to policymakers and hospital administrators who play a critical role in supporting digital transformation. Investment in standardized training platforms, collaboration between academic institutions and health care organizations, and the provision of supportive clinical informatics infrastructure can facilitate smoother transitions of nursing graduates into digitally enabled health care systems.

Conclusion

This study demonstrates that undergraduate nursing students' acceptance of nursing informatics is primarily driven by perceptions of its usefulness and ease of use, despite generally positive attitudes and high access to technology. These findings highlight a persistent gap between theoretical exposure and practical informatics experience, particularly in relation to EHR use. By prioritizing user-friendly, clinically relevant informatics education and simulation, nursing programs can prepare graduates to participate effectively in Saudi Arabia's ongoing digital health transformation.

Acknowledgments

The authors express their gratitude to all the nursing students who participated in the research. No artificial intelligence tools were used.

Abstract

Background: There is limited evidence on how brief, optional virtual reality (VR) experiences can be used with first-semester nursing students as experiential learning strategies to support understanding of foundational nursing concepts, outside of mandatory coursework or full-scale simulations. Additionally, little is known about students' and teachers' perceptions of VR as a low-stakes, supplemental learning strategy introduced early in nursing education. Examining these experiences can provide insight into the pedagogical value and scalability of VR-enhanced learning within the formal nursing curriculum.

Objective: This study explored students' and teachers' experiences of a brief, optional, VR-enhanced workshop offered outside mandatory coursework in first-semester nursing education and described students' perceptions of cognitive, social, and teaching presence.

Methods: This was a cross-sectional evaluation at a Swedish public university. A single-session workshop, co-designed by nursing teachers and the university library makerspace (implementation context), combined brief headset exposures (sympathetic arousal via a short roller coaster experience and parasympathetic engagement via a short guided meditation), peer vital-sign practice (instructional aid), small-group synthesis, and a guided debrief aligned with the community of inquiry (CoI) framework. Immediately after the session, students completed a demographics questionnaire, a 7-item workshop-specific VR-perception set, and the 34-item CoI instrument, plus 2 open-ended items; teachers provided short reflections. Analyses were descriptive for quantitative data and summative content analysis of open-ended responses. Participants included 11.9% (16/134) of the invited first-semester students (mean age 25 years, SD 5.1; 15/16, 93.8% women; 6/16, 37.5% with prior VR exposure) and 3 teachers.

Results: Most students agreed or strongly agreed that VR enhanced analysis and observation (12/16, 75%), exploration of phenomena (14/16, 87.5%), conceptual understanding and engagement (13/16, 81.3%), teacher support (13/16, 81.3%), and relevance to the session (14/16, 87.5%). CoI ratings indicated moderately positive perceptions (total mean 3.36, SD 0.44 on a 5-point scale), with cognitive presence rated the highest (mean 3.48, SD 0.41) and exploration being the top subdomain (mean 4.48, SD 0.49); design and organization and facilitation were similar (mean 3.42, SD 0.55 each), whereas direct instruction was rated lower (mean 2.88, SD 0.92). Open-ended remarks described links between theory and embodied experience and noted practical challenges.

Conclusions: This study used an early, optional format; the results showed that brief, contrastive VR exposures paired with scaffolded inquiry and a guided debrief were perceived as pedagogically valuable for exploring foundational physiological concepts, while also highlighting feasibility and logistical considerations for routine teaching. Findings are preliminary and reflect session-level perceptions from a small, self-selected sample; nevertheless, they suggest that structured, low-stakes VR may serve as a feasible supplemental strategy in first-semester nursing education, with implications for potential scalability.

Introduction

Background

Contemporary educational paradigms increasingly emphasize the need for immersive, interactive learning environments that integrate theoretical instruction with practical, hands-on experiences, grounded in educational theory and supported by institutional pedagogical frameworks [1-4]. In undergraduate nursing, where foundational concepts about physiology and patient care must be internalized early, there is a growing interest in introducing virtual reality (VR) early in the curriculum as an

XSL•FO
RenderX

optional, low-stakes complement to core coursework to spark engagement and support conceptual understanding in the first semester [5].

A growing evidence base suggests that VR can enhance learning by providing immersive, repeatable, and safe experiences that bridge abstract concepts and embodied understanding. Meta-analyses in nursing education have reported positive effects on theoretical knowledge, technical skills, self-confidence, and learner satisfaction when VR is integrated with attention to design features and instructional support [6-8]. At the same time, findings are not uniform: outcomes vary by intervention design and outcome type, and some studies note that while presence increases, learning can suffer when cognitive load is high or scaffolding is insufficient [5,9,10]. Practical considerations, such as cybersickness risks influenced by exposure duration, content, and locomotion, also warrant attention when working with first-time users [11].

There is limited evidence on how brief, optional VR experiences can be used with first-semester nursing students as experiential learning strategies to support understanding of foundational nursing concepts, outside of mandatory coursework or full-scale simulations. Additionally, little is known about students' and teachers' perceptions of VR as a low-stakes, supplemental learning strategy introduced early in nursing education. Examining these experiences can provide important insight into the pedagogical value and scalability of VR-enhanced learning within the formal nursing curriculum. Reports frequently emphasize usability or novelty yet underdescribe how short VR exposures are pedagogically integrated to connect conceptual content (eg, autonomic physiology) with immediate experiences and collaborative sensemaking [5,10].

To guide a purposefully designed, concise activity, we drew on education 4.0 (learner-centered, experience-driven, and digitally supported learning); constructive alignment (coherence among intended learning outcomes, teaching and learning activities, and assessment); and the community of inquiry (CoI) framework (cognitive, social, and teaching presence) [12-18]. Framing VR as one tool within an aligned pedagogical design helps ensure that brief exposures are structured to foster inquiry, link embodied responses to concepts, and support facilitated reflection.

To address these gaps, we implemented and evaluated a brief, optional, VR-enhanced workshop offered outside mandatory coursework in first-semester nursing education. The model combined short headset exposures designed to elicit contrasting autonomic responses, peer practice of vital-sign measurement to support observation and discussion, small-group synthesis, and a guided debrief aligned to the CoI practical inquiry cycle. We describe the implementation and examine students' and teachers' experiences, focusing on students' perceptions of cognitive, social, and teaching presence as indicators of the perceived learning environment [15-17].

Objective

This study explores students' and teachers' experiences of a brief, optional VR-enhanced workshop offered outside mandatory coursework in first-semester nursing education and described students' perceptions of cognitive, social, and teaching presence.

Methods

Design and Reporting

This cross-sectional study evaluated an optional, VR-enhanced workshop using postworkshop surveys (Likert-type items and open-ended responses). No behavioral observation checklists were used. Reporting follows STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidance for cross-sectional studies [19].

Setting, Participants, and Recruitment

The activity took place at a Swedish public university (south central region). All first-semester nursing students (N=134) were invited to participate via announcements on the online classroom platform and brief in-class invitations. Registration remained open for one week, and 16 (11.9%) students who expressed interest received a confirmation message securing their place in the workshop. Participation was voluntary and outside mandatory coursework. In addition, 3 nursing teachers participated across all workshop phases and provided brief reflections. Library makerspace staff co-facilitated implementation (roles are detailed in subsequent sections) but were not included in the teacher feedback items.

Workshop

This optional, supplemental, VR-enhanced experiential learning activity (distinct from a clinical simulation scenario) was offered alongside the first-semester curriculum and was not included in required assessments or mandatory components. Students were divided into 2 groups of 8 for workflow and logistical reasons (nonrandom allocation). Each group completed one VR module, either a short roller-coaster exposure (sympathetic arousal) or a short guided meditation (parasympathetic engagement), followed by inquiry tasks and a guided debrief (Table 1). The workshop was implemented as an optional addition to existing teaching (ie, not part of the school's required simulation infrastructure) to explore perceived experiences with a concise, aligned model.

Table . Time structure of the workshop.

Component of the workshop	Time (min)
Virtual reality exposure and peer vital-sign practice	60
Working on answering the given questions and preparing a PowerPoint presentation	75
Group presentations and reflection	45

XSL•FO
RenderX

Implementation Roles (Contextual)

The workshop was co-designed and co-facilitated by 2 units: nursing teachers (pedagogical design, alignment with first-semester concepts, and facilitation of the debrief and links to physiology) and university library makerspace staff (readiness and comfort protocols for first-time VR use; headset onboarding; hygiene, sanitation, and logistics; and facilitation of information-seeking and source evaluation during the inquiry task). This cross-unit collaboration supported delivery; no evaluation of collaboration effects (eg, feasibility, process outcomes, or comparative effectiveness) was undertaken, and collaboration was not a study outcome.

VR Exposures and Rationale

We selected brief headset exposures to contrast autonomic activation states: (1) sympathetic activation via an approximately 4-minute Epic Roller Coasters track and (2) parasympathetic engagement via an approximately 5- to 6-minute TRIPP guided meditation, primarily to support conceptual understanding of autonomic physiology and secondarily to maintain comfort and accessibility for first-time users [20,21]. Evidence summarized in prior reviews indicates that cybersickness risk is associated with exposure duration, visual stimulation, and locomotion and content; comfort-oriented, shorter sessions are commonly recommended for first-time users [11,22].

Vital-Sign Practice Procedure

Before headset use, each student had resting baseline values recorded (heart rate, blood pressure, respiratory rate, oxygen saturation, and tympanic temperature) using standard training instruments in the student practice ward. To minimize movement artifact and measurement reactivity, spot-checks were obtained immediately after the VR exposure (not during). These measurements were intended to support observations, understanding of sympathetic and parasympathetic responses, and postexperience discussion, rather than research-grade physiological inference; no continuous monitoring was performed, and readings were not designed to isolate specific organ-system mechanisms.

Grouping and Sequence

Two groups of 8 proceeded in parallel (roller coaster *or* meditation). Assigning 1 module per group supported the single-session timebox, comfort for first-time users, and a contrastive learning design that allowed cross-group comparison during synthesis and debrief. Students could reference their own baseline and immediate postexposure readings (eg, heart rate, blood pressure, and respiratory rate) in slides and discussion to illustrate sympathetic vs parasympathetic patterns.

Inquiry Tasks and Presentation (CoI Aligned)

Small groups completed 3 tasks designed to link embodied responses to conceptual understanding and to support the CoI practical inquiry cycle [15,16].

First, explain observations with evidence—locate and use credible sources (textbooks, peer-reviewed literature, and institutional resources) to interpret observed changes consistent with sympathetic vs parasympathetic mechanisms.

Second, synthesize a brief minilesson—prepare a short slide deck that links observations and theory (autonomic physiology; cardiovascular regulation), applies source appraisal, and communicates clearly to peers. Students could optionally include their own heart rate, blood pressure, and respiratory rate comparisons; content on heart dynamics, signaling pathways, and energy metabolism was addressed via literature-based synthesis.

Third, present and debrief (guided)—deliver the minilesson and then participate in a guided debrief aligned with CoI prompts (eg, triggering event, exploration and integration, and bounded resolution). Facilitation emphasized guided reflection and feedback tailored to the goals of the workshop.

Scaffolds: Prompts and Rubrics

Instructors used structured supports to scaffold the activity. The observation log rubric included baseline vs immediate postexposure readings and salient sensations, along with a brief plain-language interpretation. The source evaluation rubric included authority, accuracy, relevance, and timeliness. The synthesis rubric included claim evidence reasoning, alignment to the learning goal, and clarity for peers. These scaffolds guided observation, evidence appraisal, and coherent explanation and were not graded assessments.

The source evaluation rubric included authority, accuracy, relevance, and timeliness. The synthesis rubric included claim evidence reasoning, alignment to the learning goal, and clarity for peers. These scaffolds guided observation, evidence appraisal, and coherent explanation and were not graded assessments.

Data Collection and Measures (Combined)

Students completed an anonymous postworkshop survey with 4 components.

First, the survey collected demographic data on age, gender, and prior VR headset experience.

Second, the survey included 7 VR-perception items that were workshop-specific and targeted perceived analysis and exploration, conceptual understanding and engagement, teacher support, relevance, and the value of learning new technology. These items were tailored to this workshop and were not intended as a validated general instrument; therefore, reliability statistics were not reported for this subscale.

Third, the CoI instrument (34 items) was used and its wording was adapted minimally to the in-person, single-session context (eg, replacing “course” with “workshop activity”) while preserving full coverage of the constructs (cognitive, social, and teaching presence). Given the small sample, we did not estimate reliability in this study; we relied on prior validation literature [15,16].

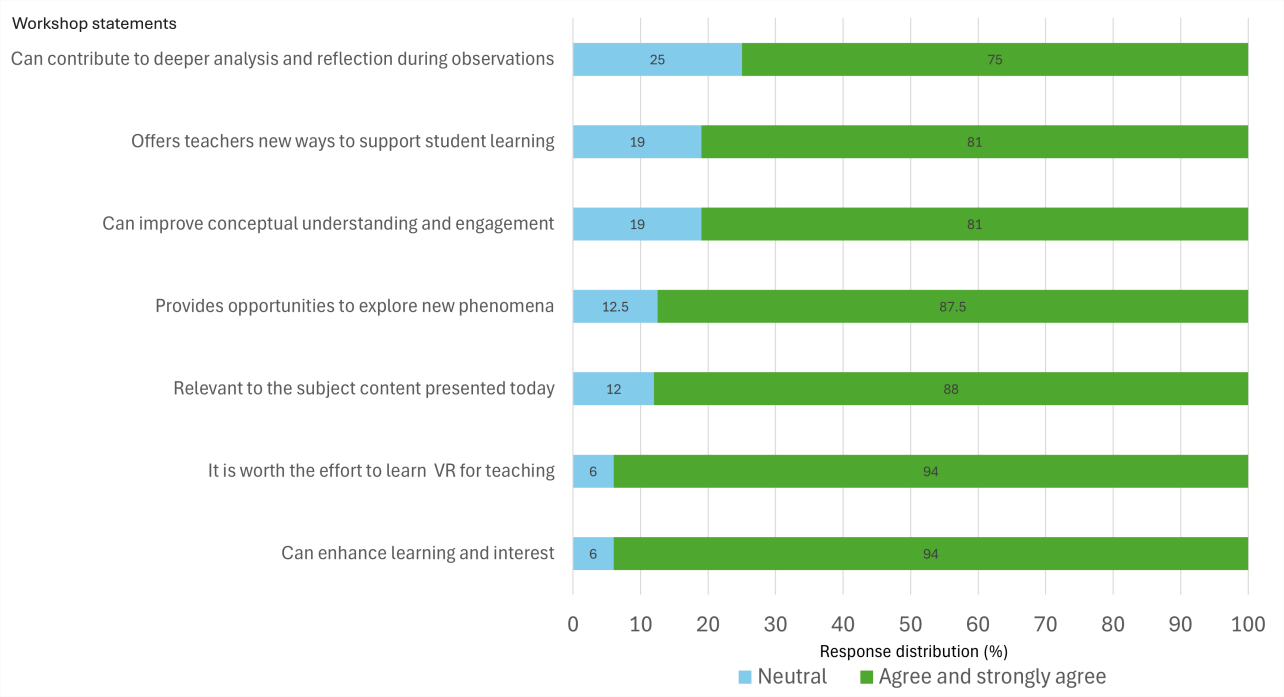
Fourth, the survey included 2 open-ended questions addressing challenges, barriers, and opportunities for learning with VR, including reflections that could reference sensations experienced. Teachers (nursing teachers) provided brief reflections, whereas makerspace staff co-facilitated implementation but did not complete teacher items.

XSL•FO
RenderX

Ethical Considerations

Participation was voluntary with written informed consent obtained from all participants. Responses were anonymized to protect privacy and confidentiality. Formal ethics review was not required for this type of educational research at our institution and no sensitive personal data were collected [23]. No compensation was provided to participants.

Analysis



Quantitative data were summarized descriptively (no inferential statistics were performed). The 7-item workshop-specific perceptions were reported as distributions; no reliability statistics were calculated. For the CoI instrument, we reported subscale and total scores descriptively and relied on prior validation literature rather than estimating reliability in this small sample. Open-ended responses underwent summative content analysis (2 coders independently open coded the data and reconciled differences through discussion; categories were not assumed to be mutually exclusive) [24].

Results

Overview of Outcomes

Table 2 summarizes students' CoI scores (teaching, social, and cognitive presence and their subdomains); Figure 1 shows agree and strongly agree distributions for the 7-item VR-perception statements, sorted from highest to lowest.

Figure 1. Nursing student ratings concerning using virtual reality (VR) in education.

Table . Mean score of the community of inquiry (CoI) survey instrument (n=16).

CoI survey elements	Scores, mean (SD)
Teaching presence	3.28 (0.57)
Design and organization	3.42 (0.55)
Facilitation	3.42 (0.55)
Direct instruction	2.88 (0.92)
Social presence	3.26 (0.60)
Affective expression	3.04 (0.65)
Open communication	3.35 (0.68)
Group cohesion	3.38 (0.69)
Cognitive presence	3.48 (0.41)
Triggering event	3.58 (0.46)
Exploration	4.48 (0.49)
Integration	3.46 (0.46)
Resolution	3.42 (0.49)
Total score	3.36 (0.44)

Of the students at the nursing school (n=134), 16 (11.9%) signed up to participate. The study included 16 students (mean age 25, SD 5.1; range 20‐38 years), of whom 15 (93.8%) were women. Of the 16 students, 37.5% (n=6) had prior experience using VR headsets. Among these, 2 (12.5%) students had used VR headsets for gaming purposes and 3 (18.8%) students experienced motion sickness or stress during the use of VR. One (6.3%) student did not provide details about their prior experiences with VR. In addition to the students, 3 teachers (mean age 51; SD 10.0, range 43‐62 years; all male) participated in the workshop. Two teachers had previous experience with VR headsets: one had used them on a few occasions and the other had explored both recreational and pedagogical applications of VR.

Of the 16 students, most agreed or strongly agreed that the VR headsets could increase analysis and observation (n=12, 75%), could help with exploring a new phenomenon (n=14, 87.5%), could increase concept knowledge and engagement (n=13, 81.3%), could create new possibilities for teachers to support their students in learning (n=13, 81.3%), and were relevant to use for the topic of the workshop (n=14, 87.5%) and thought it was worth learning a new technology (n=15, 93.8%; Figure 1).

CoI Results

For interpretability, teaching presence reflects design and organization, facilitation, and direct instruction; social presence reflects affective expression, open communication, and group cohesion; and cognitive presence reflects triggering event, exploration, integration, and resolution. Participants' ratings indicated moderately positive perceptions of the workshop's learning environment (Table 2). Within teaching presence, design and organization and facilitation were similar (mean 3.42, SD 0.55 each), whereas direct instruction was lower (mean 2.88, SD 0.92). Social presence averaged 3.26 (SD 0.60), with subdomains ranging from affective expression (mean 3.04, SD 0.65) to group cohesion (mean 3.38, SD 0.69). Cognitive presence had the highest overall mean 3.48 (SD 0.41), with exploration rated highest among its subdomains (mean 4.48, SD 0.49), followed by triggering event (mean 3.58, SD 0.46), integration (mean 3.46, SD 0.46), and resolution (mean 3.42, SD 0.49). Students referenced their own baseline and immediate postexposure readings (eg, heart rate, blood pressure, and respiratory rate) descriptively to illustrate sympathetic versus parasympathetic patterns; these readings were not analyzed as outcomes.

Qualitative Results (Open-Ended Responses)

Overview

As outlined in the Methods section (summative content analysis), we analyzed anonymous, session-specific open-ended comments. A total of 15 (93.8%) of the 16 students and all 3 teachers provided responses (18/19, 94.7% contributors in total). The unit of analysis was the individual comment. Codes were merged into 3 descriptive categories, and the counts reported represent the number of unique contributors per category. Categories were not mutually exclusive, and the quotations included are illustrative rather than exhaustive [24].

Challenges to VR Use

Participants (9/18, 50%) noted cybersickness and physiological discomfort, headset comfort and time burden, access, logistical, and technical issues, and unfamiliarity and the learning curve.

> *What I can think of is that one can easily become nauseous, and that leads to difficulty concentrating.* [Participant 2402]
>
> *Overall experience can be time-consuming.* [Participant 2403]
>
> *Technical issues. Digital literacy is required in the teacher competency.* [Participant 2419]
>
> *Everyone is not familiar with the technology.* [Participant 2415]

XSL•FO
RenderX

Opportunities for Learning

Students and teachers (16/18, 88.9%) highlighted visualization and immersion to aid understanding and recall, stronger links between theory and observed autonomic responses, low-stakes practice, and a structured debrief that supported collaborative sensemaking.

> *I could experience the connection between theory and practice.* [Participant 2415]
>
> *It allows for your senses to be used in other ways with VR which allows for learning in new ways.* [Participant 2407]
>
> *To experience something and the symptoms that arise with it makes it easier to remember in the learning process.* [Participant 2416]
>
> *To mix learning methods gives you a greater understanding and a wider picture.* [Participant 2411]

Feasibility and Logistics

Practical considerations according to participants (5/18, 27.8%) included equipment availability, onboarding, hygiene, sanitation, and fit adjustments, occasional software and hardware restarts, and scheduling.

> *Technical aspects need to work, both software and hardware.* [Participant 2418]
>
> *Students need guidance to find the right levels where they do not get caught in technical details.* [Participant 2417]
>
> *There might be a need to educate the students in VR-basics.* [Participant 2406]

Immediate sensations (eg, nausea, dizziness, and stress) were self-reported by students during the guided debrief and/or the open-ended survey; vital-sign values were not displayed in-headset.

Interpretation

These brief comments help contextualize the session-level experiences but do not provide evidence of longer-term learning or engagement. The counts are descriptive, and no claims of thematic saturation are made, consistent with STROBE guidance for transparent reporting in cross-sectional studies [19].

Link to Cognitive Presence

The qualitative category “opportunities for learning” (16/18, 88.9%) aligns with several components of cognitive presence. Students’ noticing was primarily subjective during exposure and later referenced to postexposure spot-check readings in the debrief, which together reflect CoI triggering events. Their emphasis on visualization, immersion, and linking theory to physiological responses corresponds to exploration, which also received the highest quantitative subdomain score (mean 4.48, SD 0.49). References to small-group synthesis activities and the guided debrief illustrate integration, as students worked to make sense of information across sources. Comments referring to feasibility constraints and the brief scope of the workshop help explain why resolution was rated lower than exploration (mean 3.42, SD 0.49 vs mean 4.48, SD 0.49), although it remained moderate overall. Together, the open-ended responses complement and contextualize the quantitative profile of cognitive presence while remaining descriptive and limited to session-level experiences.

Instructor Observations

Instructors noted that the format enabled students to observe VR-elicited physiological responses and link these observations to autonomic physiology concepts during the group debrief. These impressions are limited to the session; given the brief, individual VR exposure and the supplemental nature of the workshop, the study does not provide evidence for sustained changes in active or reflective learning or overall engagement. Terms such as “personal” or “meaningful” engagement were not measured. Peer vital-sign measurements were used to facilitate discussion and illustrate concepts (not to evaluate learning outcomes).

Discussion

Principal Findings

This study explored students’ and teachers’ experiences with a brief, optional, VR-enhanced workshop introduced outside mandatory coursework in first-semester nursing education. Students perceived the activity as pedagogically valuable for linking autonomic physiology to embodied experience and for exploration within the learning environment. Interpreted through the CoI framework, the overall profile suggested moderately positive perceptions, with the strongest pattern in cognitive presence: exploration. That pattern is consistent with short, inquiry-driven designs that prompt noticing, questioning, and sensemaking during and after exposure [15,16]. In doing so, this study addresses the identified gap by showing how a brief, optional, low-stakes VR exposure can be positioned early in the curriculum and by documenting students’ and teachers’ perceptions of its pedagogical value and perceived feasibility, with implications for potential scalability as a supplemental strategy. These results reflect session-level perceptions during the workshop’s collaborative elements (peer readings, small-group synthesis and presentations, and guided debrief) and should be interpreted cautiously given the brief, optional, single-session design and small sample (n=16); the study did not assess longer-term changes in engagement or learning.

What the Findings Contribute

A central contribution of this work is the demonstration of a low-stakes, early-semester format in which students experience contrasting autonomic states themselves via a short roller-coaster exposure (sympathetic arousal) and a short guided meditation (parasympathetic engagement) and then interpret those experiences through peer discussion, literature-informed minilessons, and a guided debrief. This sequence appears well-suited to catalyzing curiosity (CoI “triggering event” to subsequent “exploration”) and to making abstract physiological concepts more tangible early in the curriculum [15,16]. The optional nature and the brief duration likely reduced performance pressure while preserving focus on conceptual understanding and engagement, which helps explain the salience of exploration even in a single session. Students’ noticing was primarily subjective during exposure (eg, feelings of arousal or

XSL•FO
RenderX

relaxation) and was later referenced to postexposure spot-check readings during the guided debrief and minilessons, providing concrete anchors for interpretation.

Positioned against the broader VR literature, these session-level perceptions align with findings that VR can enhance learning, particularly motivation, satisfaction, knowledge, and skills, when instructional design and scaffolding are explicit [5-8,25]. At the same time, they are consistent with evidence that presence alone does not guarantee learning and that insufficient scaffolding can increase cognitive load and dampen outcomes [5,9]. Our brief, contrastive exposure format with a structured debrief addresses that design dependence by pairing immersive moments with meaning-making activities rather than treating VR as a standalone novelty.

Interpretation in Context (Education 4.0, Constructive Alignment, and CoI)

The workshop design drew on education 4.0 as a high-level orientation to learner-centered, experience-driven, and digitally supported learning, and on constructive alignment to ensure coherence among intended learning outcomes, teaching and learning activities, and reflection [12-14,18]. Notably, vital sign values were not displayed in-headset; students' "triggering events" arose from subjective sensations during exposure and subsequent reference to postexposure spot checks in the debrief. In practical terms, alignment was enacted by contrastive exposures that instantiate target concepts (autonomic arousal vs relaxation), scaffolded inquiry that connects observations to theory (minilessons with source appraisal), and a brief guided debrief aligned with CoI (cognitive, social, and teaching presence) to support sensemaking and closure [15,16]. The study did not conduct competency assessments and does not claim competence gains; rather, it offers exploratory evidence that a concise, optional format can be perceived as pedagogically valuable and feasible for early supplemental use.

Implementation Considerations

Students' reflections and facilitator notes highlighted pragmatic factors important for routine teaching: headset fit and hygiene protocols, onboarding time for first-time users, and occasional software and hardware restarts. Such start-up frictions are common when integrating immersive devices and should be planned for in scheduling and staffing [5]. The brief contrastive design also served a comfort and accessibility function (limited headset time and seated options), which is advisable given that cybersickness risk is associated with exposure duration, visual stimulation, and locomotion; carefully shorter, comfort-oriented sessions are appropriate for novices [11,22].

Implications and Future Recommendations

The findings of this study suggest several practical implications and directions for future research. Positioning early integration of VR as an optional, low-stakes supplement may be beneficial. Offering brief, clearly scaffolded experiences in the first semester may help to prime curiosity and anchor foundational physiology in embodied experience [5,6].

In addition, using contrastive exposures to make mechanistic contrasts vivid (eg, sympathetic vs parasympathetic) and following these with a guided debrief that traces CoI's practical inquiry cycle from triggering events to bounded resolution may support learning [15,16].

Scaffolding with simple tools (observation logs and source evaluation and synthesis rubrics) allows students to produce evidence-informed explanations without adding grading burden [12,13].

Planning for logistics and comfort includes onboarding, sanitation, fit checks, and rapid troubleshooting, and exposures should be kept brief for first-time users [11,22].

Research next steps include moving beyond session-level perceptions to comparative and mixed methods designs that examine knowledge retention, reflective writing quality, and observational rubrics, as well as assessing accessibility (nonheadset alternatives) and scalability (equipment and time models) across cohorts [7,9,25].

Limitations

This study has several limitations that should be considered when interpreting the findings. First, the activity was optional, single-session, and conducted in a single institution with a small, self-selected sample (n=16), which limits generalizability and precludes inference about longer-term effects. Second, outcomes relied on postsession self-report (VR-perception items and the CoI instrument) without objective educational performance measures, comparators, or follow-up; findings therefore reflect session-level perceptions rather than effectiveness or competence.

Third, vital sign readings (eg, heart rate, blood pressure, and respiratory rate) were collected only as instructional aids to support observation and discussion. In this study, we recorded a resting baseline before exposure and spot-checks immediately after exposure; we did not collect data during exposure or conduct continuous physiological monitoring, and values were obtained with standard training instruments by peers rather than research-grade devices. Consequently, these readings are not suitable for physiological inference, characterization of within-session dynamics, or clean separation of phenomena such as anticipatory arousal. Immediate sensations (eg, nausea, dizziness, and stress) were self-reported during the guided debrief and/or in open-ended survey responses and were not systematically assessed with a validated instrument.

Fourth, the 7-item VR-perception set was tailored to this workshop and was not intended as a validated, generalizable scale; therefore, we do not report reliability for this set. For the CoI instrument, we adapted wording minimally to fit an in-person, single-session context, but given the small sample, we did not estimate reliability in this study and instead relied on prior validation evidence reported elsewhere. Finally, equipment and logistical factors and cross-unit collaboration supported implementation but were not evaluated as outcomes.

Taken together, these factors indicate that results should be interpreted as exploratory evidence about perceived learning environment and feasibility for an early, optional, low-stakes VR activity; they do not demonstrate objective learning gains or competency development. Directions for addressing these

XSL•FO
RenderX

constraints (eg, comparative designs, larger samples, objective outcomes, structured measures of discomfort, and continuous physiological monitoring) are outlined in the Implications and Future Recommendations section.

Conclusions

A brief optional VR workshop introduced early in nursing education can provide low-stakes, embodied experiences that students perceive as helpful for exploring foundational physiological concepts. When paired with scaffolded inquiry and a guided debrief aligned with CoI, short exposures can prompt curiosity and sensemaking within the formal curriculum, offering a practical, scalable supplement to the required coursework [5,15].

Acknowledgments

The authors would like to express their sincere gratitude to the staff at Clinicum, Campus Norrköping, for their invaluable support and assistance throughout the entire day of the workshop. The authors also acknowledge Peter Johansson, Ghassan Mourad, and Johan Lundgren for their valuable contributions in developing this study.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Data Availability

The datasets used and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

MW, NFC, and LK contributed to the conceptualization of the pedagogical workshop. Data curation was performed by MW and LK. Methodology was developed by MW, NFC, and LK. Original draft preparation was conducted by NFC and MW. Writing, review, and editing were carried out by LK.

Abstract

Background: As patient populations become increasingly diverse, nurses must develop cultural competence to provide effective and equitable care.

Objective: This study aims to examine the predictors of cultural competence among nurses, specifically investigating the roles of digital health literacy (DHL) and cultural intelligence, while also assessing how demographic factors, competence levels, and DHL relate to culturally competent behaviors.

Methods: A cross-sectional study was conducted with 296 nurses at a private hospital in Saudi Arabia. Data were collected using validated instruments to assess DHL, cultural intelligence, and cultural competence. Descriptive statistics, independent *t* tests, Pearson correlations, and hierarchical multiple linear regression analyses were performed using SPSS (IBM Corp) to evaluate the associations and predictors of cultural competence.

Results: In a sample of 296 nurses, cultural intelligence was observed at a moderate level, present in 35.8% (n=106) of participants. Conversely, more than half of the participants (n=158, 53.4%) exhibited low DHL. The majority of the nurses (n=195, 65.9%) demonstrated moderate cultural competence. Education was the only demographic factor significantly associated with cultural competence, with nurses holding a Bachelor of Science degree scoring higher than those with a diploma (P=.003). Furthermore, cultural intelligence and DHL each showed a strong positive correlation with cultural competence (P<.001). Hierarchical regression analyses indicated that both cultural intelligence (β=.427; P<.001) and DHL (β=.315; P<.001) were significant predictors of cultural competence, jointly explaining 47.7% of the variance (adjusted R^2=0.460; P<.001). Nationality also emerged as a significant predictor (β=.105; P=.03), whereas other demographic variables were not statistically significant. Cultural intelligence accounted for the largest proportion of explained variance (ΔR^2=0.375), followed by DHL (ΔR^2=0.051).

Conclusions: Cultural competence among nurses is predominantly influenced by cultural intelligence and DHL, rather than by most demographic variables. Consequently, enhancing DHL and cultural intelligence may strengthen culturally competent practice. It is recommended that targeted educational and professional development interventions be implemented to elevate competence and support high-quality patient care across diverse health care settings.

(JMIR Nursing 2026;9:e97334) doi:10.2196/97334

KEYWORDS

cultural competency; cultural intelligence; digital health literacy; DHL; nurses; Saudi Arabia

Introduction

In an increasingly globalized health care environment, cultural competence has become an essential component of high-quality nursing practice. It enables nurses to deliver care that respects patients' cultural and religious values, beliefs, and practices, thereby improving patient outcomes, satisfaction, and health care equity [1]. In addition to ethnicity and language sensitivity, culturally competent nursing care requires sensitivity to patients' religious beliefs and practices, particularly in multicultural health care settings. Religious values may influence health care decisions regarding informed consent, end-of-life care, organ donation, reproductive health, dietary restrictions, and acceptance of specific medical treatments [2-4]. Previous studies have emphasized that culturally responsive care requires nurses to understand and respect patients' religious and spiritual beliefs, including those associated with Islam, Judaism, Christianity, and other faith traditions, while maintaining ethical and

XSL•FO
RenderX

patient-centered practice [2-4]. These findings further highlight that cultural competence extends beyond communication skills to include religious and spiritual awareness in clinical decision-making [2].

As health care systems become more culturally diverse, nurses must possess the knowledge, skills, and attitudes necessary to communicate effectively and provide culturally responsive care. This includes recognizing how cultural and religious diversity influences patients' preferences, expectations, and health care decisions. Recent international literature also highlights that workforce diversity, intercultural communication, and technology-enhanced health care are increasingly shaping culturally competent nursing practice [5].

Cultural competence is influenced by multiple individual and professional factors, including digital health literacy (DHL) and cultural intelligence [6]. DHL, defined as the ability to search for, evaluate, and apply health information using digital technologies, has become an essential competency for evidence-based nursing practice in technology-driven health care systems [7,8]. Emerging evidence further suggests that digital technologies, including AI-supported educational tools and culturally adapted digital resources, can strengthen nurses' clinical decision-making and promote culturally competent care. Likewise, cultural intelligence, the capability to function effectively across different cultural contexts, enables nurses to adapt their communication and care to the needs of culturally diverse patients [9,10].

International studies have demonstrated that structured educational interventions incorporating experiential learning, intercultural communication, reflective practice, and technology-enhanced learning improve both cultural intelligence and cultural competence among nursing students and practicing nurses [9,11,12]. In addition, nurses with higher DHL are more likely to use evidence-based clinical guidelines, patient education resources, and culturally appropriate digital tools to deliver individualized care [13,14]. Park and Nahm [15] further reported that nurses' use of point-of-care technologies is associated with greater confidence in clinical decision-making and participation in culturally sensitive evidence-based practice.

The importance of these competencies is particularly evident in Saudi Arabia, where a rapidly evolving health care system serves an increasingly multicultural patient population [5]. Previous studies conducted in Saudi Arabia have identified gaps in cultural competence among both nursing students and practicing nurses, largely attributed to limited exposure to transcultural education and culturally sensitive communication training [5,16]. Hamdan Alshammari and Alboliteeh [6] further emphasized that professional competence and cultural competence are closely interconnected, suggesting that both education and clinical experience contribute to culturally congruent nursing care.

Demographic characteristics such as age, educational level, and years of clinical experience may further influence cultural competence, DHL, and cultural intelligence [13,17]. Nurses with greater clinical experience often demonstrate stronger cultural competence due to prolonged exposure to diverse patient populations, whereas younger nurses may possess stronger DHL but require additional support in translating these digital skills into culturally responsive clinical practice [7,18-20].

Although previous studies have independently demonstrated that DHL and cultural intelligence contribute to cultural competence, most research has focused on educational interventions or specific dimensions of cultural competence, whereas limited empirical evidence has examined how DHL and cultural intelligence jointly predict cultural competence among practicing nurses, particularly within the Saudi health care context [1,8]. Furthermore, the extent to which demographic characteristics contribute to cultural competence alongside these factors remains insufficiently explored [6,14]. Addressing this gap may inform educational strategies and workforce development initiatives to strengthen culturally competent nursing care in increasingly diverse health care settings.

Therefore, the purpose of this study was to investigate the predictors of cultural competence among nurses by examining the roles of DHL and cultural intelligence while controlling for demographic variables and competence levels.

Methods

Design and Setting

A cross-sectional design was used for this study. The research was conducted in a private hospital situated in the Eastern region of Saudi Arabia. Registered nurses from various clinical units, including emergency, intensive care, medical-surgical, and outpatient departments, were invited to participate. These diverse clinical settings offered a suitable context for investigating DHL, cultural intelligence, and cultural competence within the framework of routine nursing practice. This study constitutes an in-depth analysis of an existing dataset previously used to test a structural model of culturally competent behavior. In the current analysis, a multiple regression approach was used to examine the individual predictive effects of DHL, cultural intelligence, and demographic variables on cultural competence behavior.

Participants and Sampling

A convenience sampling method was used to recruit eligible registered nurses. The inclusion criteria specified that participants must be registered nurses engaged in direct patient care with a minimum of 6 months of clinical experience. Nurses occupying primarily administrative or managerial positions were excluded from the study due to their limited direct patient interaction. An a priori power analysis conducted using G*Power (Heinrich Heine University Düsseldorf) determined that a minimum sample size of 222 participants was necessary to identify a small-to-moderate effect size (f^2=0.05) at a significance level of α=.05, with 80% statistical power in a multivariable regression model.

Measures

DHL was evaluated using the eHealth Literacy Scale, an 8-item instrument designed to measure individuals' perceived capacity to locate, assess, and apply online health information. Each item was rated on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree) [21].

XSL•FO
RenderX

Cultural intelligence was measured using the 20-item Cultural Intelligence Scale, which encompasses metacognitive, cognitive, motivational, and behavioral domains. Responses were recorded on a 7-point Likert scale, with values ranging from 1 (strongly disagree) to 7 (strongly agree) [22].

Cultural competence was assessed through an 8-item behavioral scale derived from established instruments measuring cultural competence. The items targeted observable culturally responsive nursing behaviors and were rated on a 5-point scale, where 1 indicated "never" and 5 indicated "always" [23]. In the present study, all instruments exhibited excellent internal consistency reliability, with Cronbach α exceeding 0.95.

Demographic data included age, gender, marital status, education level (diploma vs Bachelor of Science [BSc] in Nursing), specialty, years of experience, and nationality. In Saudi Arabia, a nursing diploma is conferred upon completion of a 2 - to 3-year program at a health institute, whereas a BSc in Nursing requires successful completion of a 4- to 5-year university degree.

Data Collection Procedure

The survey was administered using QuestionPro (QuestionPro Inc) in February 2026. Access was restricted to invited participants via a unique link. Nurses were invited through hospital nursing departments via email and WhatsApp. Of the 411 nurses who viewed the survey, 296 completed it (participation rate of 72.0%). IP address checking and cookies were enabled to prevent duplicate submissions. Incomplete questionnaires were excluded from analysis. Responses completed in less than 1 minute were excluded to ensure data quality.

Ethical Considerations

Ethical approval was secured from the Institutional Review Board of the participating hospital, Dr Sulaiman Al Habib Medical Group (RC26.02.08). Participation in the study was voluntary, and informed consent was obtained prior to the commencement of data collection. No identifiable information was gathered and all responses were treated with confidentiality. Data were stored securely and were accessible solely to the research team. The study complied with the ethical principles delineated in the Declaration of Helsinki.

Data Analysis

Data were analyzed using SPSS (version 22; IBM Corp). Descriptive statistics were computed for demographic variables and study constructs. Categorical variables were summarized using frequencies and percentages, while continuous variables were reported as means and SDs.

Levels of cultural competence, cultural intelligence, and DHL were categorized using percentile-based cutoffs for descriptive purposes. Categories were established as low, moderate, and high through visual binning based on percentile distribution in SPSS. This methodology facilitated the empirical derivation of cutoffs, reflecting the natural distribution of scores within the sample and enabling meaningful interpretation and comparative analysis across constructs.

Independent samples *t* tests were used to explore differences in competence across various demographic groups. Pearson correlation analysis was performed to investigate relationships among the primary study variables. Hierarchical multiple linear regression was conducted to identify predictors of cultural competence. Demographic variables were entered in the first block, cultural intelligence in the second block, and DHL in the final block. Statistical significance was established at $P<.05$.

Prior to regression analysis, all assumptions were rigorously tested. Normality of residuals was assessed using the Shapiro-Wilk test and visual inspection of P-P plots. Linearity was confirmed through scatterplots of standardized residuals against predicted values. Homoscedasticity was assessed via visual inspection of residual plots, and independence of errors was confirmed using the Durbin-Watson statistic, which fell within an acceptable range. All assumptions were met. Multicollinearity was assessed using tolerance values. All tolerance values exceeded 0.10 (ranging from 0.511 to 0.944), indicating no serious multicollinearity among predictors.

Results

Internal consistency was evaluated using Cronbach α for all study scales (N=296). The Cultural Intelligence Scale, consisting of 20 items, exhibited excellent reliability (α=0.969). The eHealth Literacy Scale, comprising 8 items, similarly demonstrated high internal consistency (α=0.959). Likewise, the Cultural Competence Scale, which also included 8 items, reflected strong reliability (α=0.957). The corrected item-total correlations for all scales exceeded 0.65, and the Cronbach α values did not significantly increase upon the deletion of any item, indicating robust homogeneity and stability of the items within each construct.

The study's sample comprised 296 participants, with a predominance of females (n=285, 96.3%), while males constituted only 3.7% (n=11) of the cohort. More than half of the participants were single (n=171, 57.8%), whereas 42.2% (n=125) were married. The majority of respondents held a BSc degree (n=221, 74.7%), while 25.3% (n=75) possessed a diploma qualification. In terms of clinical specialty, the majority were employed in non–critical care unit settings (n=234, 79.1%), with 20.9% (n=62) working in critical care environments. Furthermore, most participants were non-Saudi (n=225, 76.0%), while 24.0% (n=71) identified as Saudi nationals.

The mean age of the participants was 30.36 (SD 5.8) years, with a median age of 29 (IQR 25-34) years and a range spanning 23 to 51 years, indicating a relatively young sample. The average years of professional experience was 4.97 (SD 4.8) years, with a median of 3 (IQR 1-7) years and a range of 1 to 24 years, suggesting moderate variability in clinical experience among participants (Table 1).

Saudi, n (%)	71 (24.0)
Non-Saudi, n (%)	225 (76.0)
Age (years)	
Mean (SD)	30.36 (5.8)
Median (IQR; range)	29 (25-34; 23-51)
Experience (years)	
Mean (SD)	4.97 (4.8)
Median (IQR; range)	3 (1-7; 1-24)

[a]BSc: Bachelor of Science.

The mean cultural competence score among participants was 28.62 (SD 4.2), with the majority, 65.9% (n=195), classified as possessing moderate competence and 34.1% (n=101) exhibiting low competence. Regarding cultural intelligence, the mean score was 85.87 (SD 14.0), with participants relatively evenly distributed across the competency levels: 35.8% (n=106) categorized as moderate, 34.1% (n=101) as low, and 30.1% (n=89) as high. The average DHL score was 33.16 (SD 5.9), indicating that over half of the participants (n=158, 53.4%) were classified as having low DHL, while 18.6% (n=55) fell into the moderate category and 28.0% (n=83) were classified as high. Overall, while cultural competence and cultural intelligence scores were predominantly moderate, a significant proportion of nurses demonstrated low DHL, underscoring a critical area that requires targeted professional development (Table 2).

Table . Levels of cultural competence, cultural intelligence, and digital health literacy of participants (N=296).

Variable and category	Score, mean (SD)	Participants, n (%)
Cultural competence	28.62 (4.2)	
Low (≤27)		101 (34.1)
Moderate (28–32)		195 (65.9)
Cultural intelligence	85.87 (14.0)	
Low (≤81)		101 (34.1)
Moderate (82-96)		106 (35.8)
High (>96)		89 (30.1)
Digital health literacy	33.16 (5.9)	
Low (≤32)		158 (53.4)
Moderate (33-37)		55 (18.6)
High (>37)		83 (28.0)

Independent samples *t* tests were conducted to assess differences in cultural competence across various demographic groups. A statistically significant difference was identified solely in relation to education level. Participants holding a BSc degree (mean 29.06, SD 4.14) exhibited significantly higher competence scores compared to those holding a diploma (mean 27.36, SD 4.40; t_{294}=−3.022; *P*=.003). No statistically significant differences in competence were detected based on gender, marital status, specialty, nationality, age category, or years of experience (all *P*>.05). These findings suggest that educational qualification is the only demographic factor associated with elevated cultural competence scores within this sample (Table 3).

Table . Differences in cultural competence across demographic groups.

Variable and group	Participants, n (%)	Cultural competence score, mean (SD)	*t* test (*df*)	*P* value
Gender			−0.425 (294)	.67
Male	11 (3.7)	28.09 (4.95)

>3	140 (47.3)	28.74 (4.62)		

[a]BSc: Bachelor of Science.

Pearson correlation analysis revealed the presence of strong and statistically significant positive relationships among all study variables. Cultural intelligence exhibited a robust correlation with DHL (*r*=0.694; *P*<.001) and a moderate to strong correlation with cultural competence (*r*=0.637; *P*<.001). Furthermore, DHL showed a strong positive association with cultural competence (*r*=0.610; *P*<.001). These findings suggest that higher levels of cultural intelligence and DHL are associated with higher levels of cultural competence. All correlations were significant at the .01 level (2-tailed), indicating substantial interrelationships among the constructs (Table 4).

The final model accounted for 47.7% of the variance in cultural competence (adjusted R^2=0.460; *P*<.001). After controlling for demographic variables, both cultural intelligence (β=.427; *P*<.001) and DHL (β=.315; *P*<.001) emerged as significant positive predictors of cultural competence. Nationality also reached significance (β=.105; *P*=.03), while age, gender, marital status, education, specialty, and experience did not reach significance in the final model. Cultural intelligence accounted for the largest proportion of explained variance (ΔR^2=0.375), followed by DHL (ΔR^2=0.051). See Table 5 for breakdown by predictor variable and Table 6 for models.

Discussion

Principal Findings

This study examined predictors of cultural competence among nurses, focusing on DHL and cultural intelligence, and explored associations with demographic factors and competence levels. Cultural intelligence was identified at a moderate level. In contrast, over half of the participants demonstrated low DHL. Most nurses (n=195; 65.9%) displayed moderate cultural competence. Education was the only demographic factor significantly associated with cultural competence, with BSc holders scoring higher than diploma holders. Cultural

XSL•FO
RenderX

intelligence and DHL were positively correlated with competence, and hierarchical regression revealed that both significantly predicted cultural competence, explaining a substantial portion of its variance.

The results showed that nurses' cultural intelligence was moderate. This finding is consistent with previous studies reporting moderate levels of cultural intelligence among nursing students and health care professionals [9,10]. Higher levels have been observed among nurse educators, suggesting that professional experience and continuous professional development may enhance cultural intelligence [16]. The moderate levels observed in this study are likely due to a lack of formal education in cultural intelligence and limited opportunities for structured intercultural learning. In Saudi Arabia, nurses are often exposed to culturally diverse patients, which can lay the foundation for intercultural interactions; however, this exposure alone may not be sufficient to develop advanced cultural intelligence without targeted educational programs [1].

More than half of the participants had low DHL, suggesting difficulties accessing, appraising, and applying digital health information. This finding is consistent with previous studies reporting inadequate DHL among nursing students and nurses [7,8]. Other studies have also highlighted considerable variability in DHL and emphasized the need for systematic educational interventions [13]. Conversely, higher levels of DHL have been reported among nurses with higher educational qualifications and professional positions, indicating that educational and workplace factors can positively influence digital competency [14]. Low DHL levels in the current study may be explained by a lack of training in using digital platforms, limited institutional support, and factors such as low confidence, restricted access, and the rapid pace of technological change [15].

Most nurses had moderate levels of cultural competence, consistent with previous studies among practicing nurses and nursing students in Saudi Arabia [1,5]. Moderate levels of cultural competence have commonly been reported in settings with limited formal transcultural nursing education, whereas greater professional experience has been associated with higher levels of competence [6,16]. The findings of this study may be due to a combination of theoretical knowledge gained through education and practical experience with different patients. However, the absence of continuous, structured programs for cultural competence may limit further development toward higher levels of competence [11,12].

Among the demographic variables, education was the only factor that significantly predicted cultural competence, with BSc holders outperforming diploma holders. This finding supports previous evidence suggesting that higher educational attainment is associated with stronger professional and cultural competencies [6,14]. However, previous research has also indicated that clinical experience and continuing professional education may enhance cultural competence regardless of initial educational preparation [1]. The current study's results are likely a reflection of the fact that BSc courses involve more transcultural topics, evidence-based practice, intercultural communication, and digital literacy, which, when combined, improve cultural competence [7,9].

Both cultural intelligence and DHL were positively correlated with cultural competence, suggesting that nurses with high adaptability to diverse cultural settings and strong digital literacy skills exhibit greater cultural competence. This finding is consistent with previous research demonstrating that cognitive-cultural capabilities and digital competencies jointly contribute to culturally responsive nursing practice [9,10,13]. Conceptually, cultural intelligence and DHL represent complementary competencies. Cultural intelligence enables nurses to understand, interpret, and adapt to patients' cultural beliefs, values, and communication styles, whereas DHL equips nurses to locate, evaluate, and apply culturally appropriate health information and digital resources. Together, these competencies facilitate informed clinical decision-making, individualized patient care, and effective communication across diverse cultural contexts. Although technological competence is important, previous studies suggest that digital skills alone are insufficient to ensure culturally competent practice without the motivation and ability to adapt to patients' cultural needs [15]. The results therefore indicate that nurses with high cultural intelligence can decode patients' cultural messages and respond appropriately, while those with high DHL can effectively use digital resources to support culturally competent care [7,8].

Hierarchical regression analysis also showed that cultural intelligence and DHL were significant predictors of cultural competence, accounting for a large proportion of the variance in scores. This finding reinforces previous evidence that cognitive-cultural capabilities and digital competencies are both important determinants of culturally competent nursing practice [9,16]. More importantly, the results support the multidimensional nature of cultural competence, demonstrating that effective culturally competent care depends on both interpersonal adaptability and technology-related competencies. Cultural intelligence facilitates adaptive cross-cultural interactions, whereas DHL enables nurses to integrate evidence-based digital resources into culturally responsive care. Their combined contribution suggests that neither competency alone is sufficient; rather, culturally competent nursing practice emerges from integrating both human-centered and digital capabilities. Nurses with adaptive cultural intelligence and DHL are therefore more likely to implement evidence-based, culturally responsive interventions that improve the quality of patient care [12]. Although these individual competencies explained a substantial proportion of cultural competence, organizational factors such as leadership support, access to culturally appropriate digital resources, and continuing professional development may further strengthen culturally competent practice. Future research should examine these organizational influences using longitudinal and theory-driven study designs [1].

Recommendations

Based on the results of this study, the following recommendations can be made. Nursing education programs should integrate cultural intelligence and DHL into undergraduate curricula and continuing professional

XSL•FO
RenderX

development to strengthen nurses' ability to deliver culturally competent care. Simulation-based intercultural communication training and workshops focusing on culturally sensitive digital health services should also be incorporated to enhance both cultural adaptability and effective use of digital health technologies. Additionally, health care organizations should establish institutional policies that promote equitable access to culturally appropriate digital resources, provide ongoing technical and educational support, and foster culturally inclusive work environments through leadership initiatives. Efforts should also be directed toward improving digital accessibility by addressing barriers such as limited technological confidence, inadequate access to digital resources, and unavailability of linguistically and culturally appropriate digital health information for diverse patient populations.

As AI and digital health technologies become increasingly integrated into health care, future educational and organizational initiatives should explore their role in supporting culturally competent nursing practice, including clinical decision support, culturally tailored patient education, and communication across multicultural health care settings. Strengthening these competencies has the potential to improve health care quality, patient safety, and patient satisfaction. For future studies, longitudinal and mixed-methods research is recommended to provide a more comprehensive understanding of the development of cultural competence over time. Future studies should also investigate additional individual and organizational factors, such as leadership support, organizational culture, digital infrastructure, and access to professional development, which may influence cultural intelligence, DHL, and cultural competence among nurses in Saudi Arabia.

Limitations

Although this study identified significant predictors of cultural competence among nurses, it has some limitations. Data were collected from a single private setting, limiting generalizability, and the cross-sectional design prevents causal inferences. Additionally, reliance on self-reported questionnaires may introduce response bias. Future studies should use larger, more diverse samples, longitudinal designs, and objective measures to strengthen the findings.

Conclusions

This study identified DHL and cultural intelligence as key predictors of nurses' cultural competence. While cultural intelligence was moderate, over half of the participants had low DHL, and most showed moderate competence. Education was the only significant demographic factor, with BSc holders scoring higher. Both cultural intelligence and DHL significantly predicted competence, highlighting the need for health care institutions to provide supportive environments with culturally appropriate resources and technology to enhance culturally competent care.

Abstract

Background: Effective pain and opioid management education remains a persistent challenge in health professions training. Static case studies and lecture-based instruction are widely used but may be insufficient to develop the clinical reasoning and communication skills required in practice. Interactive virtual patient simulations, including those powered by large language models, offer scalable alternatives, but head-to-head comparisons of interactive and static case formats using identical content among interprofessional learner populations remain limited.

Objective: This randomized controlled trial examined whether learner knowledge, quiz performance, and engagement differed when educational case studies were delivered through an interactive, AI-enabled virtual patient format versus a static written format. Because the formats differ in interactivity as well as in their use of AI, the trial was designed to test the effect of an "interactive virtual patient format" rather than to isolate any AI-specific effect.

Methods: Health professional students from medicine, nursing, dentistry, pharmacy, and allied health programs at a US academic health sciences university viewed a 12-minute video on pain management and were then randomized 1:1 to complete either 3 static written case studies or 3 interactive virtual patient case studies using the Figment Learning Labs Virtual Clinic. Case content was identical across conditions; only the delivery format was manipulated. The virtual patient system used an AI-enabled conversational interface (GPT-4o) delivering facilitator-authored case material, including a viewable medical record. Knowledge was assessed preintervention and postintervention using an 8-item test. Case discussion quiz accuracy and learner engagement (17 items) were also measured. Of 74 enrolled participants, 58 (78%) completed all study components and were included in this completer-based analysis. Analyses included a 2×2 mixed ANOVA and 2-tailed independent-sample *t* tests (α=.05).

Results: A significant time (pre-post)×group (interactive vs written) interaction was observed ($F_{1,56}$=4.39; P=.04; partial η^2=0.07), indicating greater knowledge gains in the interactive condition. Participants in the virtual patient group demonstrated higher case discussion quiz accuracy (mean 0.79, SD 0.15) than those in the written case group (mean 0.64, SD 0.11; t_{56}=4.48; P<.001). Agreement scores were significantly higher in the interactive group on 13 of 17 engagement items (P<.05), including items addressing realism, enjoyment, and perceived clinical relevance; because these were uncorrected item-level comparisons, they should be read as supportive rather than definitive.

Conclusions: In this preliminary trial, exposure to interactive virtual patient cases was associated with higher engagement and higher short-term knowledge scores than static written cases. The design cannot isolate the independent contribution of AI, conversational interactivity, or time-on-task; the findings therefore support the value of an interactive virtual patient "format" rather than a distinct AI-specific advantage. Because the analysis was completer-based, featured unexplained attrition, and involved 2 authors who are founders of the company commercializing the platform, independent replication in larger, multi-institutional, and longitudinal samples is needed.

KEYWORDS

virtual patients; AI; large language models; ChatGPT; GPT-4o; interprofessional education; health professions education; simulation-based education; learner engagement; pain management education; randomized controlled trial

Introduction

Background

Effective pain management education, particularly regarding opioid risks, remains a challenge in health professions training. Despite initiatives such as the Pain Core Curriculum [1], critical knowledge gaps persist. Traditional approaches, including lectures, readings, and static case studies, often fall short of building the clinical reasoning skills required to address the complexities of patient-centered pain management [2]. Clinical rotations, while valuable, are constrained by availability, patient safety concerns, limited case exposure, and institutional barriers, leaving many students underprepared for nuanced decision-making in clinical practice [3,4].

Simulation-based learning (SBL) offers a solution, enabling practice, feedback, and skill development in complex encounters [5,6]. However, existing SBL formats involve distinct trade-offs in fidelity, cost, scalability, and standardization. Written cases lack interactivity [7], role-playing may feel artificial or inconsistent [8], laboratory-based simulations can be expensive [3], and standardized patient encounters, while realistic, are resource-intensive and limited in scope [9]. Textbox 1 summarizes the relative strengths and limitations of the major SBL modalities, situating interactive virtual patients within this landscape. Recent simulation research has emphasized the importance of deliberate practice, debriefing, fidelity alignment, cognitive scaffolding, and mastery progression to ensure that simulation produces meaningful learning gains [10-12]. There is a pressing need for innovative, scalable approaches that combine the benefits of simulation with greater efficiency and flexibility.

Textbox 1. Relative strengths and limitations of major simulation-based learning modalities.

Written/static case studies

- Strengths: Low cost, highly standardized, and easy to scale and distribute
- Limitations: No interactivity, limited fidelity, and do not require real-time data gathering or decision-making

Role-play with peers

- Strengths: Interactive and low cost
- Limitations: Variable realism and consistency, dependent on peers' skills and engagement

Manikin-/laboratory-based simulation

- Strengths: High physical fidelity and hands-on procedural practice
- Limitations: High cost and infrastructure requirements, limited availability, and faculty-intensive

Standardized (human) patients

- Strengths: High interpersonal fidelity and realistic communication practice
- Limitations: Resource-intensive, limited scalability, and scheduling constraints

Decision-tree virtual patients:

- Strengths: Standardized, scalable, and interactive within preset branches
- Limitations: Constrained/branching dialogue and can feel scripted

Large language model–based interactive virtual patients (this study)

- Strengths: Scalable, open-ended natural-language interaction, real-time medical record and tool use, and asynchronous access
- Limitations: Potential for model errors/hallucinations, requires guardrails and authoritative source content, and dependent on the quality of case-authoring

Cost and scalability remain critical considerations in simulation. Procedural mastery experiences, while effective, can require substantial infrastructure and faculty investment. For example, mastery learning via virtual reality ultrasound simulation reached competency standards but required an estimated cost exceeding US $600 per trainee [10]. Other work in health professional education demonstrates that simulation-based mastery learning facilitates self-efficacy, authenticity of practice, and transfer to clinical performance when supported by repetition and cognitive frameworks [11].

The distinction between active and passive learning is an important confounder when comparing teaching and learning modalities. Multiple experimental studies demonstrate that

XSL•FO
RenderX

interactive, problem-solving approaches improve learning outcomes and perceived learning more than passive, lecture-based instruction [13]. Students, particularly lower-achieving learners, benefit most from active engagement formats [13]. Earlier controlled trials similarly showed that fostering learner-to-learner interaction increased engagement and observable participation even when learning outcomes were equivalent [14]. Flipped classroom models likewise produce higher achievement, greater engagement, and improved retention compared to traditional didactic instruction [15], and gamified and game-based approaches have been associated with increased motivation and engagement in health professions learners [16]. These findings underscore the need to interpret comparative simulation studies through the lens of active-learning effects in addition to any technological capabilities.

Virtual Patients and Large Language Models

Advances in digital simulation technologies and conversational interfaces have expanded opportunities for scalable, interactive learning environments. Virtual patient simulations can be implemented using a range of technologies, from structured decision-tree architectures to newer conversational systems supported by large language models (LLMs). These systems allow learners to engage in real-time dialogue with simulated patients and explore clinical reasoning processes in ways that more closely resemble clinical encounters [17-19]. LLM-driven clinical cases are increasingly being studied across a variety of educational scenarios [20], and this trial is distinguished by its head-to-head randomized comparison of interactive versus static delivery using identical case content in an interprofessional sample.

The pedagogical promise of LLM-based virtual patients must, however, be weighed against well-documented limitations of the underlying technology. LLMs generate responses probabilistically and can produce fluent but incorrect or fabricated content (“hallucinations”), exhibit pattern-driven or stereotyped responses, and vary across runs [21]. Recent work also indicates that straightforward, LLM-crafted cases are not always as engaging or as cognitively demanding as more complex, real-world cases [21]. These properties have motivated calls for explainable and verifiable AI in clinical and educational applications [22,23] and underscore the need for design safeguards, such as facilitator-authored ground-truth case content, explicit guardrails, and a priori scoring keys, when LLMs are used to deliver instructional material. We describe the specific safeguards used in this study in the “Methods” section.

Aim and Hypotheses

Within this context, this randomized study examined whether learning outcomes differed when educational cases were delivered through interactive virtual patient encounters compared with static written case studies. We hypothesized that, relative to static written cases with identical content, the interactive virtual patient format would be associated with (1) greater pretraining to posttraining knowledge gains, (2) higher case discussion quiz accuracy, and (3) higher learner engagement among health professional students learning about pain and opioid management. Because the 2 formats differ in interactivity as well as in their use of AI, the study was explicitly designed to evaluate the “interactive virtual patient format” as a whole rather than to isolate the unique contribution of AI.

Methods

Study Design

This was a single-center, parallel-group, 1:1 randomized controlled trial comparing 2 case-delivery formats following a common didactic video. The trial is reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (Checklist 1).

Participants

Participants were health professional students enrolled at a US-based academic health sciences university, representing programs in medicine, dentistry, nursing, pharmacy, and allied health. Inclusion criteria required active enrollment in clinical or preclinical coursework. An announcement about the study opportunity was made during an interprofessional course in the spring semester. Participation was voluntary.

Ethics Approval

This study was approved by the Medical University of South Carolina’s Institutional Review Board for the Protection of Human Subjects (Pro00137370). All participants reviewed an online informed consent waiver prior to enrollment. No participant-identifying information was shared with the AI model or retained by the AI provider.

Sample Size and Power

This was a preliminary (pilot-scale) trial intended to estimate effect sizes and establish feasibility; an a priori power analysis was not performed, and the achieved sample size was determined by voluntary enrollment within a single course offering. To contextualize the analyzed sample, a sensitivity analysis (computed in G*Power; Heinrich Heine University Düsseldorf) indicated that 58 completers yielded approximately 80% power at α=.05 to detect a between-within interaction in the medium-to-large range. Results are therefore interpreted as preliminary and hypothesis-generating, and the limitations of the sample size for generalizability are addressed in the “Discussion” section.

Knowledge Assessment

A brief, custom 8-item multiple-choice test was developed by the investigators to assess performance on key learning objectives of the training activity: (1) distinguishing among pain types and definitions, (2) selecting evidence-based pain management strategies, (3) assessing opioid treatment considerations and risks, and (4) identifying disparities in pain management. Question stems were developed, and correct answers were determined by consensus of the investigative team; interrater reliability among the authors was not formally assessed. The test was administered pretraining and posttraining. A full copy of the knowledge assessment is included in Multimedia Appendix 1.

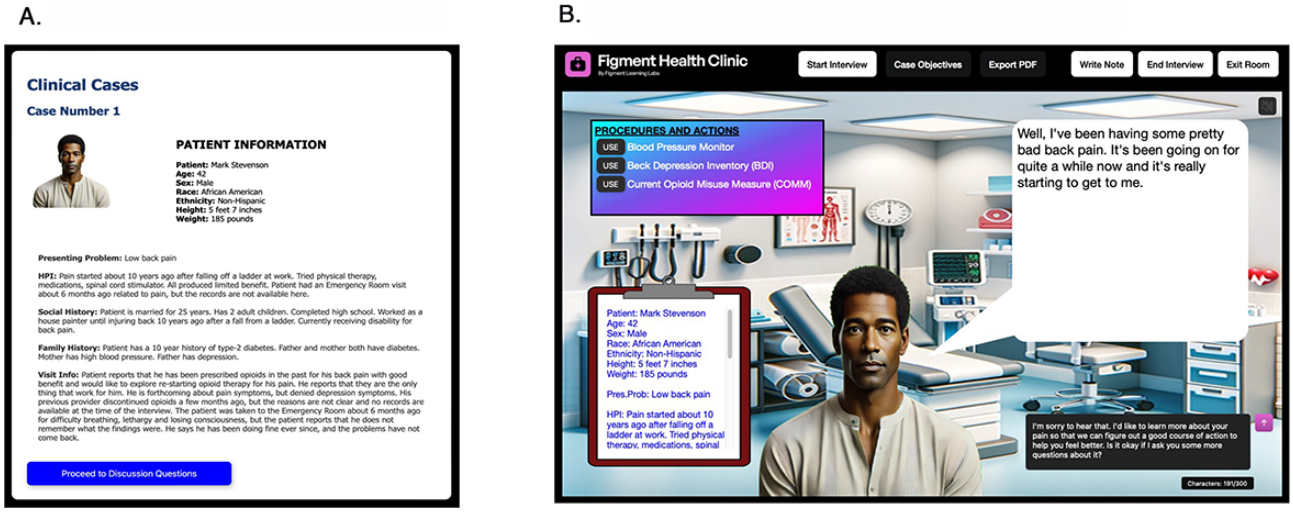
XSL•FO
RenderX

Training Materials

For the didactic portion of this study, participants watched a 12-minute video lecture developed by the authors. The video covered (1) pain definitions, types, and etiologies; (2) empirically supported treatments for each pain type; (3) challenges associated with opioid prescribing identified in the empirical literature; (4) disparities in opioid prescribing; (5) prevalence of chronic pain by race and ethnicity; (6) factors influencing disparities in chronic pain prevalence; and (7) strategies for talking to patients about pain and opioids. All participants watched the same didactic video and were unable to skip any video content.

Randomization and Case Conditions

Participants were randomized 1:1 by the software platform into 1 of 2 groups. Following the didactic video, participants completed either 3 written case studies or 3 interactive case studies. Case content was identical between groups; only the delivery method and the mode of interacting with the case material were manipulated (written cases vs virtual patient cases).



Case Discussion Quiz Questions

In both groups, after completing each of the 3 case studies, participants answered three multiple-choice discussion questions: (1) Is this patient's pain best categorized as nociceptive, neuropathic, both, or neither? (2) Is this patient's pain acute, chronic, or neither? (3) Is this patient a good candidate for opioid therapy? Correct answers were determined a priori by the investigators; the same 3 questions were presented after each case, but correct answers varied as a function of case content. Participants received 1 point for each correct answer and could not return to the case information to answer the questions.

Interactive Virtual Patients and Available Clinical Data

The Figment Learning Labs Virtual Clinic is an online system that allows course facilitators to develop AI-powered interactive cases that students can interview. Importantly, the platform is not a chat-only interface: each case includes a viewable electronic medical record and a set of facilitator-defined assessments, tools, or procedures (eg, vital signs, laboratory results, imaging, medication and allergy lists, and prior treatments) that learners can access during the encounter. Virtual patient avatars (selectable by the facilitator) are animated against a clinic backdrop; the interface includes the patient's medical record, an editable visit/progress note, and a full transcript available afterward for review (Figure 1).

Figure 1. (A) Screenshot of the static, text-based case presentation format. (B) The Figment Learning Labs AI-powered interactive case interface used in this study.

Instructors specify learning objectives for each case along with patient information: name, age, sex, race, ethnicity, height, weight, personality, mood, communication style, chief complaint, history of present illness, social history, family and medical histories, medication list, allergies, and other relevant clinical information. Facilitators also indicate the procedures, tools, or assessments that learners can order, along with the corresponding results that populate the medical record. The record updates in real time when a tool is used, and the AI avatar is instructed on how to respond to each tool. A hidden facilitator instruction field provides more comprehensive case direction that is not visible to the learner. Interviews are online, asynchronous, and interactive, and they can be conducted via voice or text.

Because the clinical "facts" of each case (history, examination findings, laboratory and imaging results, medications, allergies, and the a priori correct discussion answers) are authored by the facilitator rather than generated de novo by the model, the case content available to learners includes the supporting clinical data needed for reasoning, and the determination of correct/incorrect reasoning does not depend on AI-generated facts.

AI System Transparency, Accuracy, and Safeguards

At the beginning of a session, the facilitator-authored patient background information is sent to the OpenAI API as a system-level prompt, together with the activity context and explicit guardrail instructions that constrain the model to the role of the virtual patient and prevent it from supplying

XSL•FO
RenderX

out-of-case clinical information or breaking character. Each learner utterance or tool use is relayed to the API, and the returned response is rendered as the virtual patient's reply. The model also tracks a simulated emotional state, which drives the avatar's facial expression so that learners can respond to verbal and nonverbal cues.

Several design features were intended to support clinical fidelity and reliability. First, the medical record, tool results, and correct discussion answers were fixed and facilitator-authored, so the substantive clinical content and scoring were independent of model variability. Second, guardrail prompts restricted the model to in-case information. Third, no learner-identifying information was shared with or retained by the provider; the API is a stateless instance that does not retain information after a session. We did not implement automated, turn-by-turn verification of every conversational response against the source record; the potential for occasional model errors (eg, hallucinations) and approaches to mitigate them are addressed as a limitation in the "Discussion" section.

AI Model Information

Figment Clinic version 1.0 (Palmetto Innovative Education LLC, doing business as Figment Learning Labs) was used in conjunction with the OpenAI API and the ChatGPT (GPT-4o) model. The model parameters were as follows: temperature=0.7, top_*P*=0.9, frequency_penalty=0.8, presence_penalty=0.8, and max_tokens=500.

Case Study Information

The 3 cases were developed by the authors to represent common encounters with patients presenting with acute, chronic, neuropathic, and nociceptive pain, and each specified the patient's demographic and social context (including age, sex, race, ethnicity, and relevant social history) so that learners encountered contextualized rather than generic patients. All participants received the same 3 cases; only presentation format (written vs interactive) was randomized. Case study details are provided in Multimedia Appendix 1.

Learner Engagement Survey

After completing all training and knowledge tests, participants completed an online engagement survey developed by the authors, consisting of 17 items assessing interface usability and value, engagement and satisfaction, and applicability of the information to real-world scenarios. Items used a 5-point Likert scale (1="strongly disagree" to 5="strongly agree").

Procedures

Study enrollment opened on April 1, 2025, and closed on July 31, 2025. Participants visited the study website, reviewed the informed consent waiver online, completed a demographics form and a baseline knowledge assessment, and were then randomized in a 1:1 ratio by the online system to either written or interactive cases. All participants then viewed the 12-minute educational video on evidence-based pain and opioid management, with an emphasis on care for diverse populations. In the written condition, participants reviewed 3 text vignettes (each with a patient photograph) and answered the discussion questions. In the interactive condition, the same cases were presented as simulated telehealth consultations with AI-powered virtual patients, and participants conducted online interviews to elicit case details (rather than only reading the material in text format) before answering the same discussion questions. After the learning activity, all participants repeated the knowledge test and completed the engagement survey. All sessions were conducted remotely and asynchronously and lasted approximately 45 to 60 minutes.

Statistical Analysis

Knowledge gains were assessed via a 2×2 mixed ANOVA examining knowledge test scores (percent correct) pretraining and posttraining and between groups (written vs interactive). Case discussion accuracy and learner self-report ratings were compared between conditions using 2-tailed independent-sample *t* tests. Where Levene test indicated unequal variances, the Welch correction was applied and the adjusted degrees of freedom were reported. Internal consistency for each instrument was estimated with Cronbach α. Analyses were conducted in SPSS (version 27; IBM Corp), with the critical α set at .05. Because the 17 engagement items were analyzed individually without correction for multiple comparisons, item-level results are interpreted as supportive rather than confirmatory.

Results

Participants and Attrition

A total of 74 participants were enrolled, and 58 (78%) completed all study components and were included in the completer-based analysis. All 16 noncompleters (22%) discontinued before finishing the video training and did not begin the case study portion; reasons for discontinuation were not collected and are unknown. Baseline knowledge test data were available for 63 of the 74 enrolled participants (all 58 completers and 5 of the 16 noncompleters); the degrees of freedom for the baseline comparisons in Table 1 reflect this denominator. There were no significant differences between completers and noncompleters in sex, race, ethnicity, degree program, or age (Table 1), but because the reasons for attrition are unknown, the possibility that unmeasured differences biased the observed group differences cannot be excluded (see "Limitations" section). The overall study procedures are summarized in Figure 2.

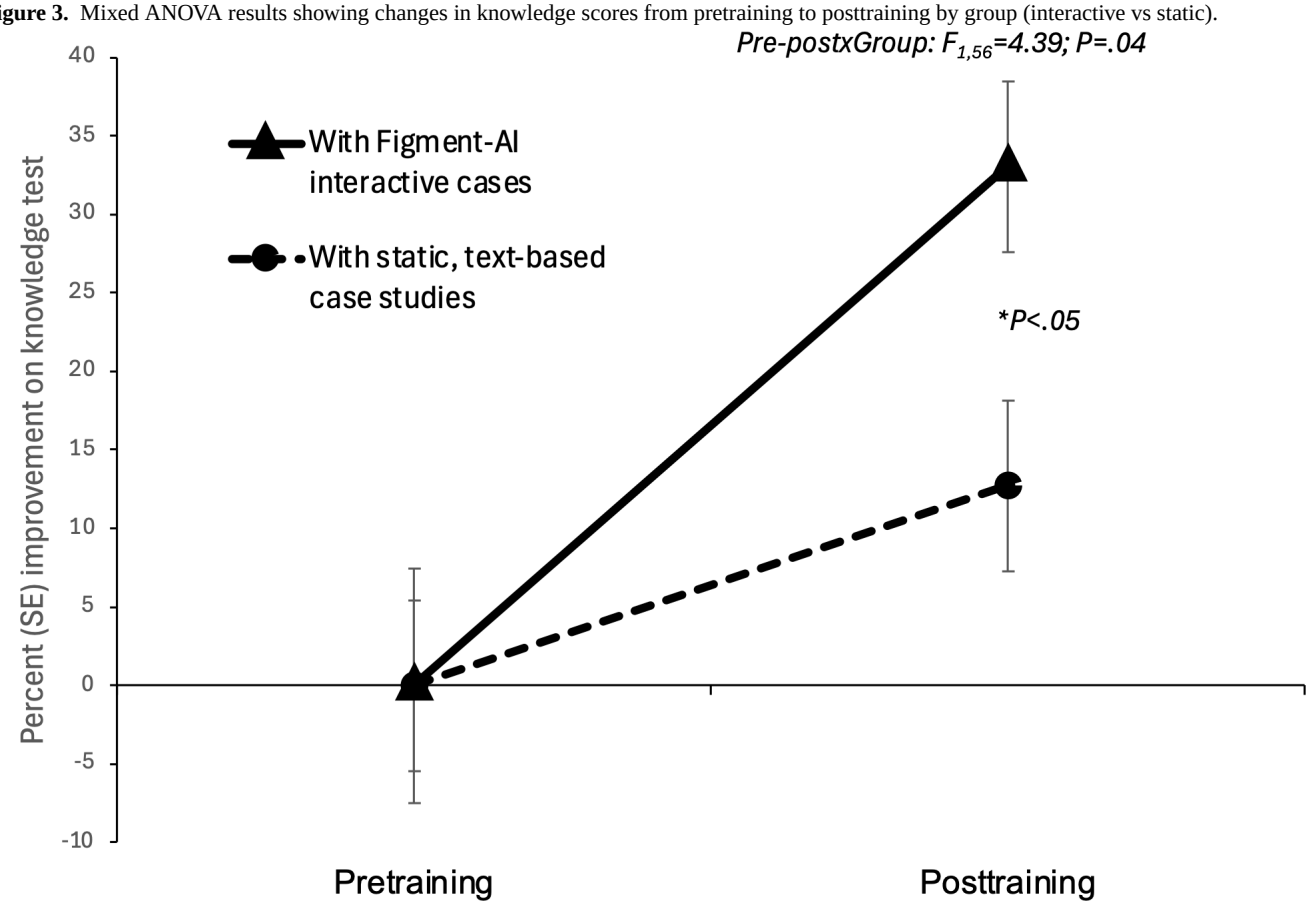
Figure 2. Study procedure diagram.

Among the 58 completers, 16 (28%) were male and 42 (72%) were female; mean age was 26.07 (SD 6.74) years. Self-reported race was White (n=42, 72%), Asian (n=9, 16%), Black (n=5, 9%), and multiracial (n=2, 3%); ethnicity was Hispanic (n=4,



XSL•FO
RenderX

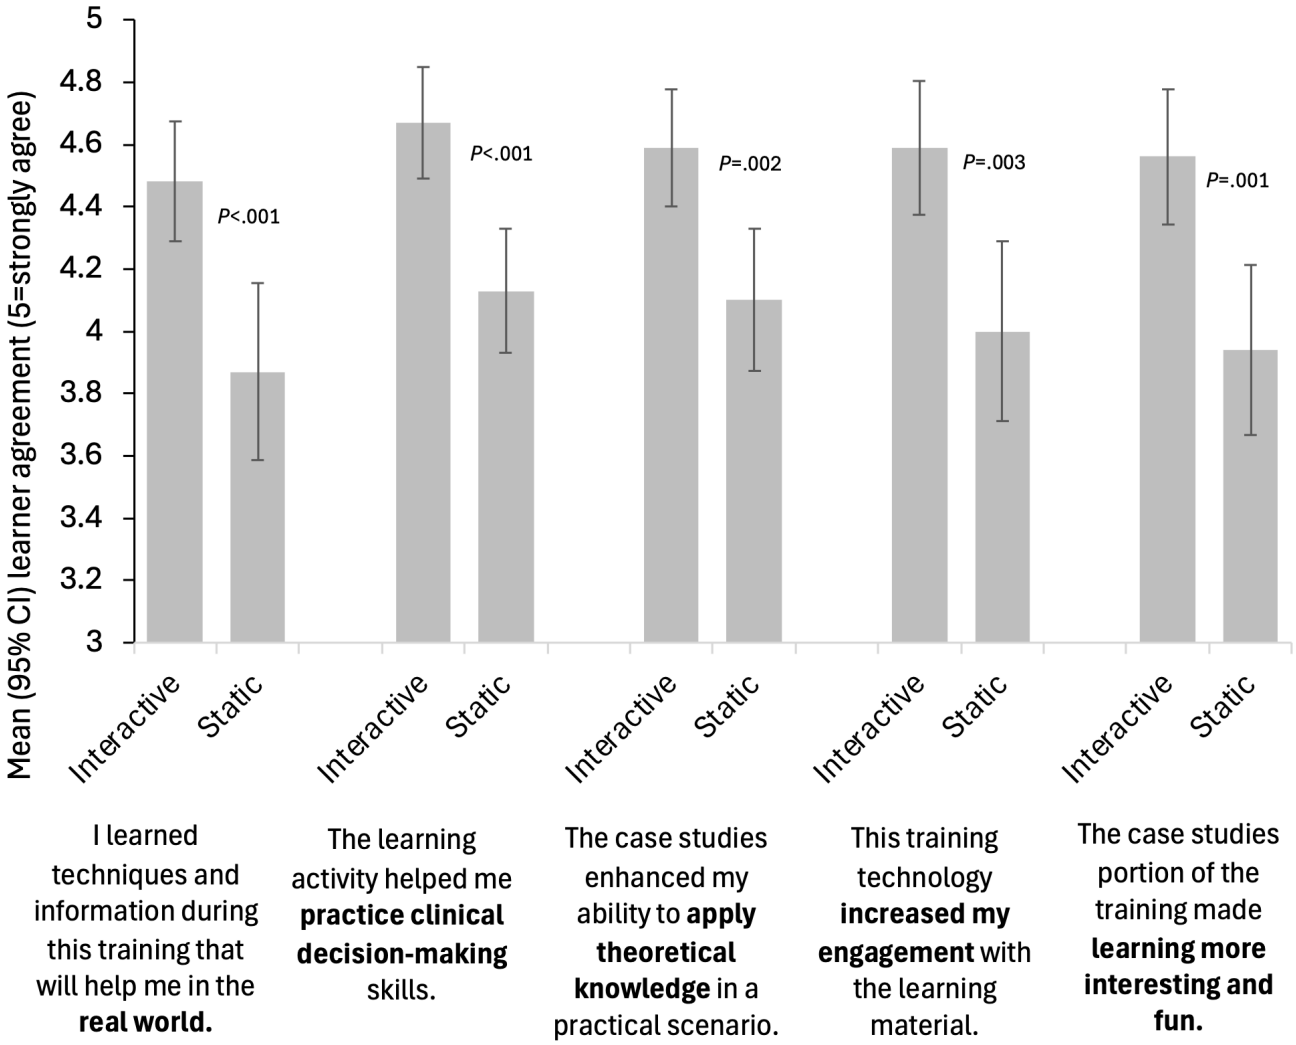
7%), non-Hispanic (n=50, 86%), and prefer-not-to-say (n=4, 7%). Degree programs were allied health professions (n=34, 59%), medicine (n=13, 22%), pharmacy (n=7, 12%), graduate studies (n=2, 3%), dental medicine (n=1, 2%), and nursing (n=1, 2%). Of the 74 enrolled participants, 38 (51%) were randomized to the written-case group and 36 (49%) to the interactive-case group; among the 58 completers, 31 (53%) were in the written-case group and 27 (47%) in the interactive-case group. Sample sizes, mean age, and mean pretest knowledge scores by category are shown in Table 1.

Knowledge Gains

Internal consistency of the 8-item knowledge test was modest (Cronbach α=0.56), as expected for a brief, custom instrument, and this value should be considered when interpreting the knowledge results. A 2×2 mixed ANOVA revealed a significant time (pretraining to posttraining)×group (written vs interactive) interaction ($F_{1,56}$=4.39; P=.04; partial η^2=0.07), indicating greater knowledge gains in the interactive condition; the posttest between-group difference was also significant (P=.03). Figure 3 shows the percent improvement from pretraining to posttraining by group.

Figure 3. Mixed ANOVA results showing changes in knowledge scores from pretraining to posttraining by group (interactive vs static).

Case Discussion Quiz Accuracy



Internal consistency of the case discussion measure across the 9 dichotomously scored items (3 discussion questions after each of 3 cases) was low (Cronbach α=0.31). This is expected and does not necessarily indicate measurement error: although the same prompts followed each case, the correct responses differed across cases, which represented distinct clinical scenarios. The items were not intended to function as parallel indicators of a single latent construct; rather, they sampled performance across heterogeneous cases. Accordingly, the case discussion score is interpreted as an aggregate performance measure across cases rather than as a homogeneous psychometric scale. Participants in the interactive condition demonstrated significantly higher accuracy (mean 0.79, SD 0.15) than those in the written condition (mean 0.64, SD 0.11; t_{56}=4.48; P<.001), corresponding to an approximately 25% relative advantage for the interactive format.

Learner Engagement

Internal consistency of the 17-item engagement questionnaire was high (Cronbach α=0.95). Agreement scores were significantly higher in the interactive group than in the written group on 13 of the 17 items (P<.05). Figure 4 shows group-level means (95% CI) on five key indicator items: (1) I learned techniques and information during this training that will help me in the real world; (2) the learning activity helped me practice clinical decision-making skills; (3) the case studies enhanced my ability to apply theoretical knowledge in a practical scenario; (4) this training technology increased my engagement with the learning material; and (5) the case-studies portion made learning more interesting and fun. Full item-level results are shown in Table 2. Because these were 17 uncorrected, item-level comparisons, the pattern is interpreted as consistently supportive of greater engagement in the interactive condition rather than as a set of independent confirmatory findings.

[a]Items used a 5-point Likert scale (1="strongly disagree" to 5="strongly agree").

[b]All comparisons were conducted using 2-tailed independent-sample *t* tests (interactive cases, n=27; written cases, n=31). Where Levene test indicated unequal variances, the Welch correction was applied, and the adjusted *df* are reported.

Discussion

Principal Findings

In this randomized controlled trial, students assigned to the interactive case condition demonstrated higher short-term knowledge gains, higher case discussion accuracy, and higher engagement than students assigned to the written case condition with identical content. These findings support the value of an interactive virtual patient format for case-based learning in health professions education. They are, however, preliminary and primarily hypothesis-generating, and, as detailed below, the design does not permit attribution of the observed benefits to AI specifically.

Interpretation: An Interactive-Format Effect, Not an Isolated AI Effect

The strongest interpretation supported by this design is that an interactive, AI-enabled virtual patient format outperformed a static written format delivering the same content. The trial cannot separate the contribution of AI from the contributions of conversational interactivity, learner agency, adaptive questioning, or additional time-on-task because these features are bundled within the interactive condition. We therefore frame

XSL•FO
RenderX

the results as support for interactive virtual patient learning rather than as evidence of a distinct, AI-specific advantage. At a minimum, integrating an LLM did not detract from the benefits of interactive learning; quantifying the incremental value of AI over non-AI interactive formats will require trials that include a non-AI interactive comparison arm.

Comparison With Prior Work

Our findings align with and extend prior research on simulation-based and active learning, adding randomized evidence that an interactive virtual patient platform can yield both measurable learning advantages and operational scalability [5,6,10-12]. The use of AI to deliver clinical cases has been examined in a range of recent studies [20], and some work suggests that simple LLM-generated cases may be less engaging than complex real-world cases [21]; our results, using facilitator-authored cases delivered through an interactive interface, are consistent with the broader active-learning literature [13-15] showing the benefits of interactivity over passive formats. Although this study addressed pain management, the instructional mechanism is not necessarily content-specific, and the observed benefits may extend to other domains that rely on clinical reasoning, communication, and applied decision-making. The extent to which these effects generalize across content areas, learner levels, and curricular structures remains an empirical question.

Clinical Reasoning, Data Access, and Demographic Context

Interactive virtual patients can train skills beyond communication; in the platform used here, learners could access a structured medical record and order facilitator-defined assessments (eg, laboratory results, medication and allergy lists, and prior treatments), so the encounters were designed to *unfold* components of case information (as opposed to openly presenting them as part of the vignette, as in the text-based case format) in addition to facilitating conversation alone. Nonetheless, this study did not separately measure information-gathering behavior, and future work should evaluate how access to and use of clinical data within the simulation relate to reasoning outcomes. Second, the realism of any virtual patient depends on the demographic and socioeconomic context authored into the case. The 3 cases here specified patient demographics and social context, but 3 US-based cases cannot represent the full range of geographic, socioeconomic, and cultural circumstances that shape pain management; readers should not generalize these specific encounters to all settings, and future case libraries should deliberately span diverse contexts and be evaluated for bias.

AI Reliability and the Need for Verifiable Content

LLMs can generate fluent but incorrect content, exhibit stereotyped patterns, and vary across runs [21]. In this study, the substantive clinical content and the scoring of reasoning were fixed and facilitator-authored, and guardrail prompts constrained the model to in-case information, which limits, but does not eliminate, the risk that a conversational reply could be inaccurate. We did not perform automated, turn-by-turn verification of model responses against the source record. Educational deployments of LLM-based virtual patients should therefore incorporate safeguards such as authoritative source content, explicit guardrails, human review, and, where feasible, explainable or verification-oriented architectures [22,23], and they should also monitor for inaccurate or biased output.

Limitations

Several limitations should be acknowledged. First, this was a completer-based analysis: 16 of 74 enrolled participants (22%) discontinued before the case study portion, and because reasons for attrition are unknown, unmeasured differences between completers and noncompleters could have biased the observed group differences and may limit conclusions about feasibility, acceptability, and generalizability. Second, time-on-task was not measured; students in the interactive condition may have spent more time with the material, and this duration effect cannot be disentangled from the modality itself. Third, voluntary participation may introduce self-selection bias toward learners more favorably disposed toward technology-assisted learning. Fourth, the assessment instruments were brief, with modest (knowledge test; Cronbach α=0.56) to low (aggregate discussion score; Cronbach α=0.31) internal consistency, limiting the granularity of measured learning. Fifth, the study was conducted at a single center with a modest sample (n=58) and was powered only to detect medium-to-large effects; small effects could have been missed. Sixth, only immediate postintervention outcomes were assessed; data on knowledge and skill retention at 6 or 12 months were not collected and are an important gap. Finally, the effects of AI cannot be separated from the broader benefits of interactivity, and 2 authors (JJB and DH) are founders of the company that commercializes the platform under study; although this conflict is disclosed and the substantive content and scoring were author-fixed, independent replication by investigators without a commercial interest is essential.

Future Directions

Future research should include a non-AI interactive comparison arm to isolate any incremental AI effect; measure time-on-task and in-simulation data-gathering behavior; assess retention at 6 and 12 months and transfer to authentic clinical performance; use validated, multifaceted assessments; and recruit larger, multi-institutional, and demographically diverse samples through curricular integration. Work on explainable and verifiable AI [22,23] may help ensure that conversational responses remain clinically accurate and interpretable as these tools scale.

Conclusions

This preliminary randomized controlled trial suggests that an interactive virtual patient format may be a portable, scalable, and feasible way to realize the benefits of interactive, case-based learning. Compared with static written cases of identical content, students in the interactive condition showed greater short-term knowledge gains, higher case discussion accuracy, and stronger engagement. These results are hypothesis-generating and reflect an interactive-format effect that cannot be attributed to AI specifically; they should be interpreted in light of completer-based analysis with unexplained attrition, voluntary participation, brief assessments, the absence of time-on-task and retention data, and the authors' commercial interest. Larger,

XSL•FO
RenderX

multi-institutional, longitudinal, and independently conducted trials—ideally including non-AI interactive comparison conditions—are needed to confirm durability and generalizability and to determine the unique contribution, if any, of AI to learning outcomes.

Abstract

Background: Midwifery education in Nigeria is undergoing a transformation in pedagogical approach. Existing traditional teaching materials are being supplemented by digital technology-enhanced learning resources; however, educators' limited pedagogical capacity may hinder their adoption. Thus, train-the-trainer (TTT) workshops were implemented to build capacity among midwifery educators to prepare them for the implementation of a digital learning platform across 20 institutions in Nigeria.

Objective: This study aimed to describe the development and qualitative evaluation of a TTT program to support the implementation of a technology-enhanced learning platform within preservice midwifery education in Nigeria. We aimed to evaluate participants' perceptions of the training and their preparedness to implement their learning.

Methods: The workshop was developed using the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) instructional design model. A 3-day TTT program was delivered in 2 cohorts in July 2025 to a purposive sample of 80 institution-nominated midwifery educators and information and communication technology officers from 20 pilot institutions. A qualitative descriptive study was conducted to explore participants' perceptions of the training and their readiness to implement and support the technology-enhanced learning platform within their institutions. Data were analyzed using qualitative content analysis.

Results: Pre-workshop responses demonstrated varying levels of prior exposure to and use of digital technologies, as well as differing expectations of the training. Four themes emerged from the post-workshop evaluation. Participants perceived improvements in their understanding of pedagogical and technology-enhanced learning approaches; reported greater readiness to support implementation and knowledge transfer within their institutions; highlighted infrastructure and technical support barriers to implementation; and emphasized the need for ongoing capacity building, monitoring, and support to promote long-term sustainability.

Conclusions: Rather than evaluating educational outcomes, this study provides early evidence of educator readiness, implementation considerations, and sustainability requirements for technology-enhanced learning in preservice midwifery education in low-resourced settings such as Nigeria. A multifaceted approach combining capacity building, ongoing support, technical requirements, and institutional commitment to continuous improvement is needed. Future phases of this implementation research will evaluate educational, implementation, and institutional outcomes associated with the digital learning platform.

Introduction

Nigeria has a maternal mortality rate of 993 per 100,000 live births, more than 3 times the global average of 211 per 100,000 live births [1]. The country continues to experience poor maternal and newborn health outcomes, partly attributable to deficiencies in the quality of midwifery education. Nigeria is unlikely to make substantial progress toward achieving the Sustainable Development Goals (SDGs) related to maternal and newborn health [2] without strengthening preservice midwifery education, particularly in northern states disproportionately affected by high maternal mortality, health workforce shortages, insecurity, and ongoing unrest associated with conflict and instability [3]. Digital learning approaches can support more flexible and scalable educational delivery, strengthen educators' capacity, and supplement existing preservice training with interactive, clinically relevant content [4-6]. Therefore, increased investment in midwifery education in Nigeria is necessary to ensure that international standards for quality education are met and to lower the extremely high maternal and newborn mortality rates [7,8].

Internationally, strengthening midwifery education is recognized as a critical strategy for reducing preventable maternal and newborn mortality and achieving the SDGs [9]. The International Confederation of Midwives (ICM) calls for midwifery education to meet international competency standards while remaining responsive to local population and health system needs [10]. Similarly, global initiatives such as the World Health Organization's Ending Preventable Maternal Mortality agenda and the Midwifery Accelerator Framework emphasize the importance of investing in a competent, well-supported midwifery workforce as a foundation for improving maternal and newborn outcomes [11,12]. High-quality midwifery education is therefore essential for equipping practitioners with the knowledge, clinical competence, and respectful care approaches required to deliver safe and effective maternity care across diverse settings [8].

Midwifery education in Nigeria is delivered primarily through schools of nursing and midwifery, colleges of health technology, and universities, and is regulated by the Nursing and Midwifery Council of Nigeria (NMCN). The Nigerian midwifery curriculum, recently revised, does not fully align with the ICM's Global Standards, which outline the minimum requirements for preparing competent midwives [13]. There are, however, significant challenges within preservice midwifery education in Nigeria. Midwifery training institutions face increasing pressure from workforce shortages, limited educational resources, and inconsistent access to clinical learning opportunities [8,14]. The expertise of midwifery educators in Nigeria is variable, with many tutors having strong clinical backgrounds but limited formal preparation in pedagogy, as well as limited access to contemporary teaching technologies, simulation resources, and ongoing educator development opportunities necessary to support competency-based and student-centered learning [7,14]. Thus, the delivery of education is predominantly teacher-centric, with heavy reliance on didactic instruction and rote learning [15]. Consequently, there is a growing need for innovative, student-centered educational approaches that support self-directed learning, critical thinking, clinical reasoning, and greater engagement with evidence-based midwifery practice.

Previous studies suggest that technology-enhanced learning can help address gaps in midwifery education by enriching teaching and learning and supporting more flexible, interactive, and student-centered educational approaches [6,16,17]. When integrated with traditional classroom teaching, digital technologies can accommodate diverse learning styles and promote greater learner engagement compared with predominantly didactic methods [16,18]. However, effective integration of digital technologies into midwifery curricula requires adequate educator preparation, technical support, and ongoing capacity strengthening to support implementation, adaptation, and sustainability [17,19]. As key drivers of digital transformation in education, midwifery educators require sufficient pedagogical and digital competence to effectively facilitate and support student learning in increasingly technology-enabled environments [20].

To support the effective integration and sustainability of technology-enhanced learning approaches in midwifery education, there is a need for structured capacity-building initiatives that strengthen the pedagogical and digital capabilities of educators and institutional support staff [19]. One approach increasingly used in health care education and workforce development is the train-the-trainer (TTT) model. The TTT method provides participants with the knowledge and expertise to become skilled trainers, enabling them to transfer their acquired knowledge and skills to others within their professional group. TTT models involve experts preparing a nucleus group of professionals to disseminate knowledge, skills, and evidence-based practices to their peers within their own organizations [21]. This approach supports scalable capacity strengthening and the development of local expertise, especially in limited-resource settings, promotes peer-supported learning, and may enhance the implementation of new practices within routine health care and educational settings [22]. Although TTT programs can facilitate the delivery of digital midwifery education at scale, robust and context-specific models are needed to ensure quality, sustainability, and local ownership.

Although technology-enhanced learning is increasingly being integrated into health professions education globally, the literature reports more on student learning outcomes than on the preparedness of educators and the institutional systems required to support sustainable implementation [15,23]. Limited evidence exists on how midwifery educators and institutional support staff in low- and middle-income countries experience and adapt to digital transformation initiatives, particularly within large-scale preservice education reforms [19].

Limited research has explored the design, implementation, and evaluation of training programs specifically developed to prepare midwifery educators for technology-enhanced learning approaches. Existing literature has largely focused on student experiences and digital learning outcomes, with comparatively less attention given to building the pedagogical and digital capabilities of educators responsible for integrating these approaches into preservice midwifery education. This gap is

XSL•FO
RenderX

particularly evident in low- and middle-income countries, where educators may have varying levels of exposure to digital technologies, instructional design, and online facilitation strategies.

This study provides novel evidence on a needs-informed TTT approach designed specifically to prepare midwifery educators to support technology-based learning in preservice midwifery education. Its contribution lies in addressing the limited evidence on how educators in resource-constrained settings can be equipped to integrate digital platforms and digital teaching approaches into existing midwifery programs. The findings advance knowledge by identifying practical strategies to strengthen midwifery educators' digital competencies and to support the effective and sustained implementation of technology-based learning within educational institutions. The study involved collecting baseline information on the perspectives of Nigerian midwifery educators and information and communication technology (ICT) officers regarding their participation in the initial TTT workshop.

Methods

Context of the Study

The NMCN digital learning platform was developed to deliver, manage, and monitor educational content for approximately 2000 preservice midwifery students across 20 pilot institutions in 11 states in Nigeria. In this pilot, 2 of the researchers, both international midwifery experts, codeveloped the digital modules. Each module features podcasts, simulations with first-person point-of-view videos, animations, and interactive technology-enhanced learning content focused on 3 maternal health conditions: postpartum hemorrhage and the E-MOTIVE bundle, multiple micronutrient supplementation for maternal anemia, and maternal sepsis. The 3 digital learning modules were developed to address major contributors to preventable maternal morbidity and mortality in Nigeria and other low-resource settings. They were designed to strengthen students' exposure to contemporary, evidence-informed maternal health content through interactive and technology-enhanced learning approaches that could supplement existing classroom and clinical education. Midwifery students across the pilot sites will access the platform over a 12-month implementation period, during which iterative refinement of the platform and educational content will be undertaken alongside ongoing evaluation of the technology-enhanced learning intervention's feasibility, acceptability, and usability.

TTT Program Development and Delivery

This study is part of a broader implementation research project introducing a digital learning platform into preservice midwifery education in Nigeria. The ADDIE (Analysis, Design, Development, Implementation, and Evaluation) instructional design model guided the development of the educational products and learning resources for the TTT program. This model is used as a structured framework for instructional design [24]. The model includes analysis of learner needs and educational objectives, design and development of instructional content and delivery approaches, implementation of the training, and evaluation to inform ongoing refinement and improvement. Although presented in phases, the ADDIE model is iterative and nonlinear in practice. As part of the evaluation phase, a qualitative descriptive study was conducted to explore the perspectives and initial experiences of midwifery educators and institutional ICT officers who participated in the TTT workshop.

The ADDIE Framework

Analysis

The analysis phase identified gaps in preservice midwifery education in Nigeria, including reliance on predominantly teacher-centered approaches that did not adequately support student learning outcomes or meet the objectives of the NMCN. A baseline assessment conducted between September and December 2024 identified shortages of midwifery educators, limitations in digital learning infrastructure and skills laboratories, and competency gaps among educators, preceptors, and final-year students in key maternal health areas, including postpartum hemorrhage management. These findings highlighted the need for strengthened educator capacity, improved learning resources, and innovative teaching approaches, including refresher training and technology-enhanced learning strategies.

Design

The design phase focused on planning the implementation of a technology-enhanced learning platform within existing preservice midwifery programs. Learning needs assessments identified limited digital literacy, insufficient experience with learner-centered teaching approaches, and varying levels of familiarity with digital technologies among educators. The TTT approach was selected to support scalable implementation and sustainability across pilot institutions. Educational content and module topics were predetermined within the broader project and developed collaboratively by Nigerian midwifery academics, project partners, and key stakeholders, including the NMCN, to ensure contextual relevance and alignment with curriculum standards. Two 3-day workshop sessions were designed for separate participant cohorts. Training objectives, session content, instructional activities, logistical requirements, and facilitation strategies were developed during this phase. The workshops incorporated practical activities, case studies, small-group discussions, and adult learning principles to promote active participation and peer learning. Nigerian midwifery educators led the delivery of the training, supported by the project team and technology partners, to enhance contextual appropriateness and communication.

Development

During the development phase, the original program developers created technology-enhanced learning resources and instructional materials for the TTT workshops, as they had the most in-depth understanding of the program. Due to contextual factors, including language and local communication styles, it was not feasible for the program developers to deliver the training directly. Therefore, it was planned that experienced Nigerian midwifery faculty with in-depth knowledge of the program would facilitate the training, with ongoing support and guidance from the original developers. A combination of theoretical and practical learning was used to equip trainers with the competencies needed to deliver high-quality cascade

XSL•FO
RenderX

training. Workshop materials were designed to model learner-centered and interactive teaching approaches while supporting participants' engagement with adult learning principles and instructional design concepts. A training handbook was developed to provide guidance on curriculum alignment, lesson planning, and integration of digital technologies into teaching and assessment. Additional workshop activities, including group-based exercises and interactive digital tools such as Mentimeter, were incorporated to support collaborative learning and participant engagement. Technology partners also developed platform-specific instructional resources covering platform architecture, navigation, login procedures, backend functionality, and user management. Effective adaptation strategies were introduced during the initial training and supported by planned supplementary training to reinforce learning and build confidence. Session schedules, durations, and training logistics were finalized during this phase (Multimedia Appendix 1).

Implementation

The TTT workshops were delivered in Abuja between July 14, 2025, and July 19, 2025, in 2 cohorts through intensive 3-day training sessions. The workshops aimed to prepare participants to support the implementation of the digital learning platform within their institutions and to cascade training to other midwifery educators. Training combined hands-on workshops facilitated by the technology partner with in-person and virtual sessions delivered by Nigerian educators and supported by the original program developers and the project team. Educational strategies included presentations, facilitated discussions, group work, demonstrations, and practical activities. Participants received an overview of the Moodle platform architecture and engaged in guided and independent navigation exercises exploring platform functionality, user roles, and educational content. Training explored challenging areas in greater depth, such as the integration of digital learning, and incorporated dedicated opportunities for questions and shared problem-solving. This initial training session focused on foundational digital literacy and platform engagement, with future training planned to support participants in independently creating and uploading digital learning resources and integrating the platform into existing teaching approaches.

Evaluation

This evaluation was not designed to formally assess feasibility, but rather to explore participants' perceptions and experiences of the TTT workshops to inform ongoing refinement of the training program and broader implementation processes. The evaluation used anonymous qualitative surveys administered before and after the training workshops. Pre-training questions explored participants' prior experiences, expectations, and perceptions of digital technologies, while post-training questions examined the perceived usefulness and acceptability of the training, as well as participants' perceived readiness to support implementation within their institutions. These insights were intended to inform educator readiness, engagement, and acceptability, while guiding future refinement, sustainability, and cascading of the intervention.

Research Design

A qualitative descriptive design [25] was used, as it enables researchers to remain close to the data while providing a comprehensive summary of participants' perspectives and experiences without aiming to generate theory or explore deeper, lived, or cultural meanings [26]. Qualitative description is particularly suited to examining who, what, and the context of events or experiences and is useful for exploring poorly understood phenomena through the accounts of participants [25]. This approach was selected because little is currently known about the perspectives and experiences of midwifery educators in Nigeria regarding the introduction of technology-enhanced learning resources and the expectations associated with adopting and disseminating new digital approaches within preservice midwifery education. Consequently, a qualitative descriptive methodology was considered appropriate for exploring participants' perceptions, experiences, and responses to this educational change introduced by the NMCN. Findings from the evaluation were used to identify areas requiring additional support, refinement, and future capacity-building activities.

Participants and Sampling

Participants were purposively selected by the NMCN from participating institutions based on their teaching responsibilities in courses linked to the digital learning modules, as course allocations are predetermined for the academic year. Institutional ICT officers were also included due to their roles in supporting digital infrastructure and platform implementation within the schools. Eligible participants included seasoned midwifery educators and ICT officers attending the TTT workshops who were not on leave, were involved in the relevant courses, and were willing to participate in the qualitative evaluation conducted before and after the training. A total of 80 participants attended 2 separate 3-day workshops. Although participants were nominated by their institutions to attend the training, participation in the qualitative evaluation component was voluntary, and participants were informed that their decision to participate or decline would not affect their involvement in the training program.

Data Collection

Qualitative data were collected through anonymous, written, open-ended responses before and after the workshops. This qualitative method can generate meaningful and rich insights, even when individual responses are brief, and minimizes participant discomfort [27]. This approach was selected based on participant preference, as some attendees were uncomfortable with audio-recorded interviews or group discussions, and it enabled participants to share their perspectives in their own words while minimizing burden within the intensive training schedule. Surveys were completed individually at the venue. Participants could remain at their allocated seats or choose another suitable location within the premises and were given approximately 30 minutes to record their responses. They wrote their responses by hand on the paper-based surveys and could request extra sheets as needed.

XSL•FO
RenderX

The pre-training survey comprised 5 questions that assessed participants' prior experience, expectations, and concerns about the training (Multimedia Appendix 2). The post-training survey included 9 open-ended questions that evaluated participant satisfaction, key learnings, intended actions, and areas requiring further training to inform future program planning (Multimedia Appendix 3).

Despite the anonymous, written format, social desirability bias may still have influenced responses, with participants potentially feeling inclined to provide favorable feedback due to their institutional nomination to attend the training and the broader implementation context.

Data Analysis

The research team followed the systematic steps of qualitative content analysis as described by Erlingsson and Brysiewicz [28], which include familiarization with the data, identifying meaning units, condensing those units, coding, categorizing, and formulating themes. Content analysis was chosen because it provides a systematic and transparent method for analyzing open-ended qualitative data across multiple participants. Data were analyzed manually without the use of qualitative software. Manual coding was selected to support collaborative analysis across the international research team and ensure accessibility for all researchers involved in the project. Two researchers independently reviewed and coded the responses before meeting to compare interpretations and discuss coding differences. Any discrepancies were resolved through discussion and consensus within the broader research team. Meaningful data segments relevant to the study objectives, including perceptions of the training, perceived learning gains, challenges, and anticipated application of skills, were identified and coded. The research team met regularly via Zoom to discuss coding decisions, resolve discrepancies through consensus, merge overlapping codes, and refine categories. Related codes were grouped into broader descriptive categories, which were subsequently developed into higher-level themes. Throughout the analytic process, categories and themes were repeatedly reviewed against the original written responses to ensure they accurately reflected participants' perspectives and experiences. Given the qualitative descriptive nature of the study and the use of brief written responses, the analysis aimed to achieve sufficient informational richness relevant to the study objectives rather than formal theoretical data saturation associated with interpretive methodologies.

Trustworthiness

To enhance the trustworthiness of the findings, several strategies were used throughout the analysis [29]. Credibility was enhanced through independent coding by members of the research team, followed by consensus discussions to resolve differences in interpretation and refine the coding framework. Dependability was supported through consistent data collection and analysis procedures, and by documenting coding decisions as the analysis progressed. To ensure confirmability, regular team meetings were held in which interpretations were critically examined and grounded in participants' responses rather than in individual assumptions. Transferability was facilitated by providing detailed information about the participants, training, and the study context. Researcher reflexivity was embedded throughout the analytic process and involved ongoing consideration of the researchers' roles, assumptions, and involvement in the program, as well as their potential influence on data collection, analysis, and interpretation.

Ethical Considerations

Ethical approval for this study was obtained from the Human Research Ethics Committee of Charles Darwin University, Australia (ethics number H25071), and the institutional Research Ethics Committee at the Liverpool School of Tropical Medicine (ethics number 24 - 074). The study was conducted in accordance with internationally accepted ethical principles for research involving human participants. All participants were provided with adequate information about the study objectives, procedures, potential risks, and benefits. Informed consent was obtained from all participants before data collection. Consent was sought both verbally and in writing, and participation was not compulsory. Confidentiality and anonymity were maintained throughout the study, and participation was entirely voluntary, with the right to withdraw at any stage without penalty. Prior to data collection, participants were informed verbally and in writing that completion of the evaluation activities was optional and would not affect their participation in the training or their professional roles. None of the participants objected to participating. Participants were also informed that they could decline to answer any question or withdraw at any time without consequence.

Results

In total, 80 participants took part in the study, comprising 60 female participants and 20 male participants. Most participants (n=58, 72.5%) were midwifery educators, alongside 21 ICT officers and 1 clinical instructor (Table 1).

[a]ICT: information and communication technology.

Pre-Training Responses

Pre-training responses revealed considerable variation in participants' prior exposure to digital tools, current technology use, and expectations for the training. Although some participants reported prior digital training, these experiences were often described as basic, outdated, or insufficient, whereas others relied mainly on self-directed learning and trial-and-error. This finding suggests limited access to structured and ongoing digital capacity development across participating institutions.

Participants' current use of digital tools was generally limited to basic applications, such as PowerPoint, WhatsApp, and online videos, with only a few having prior experience with platforms like Moodle. Despite these limitations, participants expressed strong interest in developing practical digital teaching skills, particularly in navigating learning management systems, creating digital content, integrating multimedia resources, improving online student engagement, and enhancing digital assessment practices. The findings indicate a strong demand for hands-on, practice-oriented training to strengthen educators' readiness for technology-enhanced teaching.

Post-Training Responses

Post-Training Perceptions and Experiences

The post-training responses highlighted 4 themes that articulated participants' perceptions and experiences of the TTT session—theme 1: developing pedagogical and digital teaching competencies; theme 2: self-perceived confidence and readiness to support implementation; theme 3: perceived barriers and logistical challenges; and theme 4: sustaining technology-enhanced learning.

Theme 1: Developing Pedagogical and Digital Teaching Competencies

Following the training workshop, participants described a greater understanding of both educational pedagogy and digital concepts. They described acquiring foundational knowledge and practical skills to effectively use digital tools and navigate the teaching platform. This highlights that the training was instrumental in helping educators align digital resources with the existing curriculum, thereby strengthening the relevance and integration of technology within learning activities. The structured and progressive nature of the training appeared to help participants connect pedagogy, curriculum outcomes, and technology-enhanced learning in more practical ways.

> *The training was progressive, with each part building upon the previous one. It was a step-by-step process: you must understand the learning objectives in the curriculum because they go hand in hand.* [Cohort 2, Respondent 23]

The lesson-planning component was particularly valued because it strengthened participants' understanding of learning outcomes, learner characteristics, and Bloom's taxonomy, while improving

XSL•FO
RenderX

their ability to design effective lessons and organize courses sequentially.

> *I have also learned how to make a lesson plan, which will bring a breakthrough in my teaching activities and help me achieve the outcomes I want for my students. It [Lesson plan] also helps us, as educators, to create a sequential model that makes our work flexible and enhances student learning.* [Cohort 1, Respondent 1]

Participants further noted that the knowledge gained from lesson planning and course organization would improve student learning outcomes.

> *This will improve learning outcomes for my students..., understanding how a course is designed and organized online.* [Cohort 2, Respondent 22]

Participants described gaining a broader understanding of educational principles, including different types of learners, teaching approaches, learning activities, and Bloom's taxonomy. They perceived this knowledge as enhancing their understanding of how teaching and learning can be effectively supported through the learning management system.

> *I also gained knowledge on the different types of students, lecturers, and educators, the various kinds of learning activities, and the six types of Bloom's taxonomy. All these have helped me understand teaching and learning through the LMS.* [Cohort 1, Respondent 4]

Participants reported gaining practical skills in using the learning management system, including creating assessments, delivering lectures, uploading educational content, developing multimedia learning materials, and monitoring student engagement and participation.

> *I have gained a great deal from learning how to log in to the computer and navigate it. I also learned how to use the computer in teaching and incorporating videos. In addition, I gained knowledge of the learning management system, how to navigate the portal, and an overview of creating content.* [Cohort 1, Respondent 15]

Participants described the content and resources as appropriate, useful, and accessible, supporting both teaching and student engagement. Participants appreciated the use of Nigerian voiceovers and actors, which increased the realism and contextual relevance of the learning experience.

> *The parts of the training I found most useful and impactful were those that made teaching and learning more realistic, efficient, and effective by utilizing podcasts, videos, pictures, animations, drag-and-drop features, and scenarios. This is because these will make teaching and learning easier and more interesting for both the trainer and the learner.* [Cohort 2, Respondent 23]

These findings suggest that participants required support not only in the technical use of digital platforms but also in the pedagogical foundations necessary to effectively integrate technology-enhanced learning into existing teaching practices. The overlap between educational and digital competencies highlights that successful digital transformation requires more than technological infrastructure; it also requires educator preparedness and confidence in applying learner-centered teaching approaches.

Theme 2: Self-Perceived Confidence and Readiness to Support Implementation

Following the training, participants described greater perceived confidence and readiness to support the implementation of technology-enhanced learning within their institutions. Participants attributed this readiness to the practical, hands-on nature of the training, which enabled them to actively engage with the platform, explore its functionality, and apply newly acquired knowledge in a supportive learning environment. There were 2 subthemes: valuing practical, hands-on learning and commitment to training others.

Subtheme 1: Valuing Practical, Hands-On Learning

Participants consistently highlighted the workshop's practical, interactive design as a key facilitator of learning. Opportunities to navigate the platform, engage with activities, and apply concepts in real time were perceived as particularly valuable for building familiarity with technology-enhanced learning approaches.

> *I found the training to be very engaging and participatory, with everyone actively involved typing and clicking on their computers, logging in and out.* [Cohort 2, Respondent 3, post-training]

Another participant added:

> *The practical aspect of the training was the most useful because it made learning easier for me. It was better to do it myself, and I felt more confident by the second day. It has motivated me to use a laptop to teach. Henceforth, I will continue to try my hand at creating blended lectures.* [Cohort 2, Respondent 4, post-training]

The workbook and workshops enhanced participants' confidence and motivation, equipping educators with resources to support students' use of digital tools during implementation.

> *I was previously hesitant about using technology in training and teaching, but this program gave me the confidence to utilize digital tools effectively.* [Cohort 2, Respondent 5, post-training]

However, some participants felt that additional training sessions would help consolidate learning and build confidence over time. They noted that the breadth of content introduced during the workshop required additional time and practice to fully understand and apply it. They collectively emphasized that ongoing training and support would be essential to sustain their engagement.

> *Organise training 2 - 3 times per year...especially creating PowerPoints.* [Cohort 1, Respondent 20, post-training]

XSL•FO
RenderX

> *I suggest that more days should be allocated to this type of training next time, enabling us to fully grasp everything.* [Cohort 2, Respondent 20, post-training]

These findings indicate the importance of embedding continuous professional development, technical support, and implementation coaching within technology-enhanced learning initiatives to facilitate long-term adoption and integration into teaching practice.

Subtheme 2: Commitment to Training Others

Participants expressed a strong willingness to disseminate the knowledge they acquired through this process through step-down training, viewing this as essential to ensuring the platform's success and sustainability. Many described intentions to organize training sessions for colleagues, support the implementation of the digital learning platform, and begin developing or uploading their own educational content.

> *I plan to train other educators [on this training], involve students, and ensure that they can access the platform. I will be very excited to start uploading my own modules to improve the learning and teaching process.* [Cohort 1, Respondent 5]

Participants also outlined strategies for preparing to cascade the training, including reviewing workshop materials, revisiting the training workbook and notes, and developing action plans tailored to their institutional contexts.

> *This is how I plan to apply what I learned in my own teaching practice: first, to become very familiar with the process of logging in and using the platform so that I can effectively transfer the knowledge and skills to my colleagues and students. I will then ensure that my students are referred to the modules. I will also create content to further support their learning.* [Cohort 2, Respondent 3]

Another participant explained,

> *Before I train my colleagues, I will review my notes and develop an action plan.* [Cohort 2, Respondent 18]

These findings suggest that participants viewed themselves not only as recipients of training but also as potential change agents within their institutions. Their willingness to train colleagues, develop educational content, and plan implementation activities reflects their perceived readiness to support the broader adoption of technology-enhanced learning.

Theme 3: Perceived Barriers and Logistical Challenges

Participants identified infrastructure and ongoing support as critical determinants of successful implementation. Common concerns included unreliable internet connectivity, unstable power supply, limited sensitization, and access to timely technical support. The provision of free internet access was frequently proposed, underscoring the need to address systemic and infrastructural barriers to the sustainable integration of technology-enhanced learning.

> *All necessary facilities, such as internet access and power supply, should be ensured, as they are very important.* [Cohort 2, Respondent 17]

Participants identified technical support and access to adequate resources as essential for sustaining digital learning and the effective implementation of the program. Participants also emphasized that resource availability, including access to laptops and embedded training materials, could enhance the consistency and ease of training delivery.

> *Yes, my suggestion is that laptops should be provided to master trainers, with all the topics embedded into the laptop.* [Cohort 2, Respondent 20]

Participants highlighted the importance of collaboration between educators and ICT officers, emphasizing the need for shared training opportunities and equal access to the platform. This finding suggests that successful implementation of technology-enhanced learning requires a team-based approach, with clearly defined roles and shared responsibility to support sustainability and reduce reliance on individual staff members.

> *Both midwife educators and Information Technology officers should be trained at the same level so that the ICT officers will not be overwhelmed with loads of responsibilities.* [Cohort 1, Respondent 5]

Theme 4: Sustaining Technology-Enhanced Learning

Participants highlighted the importance of continuity in future training activities, expressing a preference for the same facilitators who introduced the platform to lead subsequent training sessions, thereby providing continuity in learning, reinforcing key concepts, and supporting a deeper understanding of both the platform and its educational applications.

> *There is a need for more training on content creation and uploads. The NMCN should organise such training two to three times per year.* [Cohort 2, Respondent 29]

> *Future training should include the same educators who introduced the platform to ensure continuity and a deeper understanding.* [Cohort 1, Respondent 8]

Participants identified several strategies to support successful implementation and ongoing engagement with the platform. These included regular system maintenance and updates to enhance usability, development of user-friendly navigation tutorials such as YouTube videos, routine check-ins to monitor progress and address challenges, and the establishment of clear expectations for appropriate behavior in both classroom and online learning environments.

> *a) Regular maintenance and updates that can enhance user experience, b) tutorials on navigating the platform, which can be in the form of YouTube videos, c) implementation of regular check-in strategies, and d) clear guidelines for acceptable behaviour within the classroom and online.* [Cohort 1, Respondent 22]

Participants generally valued the training but suggested that online sessions could be made more engaging through greater visual interaction with facilitators. This finding highlights the importance of facilitator presence in online learning

XSL•FO
RenderX

environments and reflects the practical challenges of delivering technology-enhanced learning in settings where limited internet bandwidth may restrict the use of video and other interactive features.

> *I suggest that the online lectures be made more engaging and less boring, perhaps by allowing us to see the presenters or facilitators.* [Cohort 2, Respondent 26]

Together, these findings suggest that sustained implementation requires ongoing capacity strengthening, resource investment, and responsive support systems, rather than one-off training interventions.

Discussion

Principal Findings

Participants in this study perceived that the TTT program enhanced their understanding of technology-enhanced learning and increased their confidence in supporting its implementation in preservice midwifery education. They also expressed a willingness to champion digital learning in their institutions. However, participants consistently identified inadequate digital infrastructure, limited technical support, and the need for ongoing training as important considerations for sustaining its implementation. The study's insights contribute to a growing evidence base by identifying contextual factors that educators perceive as important for integrating digital learning into preservice midwifery education in resource-constrained settings.

The findings suggest that the success of TTT programs for technology-enhanced learning extends beyond knowledge acquisition and requires attention to implementation readiness, contextual barriers, and strategies that support long-term sustainability, consistent with evidence synthesized in a recent scoping review [19]. Such evidence is scarce in midwifery education, particularly in the context of nationwide initiatives in countries with high maternal mortality, where strengthening the midwifery workforce is critical to improving maternal and newborn outcomes [9].

Prior studies have demonstrated that TTT initiatives can improve knowledge, confidence, and teaching competencies [21,30,31]. Although this study did not measure these outcomes quantitatively, participants reported increased confidence, readiness to train others, and motivation to apply newly acquired skills, all of which are required for successful implementation and sustainability [30,32]. In contexts where educator shortages and limited resources constrain professional development opportunities, such gains may be critical for supporting the successful implementation and scale-up of technology-enhanced learning. These qualitative findings extend the existing evidence by providing a deeper understanding of the processes through which TTT programs build implementation capacity and foster sustainable educational change.

Gaps in pedagogical and digital competencies can directly affect the quality, implementation, and sustainability of technology-enhanced learning, as well as training outcomes at different levels. Although participants were enthusiastic about the TTT program and eager to apply their new knowledge, many lacked a foundational understanding of teaching and learning principles, reflecting a reliance on traditional didactic approaches. These findings should be understood within the broader Nigerian educational environment, where educator shortages, limited professional development opportunities, and inadequate digital skills training are well-documented [7,15]. Within midwifery education, large student cohorts and high educator-to-student ratios further reinforce didactic teaching practices [15]. In this context, the program addressed an important capacity gap by strengthening educators' pedagogical and digital competencies and equipping them to support teaching and learning despite significant workforce and resource constraints.

In this study, resistance to educational innovation was not the issue. Participants demonstrated openness to change and a willingness to experiment with new teaching approaches. While participants were enthusiastic about technology-enhanced learning, they frequently highlighted unreliable internet connectivity and electricity supply as key barriers to implementation. These infrastructure challenges were viewed as important considerations for successful implementation, as reported in other settings [6,16,33,34], and are also consistent with broader reports describing digital infrastructure limitations across Nigeria [35,36]. While planned national investments in fiber-optic infrastructure may improve future connectivity, these findings suggest that digital education initiatives must be accompanied by investments in reliable internet connectivity, digital infrastructure, devices, and ongoing technical support that enable educators and students to fully engage with these resources to achieve their intended impact [34].

Sustaining digital learning initiatives requires supportive policy, leadership commitment, and ongoing training [34]. In low- and middle-income countries, where resources are constrained and priorities shift, understanding sustainability is critical [37]. Given Nigeria's size and security challenges, technology-enhanced learning strategies may offer a viable and scalable solution. Notably, there is a strong political commitment to advancing midwifery in Nigeria, as reflected in the Nigeria Strategic Directions for Nursing and Midwifery (NSDNM) 2025 to 2030, which acknowledges ongoing gaps in training, deployment, and retention of skilled midwives [38]. Situating participant-identified barriers within this national reform agenda highlights that, while targeted training to build educator capacity is essential, sustainable improvement will require continued investment in educational infrastructure, workforce development, and supportive policy frameworks.

The findings have several practical implications. First, digital capacity-building programs should incorporate both technological skills and foundational pedagogical training to support meaningful educational transformation. Second, implementation strategies should include ongoing mentorship, technical support, and opportunities for peer learning to reinforce skills gained during training [34]. This also includes diffusing expertise within the system through a strong community of practice, which was set up via WhatsApp group chats in this case. Third, policymakers and educational leaders should recognize that investments in educator capacity alone are unlikely to achieve sustainable change without concurrent

XSL•FO
RenderX

improvements in digital infrastructure, internet access, and institutional support systems [16].

Overall, the findings suggest that the TTT approach is a feasible and practical strategy for implementing technology-enhanced learning at scale. Future studies should examine the longer-term impact of the TTT model on behavioral outcomes, including educator practice, institutional adoption of technology-enhanced learning, and student learning outcomes. Evaluation of the planned training cascade will be particularly important in determining whether knowledge and skills are successfully transferred to additional educators and sustained over time. Further studies should also explore factors that influence implementation across different institutional and geographical contexts and identify strategies that support long-term sustainability of digital education initiatives in resource-constrained settings.

Limitations

This study has several limitations. First, a quantitative assessment of participants' pre-training and post-training knowledge and skills was not conducted, as the training was intentionally designed to foster a supportive, nonthreatening learning environment. Second, although a paper-based open-ended survey was deemed appropriate, it may have limited opportunities for deeper exploration of individual experiences and perspectives. Third, participants were nominated by their institutions to attend the training, which may have influenced perceptions of voluntariness, despite the evaluation being optional and anonymous. As the findings were based on self-reported written feedback collected within a funded implementation project, socially desirable responses cannot be excluded. Moreover, we did not objectively assess knowledge, skills, competence, or the extent of change attributable to the program. Therefore, the findings reflect perceived readiness, usefulness, and acceptability rather than measurable improvements in teaching practice or digital competence. In addition, the short duration of the training may have limited participants' confidence to cascade the training, and the absence of a structured buddying approach may have reduced opportunities for peer support and ongoing capacity building. As the broader implementation project is ongoing, future phases of the study will evaluate longer-term educational, institutional, and implementation outcomes associated with the technology-enhanced learning platform.

Conclusions

This study evaluated participants' perceptions of a needs-informed TTT program and their preparedness to implement a technology-enhanced learning platform in preservice midwifery education in Nigeria. It provides novel evidence in an underresearched area by showing how targeted educator training can strengthen digital competencies and support the implementation and sustained use of technology-based learning. Rather than evaluating educational outcomes or changes in practice, this study provides early evidence of educators' readiness to adopt student-centered innovative learning resources. Participants are motivated to share their learning and are enthusiastic about adopting the new resources on a digital learning platform. Nevertheless, our findings suggest that national implementation may require a structured strategy to equip educators with pedagogical principles to advance the widespread application across Nigeria. The findings also indicate that expanding technology-enhanced learning in preservice midwifery education in Nigeria is likely to require sustained institutional and government commitment to strengthening the infrastructure required to support digital learning platforms.

Acknowledgments

No generative AI tools were used in the preparation of this manuscript.

Funding

Funding for this study is provided by the Gates Foundation. The funder has no role in the study design, data collection, analysis, interpretation, or report writing.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to the ongoing nature of the implementation and the absence of participant consent for data sharing. All data relevant to the study's findings are included in the manuscript and the supplementary materials.

Authors' Contributions

IG conceptualized the study, mapped out the study design, supervised data collection and analysis, and spearheaded the drafting and review of the manuscript. NS contributed to the development of the instrument, recruitment of participants, and coordination of data collection and analysis. OT took part in data analysis, writing the original draft, the review and editing of the manuscript, and organized logistics needed during the study. MG contributed to the conceptualization and design of the study, drafting, review, and editing of the manuscript. HMA and AML contributed to the development of training resources, ensured contextual adaptation, and reviewed and edited the manuscript. Each author has read the completed work, given their approval for submission, and committed to taking personal responsibility for their contributions and for addressing any unanswered concerns.

Conflicts of Interest

Although this study formed part of a funded implementation project, the authors had limited involvement in the direct delivery of the train-the-trainer workshops. The workshops were primarily facilitated by Nigerian midwifery educators and technology partners. The authors did not hold supervisory, consultancy, or institutional authority roles over the participants.

Abstract

Background: The rapid progress in digital transformation and the increasing reliance on AI in health care have created an urgent need for validated assessments of digital and AI literacy among nursing students. However, there is a substantial gap in culturally adapted assessment tools for Arabic-speaking populations.

Objective: This study aimed to translate, culturally adapt, and conduct a preliminary psychometric evaluation of the Arabic version of the Nursing Digital and AI Literacy Assessment (NURS-DIAL).

Methods: This cross-sectional study evaluated the Arabic-translated and culturally adapted version of the NURS-DIAL. The psychometric evaluation included content validity, confirmatory factor analysis (CFA) using diagonally weighted least squares estimation, internal consistency reliability, construct validity, and known-groups validity. Given the complexity of the 52-item, 5-factor NURS-DIAL model and the limited sample size, the CFA findings should be interpreted as preliminary.

Results: Content validity was strong, with item-level content validity indices ranging from 0.83 to 1.00 and a scale-level content validity index average of 0.94. CFA provided preliminary support for a 52-item, 5-factor model after removing 4 items. Model fit indices were as follows: comparative fit index was 0.930, Tucker-Lewis index was 0.926, root mean square error of approximation was 0.055, standardized root mean square residual was 0.103, and goodness-of-fit index was 0.947. The internal consistency estimates ranged from 0.856 to 0.919. Selected known-group comparisons also provided preliminary validity evidence.

Conclusions: The NURS-DIAL demonstrated preliminary evidence of content validity, structural validity, internal consistency reliability, and construct validity among nursing students at 1 university in Saudi Arabia. Because of the limited sample size and single-institution setting, the tool should currently be used for exploratory research and formative assessment in similar settings. Larger multi-institutional studies are needed to confirm its factor structure and broader applicability.

KEYWORDS

digital literacy; mHealth literacy; artificial intelligence literacy; nursing students; digital well-being

Introduction

The rise of digitalization in health care and nursing education has created an increasing demand to evaluate nursing students' competence in using digital and AI technologies. Contemporary digital competency models in higher education emphasize 5 key domains: information literacy, digital well-being, digital research, content creation, and online identity management as essential for safe and effective technology use in learning and practice [1]. Recent studies have identified gaps in nursing students' self-perceived competence in information literacy, digital research, and digital innovation, while also highlighting the importance of digital health literacy, digital skills, and positive attitudes toward AI [2,3]. However, studies in the Gulf and wider Arab region have documented gaps among nursing and health professions students in information handling, critical appraisal, and digital self-management [4-6]. Moreover, a recent study of e-learning adoption in Gulf Cooperation Council (GCC) higher education institutions showed that students' use of e-learning systems was influenced by their perceptions of system usability and accessibility. These perceptions may affect students' ability to engage effectively with online learning environments [7].

The role of AI in nursing practice has grown rapidly in recent years. Nurses now use AI in clinical decision-support systems, diagnostic imaging, predictive analytics, documentation, patient

XSL•FO
RenderX

monitoring, and robotic technology. As AI becomes more integrated into patient care, nurses need to understand how to use it safely. This includes foundational knowledge of basic AI principles, the ability to use AI-supported tools appropriately, and the use of clinical judgment when considering AI-generated recommendations [8,9]. Therefore, nursing students should receive exposure to and training in AI, including their roles and responsibilities, before entering clinical practice [10,11].

In Saudi Arabia, nursing students displayed a wide range of perceptions and readiness for AI [12]. Some students expressed a lack of knowledge of and uncertainty about the concept of AI, though a majority were positively inclined to the technology [12]. Students with higher AI literacy expressed a greater sense of empowerment and a reduction in their fears about the technology [13]. Systematic reviews of the nursing literature on AI indicated that the integration of AI education programs in nursing programs can reduce nursing students' fears and improve their understanding of the technology [14]. A review of the literature on the concept of AI in the Middle East and North Africa indicated that a majority of the studies conducted and published on the topic originated from that region, but the majority of the studies did not use instruments developed within those countries to measure students' attitudes and readiness to use the technology [9].

There is a significant amount of nursing literature that discusses how Middle Eastern and North African countries feel about AI in nursing education. Some of the areas that have been studied within this region include nurses' attitudes toward AI, their literacy regarding the technology, their readiness for the technology, and their intentions to adopt AI into nursing education [9]. Despite the wealth of studies conducted within this region, there is limited reporting in the literature of how these studies were performed. In many of the Arabic language nursing education texts, the scales and questions used in the studies were developed in non-Arabic speaking countries, and there has been limited reporting of how these scales have been formally translated, culturally adapted, and psychometrically evaluated for use within the Middle Eastern and North African countries. There is a need not only to describe nursing students' attitudes and readiness for AI but, more importantly, to establish culturally appropriate measures for assessing digital and AI-related skills in Arabic-speaking educational environments. This study addressed this need by conducting an Arabic adaptation and preliminary psychometric analysis of the Nursing Digital and AI Literacy Assessment (NURS-DIAL).

The NURS-DIAL was developed to assess 5 related domains among nursing students: information literacy, mobile health (mHealth) literacy, AI literacy, digital well-being, and perceived AI education topics. The present study aimed to translate, culturally adapt, and conduct a preliminary psychometric evaluation of the Arabic NURS-DIAL among nursing students in Saudi Arabia. The study examined content validity, internal consistency, structural validity using confirmatory factor analysis (CFA), intersubscale associations, and selected known-group comparisons. Translation and cultural adaptation were undertaken using the stages recommended by Beaton et al [15], including forward translation, synthesis, back-translation, expert-committee review, and pretesting with members of the target population.

Methods

Study Design

This methodological cross-sectional study aimed to translate and conduct a preliminary psychometric evaluation of the Arabic version of the NURS-DIAL questionnaire among nursing students.

Population/Setting/Sampling

Convenience sampling was used to collect data from enrolled nursing students. Eligible students were invited to complete an online survey via institutional announcements and online learning platforms. The sample included undergraduate and postgraduate nursing students of all years of study and specializations in the field. The inclusion criteria were age 18 years or older, ability to read Arabic written language, and electronic informed consent. Exclusion criteria were students enrolled in nonnursing programs and students who participated in the pilot phase of NURS-DIAL. The final sample included 196 nursing students.

Sample-Size Consideration

The final sample included 196 nursing students. Although this sample exceeded the absolute minimum of 100 participants, it was still small in relation to the complexity of the model. The final instrument contained 52 items across 5 dimensions. Therefore, the participant-to-item ratio was approximately 3.8:1. This ratio is less than the commonly recommended ratios of 5 to 10 participants per item and more conservative recommendations for complex CFA models. In other words, the sample size was adequate for the initial psychometric evaluation but not for the final confirmation of the factor structure. The CFA findings should be viewed as preliminary and verified in further studies using larger independent samples. Additionally, future studies should use a priori model-based sample size estimation or Monte Carlo power analysis that considers the number of factors and indicators, expected factor loadings, residual variances, correlations between factors, ordinal response categories, estimator type, and anticipated missing values.

Development and Governance of the NURS-DIAL

The NURS-DIAL was created through a multinational research collaboration (AI4Health consortium) to evaluate nursing students' knowledge of digital and AI literacy in 5 areas. Four previously used tools were integrated into the NURS-DIAL: the information literacy and digital well-being subscales of Martzoukou et al [2], Discipline-Based Digital Competence Survey Battery, mHealth Literacy Scale of Kim et al [16], Artificial Intelligence Literacy Scale of Wang et al [17], and Education Topics Needs Survey of Civaner et al [18] on AI.

The initiative involves nursing faculties and departments in several countries: UMIT TIROL in Austria, the University of Maribor Faculty of Health Sciences in Slovenia, and the University of Hail in Saudi Arabia, where the current sample was recruited. All participating institutions follow a common

XSL•FO
RenderX

research protocol, obtain approval from their local ethics committees, and translate and culturally adapt the questionnaire for their own settings.

The consortium coordinating team manages the governance of the instrument, including curation of the item pool and cross-site coordination, while the project coordinators manage requests to use the instrument through the NURS-DIAL project website. Researchers and collaborating institutions can use the questionnaire at no cost. In the present study, the questionnaire was administered locally using Qualtrics and Google Forms. Parallel validation work is underway in additional cohorts, and preliminary findings have been reported in an Austrian cohort. To our knowledge, this study is the first to present an Arabic-language adaptation and preliminary psychometric evaluation of the NURS-DIAL.

The NURS-DIAL research team added 4 items to the AI Literacy subscale to better reflect AI literacy in the context of nursing and health care, as the original instrument was developed for general users, expanding the original 12-item scale [17] that measured AI literacy. Also, the AI Education Topics subscale was expanded from 15 to 20 items to include additional AI-related curricular priorities determined to be relevant to nursing education.

The Information Literacy subscale consists of 8 items, using a 5-point rating scale from novice to expert. The mHealth Literacy subscale consists of 6 items, using a 5-point rating scale from strongly disagree to strongly agree. The AI Literacy subscale consists of 16 items, using a 7-point rating scale from strongly disagree to strongly agree. The Digital Well-being subscale consists of 6 items, using a 5-point rating scale from novice to expert. The AI Education Topics subscale includes 20 items on a 5-point scale from include to no need describing the perceived priorities for AI content in the nursing curricula by students. Four items (AIL_c, AIL_g, DW_e, and AIE_t) were deleted after CFA, resulting in a final Arabic NURS-DIAL of 52 items.

Translation, Cultural Adaptation, Content Validity, and Pretesting

The NURS-DIAL was translated and culturally adapted into Arabic using the 5-stage framework described by Beaton et al [15] for cross-cultural adaptation of self-report measures. Permission to translate, adapt, and publish the questionnaire was obtained from the AI4Health consortium, and copyright requirements were met.

In stage 1, 2 bilingual translators independently translated the original English NURS-DIAL into Arabic. Both translators were native Arabic speakers, fluent in English, and had backgrounds in nursing or health sciences. In stage 2, the interdisciplinary research team reviewed and reconciled the 2 translations. The review focused on terms related to digital technology, AI, and reverse-worded items to ensure clarity and cultural relevance in the Saudi Arabic version.

In stage 3, the reconciled Arabic version was independently back translated into English by 2 bilingual translators whose first language was English, who were fluent in Arabic, and who were unfamiliar with the original questionnaire. In stage 4, a multidisciplinary expert committee reviewed the forward translations, reconciled Arabic version, and back-translations. The committee assessed semantic, idiomatic, experiential, and conceptual equivalence and produced a prefinal Arabic version of the NURS-DIAL.

Six experts reviewed the prefinal 56-item Arabic NURS-DIAL for content validity. The panel included 3 nursing education academics with 8, 12, and 15 years of experience, a health informatics expert with 10 years of experience, a linguist with 7 years of experience, and a psychometrician with 11 years of experience. All held doctoral degrees and had experience in instrument development. Experts rated each item for relevance, clarity, and cultural appropriateness on a scale from 1 (not relevant) to 4 (highly relevant). The item-level content validity index (I-CVI) values for all items were at least 0.83, and the scale-level content validity index average was 0.94. Based on the expert review, minor wording changes were made to 4 items to improve clarity and cultural appropriateness for use in Saudi Arabia.

In stage 5, the prefinal Arabic NURS-DIAL was tested with 35 nursing students who met the same eligibility criteria as the main study sample. After completing the questionnaire, students commented on the clarity of the items, wording, response options, time needed to complete the questionnaire, and cultural relevance. It took approximately 15 to 20 minutes to complete. Students did not report any concerns about cultural appropriateness, and no items were added. The research team reviewed the feedback before the main psychometric evaluation. The Arabic items, English backtranslations, response options, scoring directions, and item-retention status are provided in Table S4 in Multimedia Appendix 1.

Data Collection Procedure

Participants completed a self-administered online survey using Qualtrics and Google Forms. The survey could be accessed at participants' convenience using a smartphone, tablet, or computer. The survey link was sent out to nursing students via email, learning management system (LMS), and faculty posts for all program levels and years of study.

All invitation communications to standardize survey administration provided information on the study purpose, eligibility criteria, voluntary participation, and anticipated completion time and directed students to 1 online interface. The first page of the survey contained an information sheet and an electronic consent form, followed by items presented in a fixed sequence. The majority of closed-ended items were required; skip patterns were used only when conceptually justified; and the survey was designed for mobile accessibility to minimize missing data.

Statistical Analysis

Statistical analysis of the psychometric properties of the Arabic version of the NURS-DIAL was carried out on the main validation dataset. After screening the data, special codes were treated as missing values, and some items were reverse scored. Missingness was patterned, increasing monotonically with item position consistent with survey dropout (Spearman ρ=0.995; Tables S1 and S2 in Multimedia Appendix 1); the primary CFA used weighted least squares mean and variance (WLSMV) with

XSL•FO
RenderX

pairwise-present information, and the findings were robust to complete-case and multiple-imputation sensitivity analyses (Table S3 in Multimedia Appendix 1). Structural validity was evaluated with CFA using an appropriate estimator for ordinal data and standard fit indices. Internal consistency was evaluated by Cronbach α (≥0.70 was considered acceptable). Construct validity was assessed by intersubscale correlations for convergent and discriminant validity, while known-group validity was assessed by 2-tailed *t* tests and 1-way ANOVA on subscale scores.

Sex Reporting

In this study, sex was self-reported by participants in the online survey (male/female) and is used in the known-group validity analyses. Biological sex as recorded in official records was not assessed.

Ethical Considerations

Prior to beginning data collection, ethical approval was obtained from University of Hail's Institutional Review Board (case number H-2025 - 784). As part of obtaining informed consent, each participant was required to complete an electronic form that included a brief description of the study's purpose and procedures, potential risks/benefits of participating, as well as a statement indicating that participation was optional and that the student could withdraw or refuse to participate at any point during the completion of the survey and would incur no negative consequences. The survey was completed anonymously and did not include any identifying information.

Results

Table 1 summarizes the demographic and educational characteristics of the participants. Age data were available for 193 participants, with a mean age of 22.5 (SD 5.9, range 18 - 53) years. Among the 196 participants, 118 (60.2%) were female. Most participants were undergraduate BSc nursing students (n=185, 94.4%) and were enrolled in the general nursing program (n=163, 83.2%). Third-year students represented the largest academic-year group (n=60, 30.6%).

Table . Demographic characteristics of the nursing student sample (N=196).

Characteristic and category	Values
Age (y; n=193), mean (SD; range)	22.5 (5.9; 18 - 53)
Sex, n (%)	
Male	77 (39.3)
Female	118 (60.2)
Missing	1 (0.5)
Level of study, n (%)	
Undergraduate (BSc)	185 (98.9)
Graduate nondoctoral (MSc)	11 (1.1)
Year of study, n (%)	
1st year	21 (10.7)
2nd year	46 (23.5)
3rd year	60 (30.6)
4th year	49 (25)
5th year	20 (10.2)
Specialization, n (%)	
General nursing	163 (83.2)
Midwifery	27 (13.8)
Mental health	2 (1.0)
Other	4 (2.0)

Missing responses across questionnaire items ranged from 20.4% to 43.4%, with an overall missingness rate of 31.5%. The proportion of missing responses increased consistently as participants progressed through the questionnaire (Spearman ρ=0.995; *P*<.001), suggesting that some participants may not have completed the survey. Overall, 106 (54.1%) participants completed all 52 questionnaire items. Sensitivity analyses using complete cases and multiple imputation produced similar results; therefore, missing data were not considered to have substantially affected the study findings (Tables S1-S3 in Multimedia Appendix 1).

The final version of the Arabic NURS-DIAL is presented in Table 2. It includes the 5 retained subscales of the NURS-DIAL instrument: mHealth literacy, information literacy, AI literacy, digital well-being, and AI education topics. Each subscale was derived from an existing instrument, with some items modified or eliminated. In total, the final Arabic NURS-DIAL comprised 52 items across the 5 subscales.

XSL•FO
RenderX

All 8 information literacy items were retained for the information literacy scale. Participants responded on a 5-point scale ranging from novice to expert. All 6 mHealth literacy items were retained for the mHealth literacy scale. The responses to this scale were reversed, with higher scores indicating more mHealth literacy. The AI literacy scale was reduced from 16 to 14 items and participants responded on a 7-point scale from strongly disagree to strongly agree. The digital well-being scale was reduced from 6 to 5 items and retained its 5-point novice to expert response scale. Finally, the AI education topics scale was reduced from 20 to 19 items and used a reversed 5-point scale, with higher scores indicating greater importance of these topics.

Table . Final Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL) structure after confirmatory factor analysis (CFA): subscales, item counts, response scales, and items removed.

Subscale	Source	Original items	Final items	Items removed	Response scale
Information Literacy	Martzoukou et al [2] 2023	8	8	None	1 - 5 (Novice → Expert)
mHealth Literacy	Kim et al [16] 2024	6	6	None	1 - 5 (reversed; higher=greater mHealth literacy)
AI Literacy	Wang et al [17] 2023 (expanded)	16	14	AIL_c, AIL_g	1 - 7 (Strongly Disagree → Strongly Agree)
Digital Wellbeing	Martzoukou et al [2] 2023	6	5	DW_e	1 - 5 (Novice → Expert)
AI Education Topics	Civaner et al [18] 2022 (expanded)	20	19	AIE_t	1 - 5 (reversed; higher=greater perceived importance)

The CFA fit indices for the 5-factor Arabic NURS-DIAL model are presented in Table 3. The CFA results provided preliminary support for the proposed 5-factor structure. The model demonstrated acceptable fit according to several indices; however, the standardized root mean square residual (SRMR) exceeded conventional thresholds, and the relatively small sample size in relation to the 52-item model limits confidence in the stability and generalizability of the estimated parameters. The chi-square statistic was significant (χ^2_{1264}=1641.69; P<.001), with a χ^2/df ratio of 1.30.

Table . Confirmatory factor analysis (CFA) fit indices for the 5-factor Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL) model.

Index	Value
χ^2_{1264}	1641.69 (P<.001)
χ^2/df	1.30
CFI[a]	0.930
TLI[b]	0.926
RMSEA[c]	0.055 (90% CI 0.047 - 0.063)
SRMR[d]	0.103
GFI[e]	0.947

[a]CFI: comparative fit index.

[b]TLI: Tucker-Lewis index.

[c]RMSEA: root mean square error of approximation.

[d]SRMR: standardized root mean square residual.

[e]GFI: goodness-of-fit index.

The comparative fit index (CFI=0.930) and Tucker-Lewis index (TLI=0.926) both surpassed the benchmark of 0.90. The root mean square error of approximation (RMSEA) was 0.055 (90% CI 0.047 - 0.063), indicating acceptable fit; however, the SRMR was 0.103, exceeding the conventional ≤0.08 cutoff and indicating that the model did not fully reproduce the observed item covariances. We did not apply post hoc modifications to avoid capitalizing on chance in a modest sample (N=196); the weak-loading items identified in Table 4 (AILkR, λ=0.22; AILeR, λ=0.27; AIEpR, λ=0.36) are likely contributors to the elevated SRMR and are flagged for revision in future validation work. The goodness-of-fit index (GFI=0.947) further supported the adequacy of the specified 5-factor structure for the Arabic NURS-DIAL.

[a]Abbreviated item labels are presented to facilitate interpretation of standardized factor loadings and explained variance. Full item wording in Arabic, original English items, English backtranslations, response options, scoring directions, reverse-coded status, and item retention status are provided in Table S4 in Multimedia Appendix 1.

Table 4 presents the standardized factor loadings and explained variance (R^2) for items across the five Arabic NURS-DIAL subscales. Most items showed moderate-to-high standardized factor loadings; however, several items had weaker loadings and should be evaluated in future validation studies.

The internal consistency reliability of the Arabic NURS-DIAL subscales is presented in Table 5. All domains showed good-to-excellent internal consistency. The Information Literacy subscale (8 items) had a Cronbach α of 0.890, the mHealth Literacy (6 items) and AI Literacy (14 items) subscales each showed good reliability (α=0.856), the Digital Wellbeing subscale (5 items) also had good reliability (α=0.868), and the AI Education Topics subscale (19 items) had excellent internal consistency (α=0.919). Coefficients were computed from all available responses; item-level valid sample sizes ranged from 149 to 156 for Information Literacy, 146 to 149 for mHealth Literacy, 131 to 144 for AI Literacy, 130 to 131 for Digital Wellbeing, and 111 to 129 for AI Education Topics (Tables S1 and S2 in Multimedia Appendix 1).

Table . Internal consistency reliability of the Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL) subscales[a].

Subscale	Items	Valid n per item[b]	Cronbach α[c]	Interpretation
Information Literacy	8	149 - 156	0.890	Good
mHealth Literacy	6	146 - 149	0.856	Good
AI Literacy	14	131 - 144	0.856	Good
Digital Wellbeing	5	130 - 131	0.868	Good
AI Education Topics	19	111 - 129	0.919	Excellent

[a]All α ≥0.70 indicate acceptable internal consistency.

[b]Valid n varied across items within each subscale due to missing data; the range of valid responses per item is reported.

[c]Cronbach α was computed using listwise deletion within each subscale.

Table 6 shows the intersubscale correlations of the Arabic NURS-DIAL and provides evidence of construct validity across the 5 domains. The information literacy subscale was positively correlated with mHealth literacy (r=0.263; P=.001), AI literacy (r=0.218; P=.009), and digital well-being (r=0.507; P<.001), but not correlated with AI education (r=−0.004). There were positive correlations between mHealth literacy and AI literacy (r=0.338; P<.001), digital well-being (r=0.244, P=.004), and AI education (r=0.290, P<.001). This indicates that higher mHealth literacy is somewhat associated with higher AI-related skills and education. AI literacy correlated significantly with digital well-being (r=0.402; P<.001) and AI education (r=0.327; P<.001). Digital well-being was positively related to AI Education (r=0.234; P<.01; small-to-moderate effect size).

RenderX

Table . Inter-subscale correlations for the Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL; construct validity).

Subscale	Information Literacy	mHealth Literacy	AI Literacy	Digital Wellbeing	AI Education
Information Literacy	1.000	0.263[a]	0.218[a]	0.507[b]	−0.004
mHealth Literacy	0.263[a]	1.000	0.338[b]	0.244[a]	0.290[b]
AI Literacy	0.218[a]	0.338[b]	1.000	0.402[b]	0.327[b]
Digital Wellbeing	0.507[b]	0.244[a]	0.402[b]	1.000	0.234[a]
AI Education	−0.004	0.290[b]	0.327[b]	0.234[a]	1.000

[a]*P*<.01.

[b]*P*<.001 (2-tailed).

Table 7 presents the results of exploratory comparisons of Arabic NURS-DIAL subscale scores by sex and year of study. In Table 7, no statistically significant sex differences were found for information literacy, AI literacy, digital well-being, or AI education topics (all *P*>.05), with small-to-moderate effect sizes (absolute Cohen *d*=0.19-0.28). However, female students scored significantly higher than male students on mHealth literacy (female: mean 4.03, SD 0.64; male: mean 3.81, SD 0.64; t_{142}=–2.02, Cohen *d*=–0.34; *P*=.045). Table 8, no significant differences were found across years of study for information literacy, mHealth literacy, AI literacy, or digital well-being (all *P*>.05); however, AI education topics differed significantly by year of study ($F_{4\ 1\ 1\ 4}$=5.91, η^2=0.172; *P*<.001). These findings provide preliminary evidence of known-group validity and should be interpreted as exploratory.

Table . Exploratory comparisons of Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL) subscale scores in the current Saudi validation sample by sex of study[a].

Subscale	Male, mean (SD)	Female, mean (SD)	*t* test (df)	*P* value	Cohen d
Information Literacy	3.00 (0.92)	2.83 (0.87)	1.20 (159)	.23	0.19
mHealth Literacy	3.81 (0.64)	4.03 (0.64)	−2.02 (142)	.045	−0.34
AI Literacy	5.44 (0.95)	5.67 (1.00)	−1.43 (141)	.15	−0.24
Digital Wellbeing	3.68 (0.69)	3.45 (1.02)	1.55 (134)	.13	0.27
AI Education Topics	3.62 (0.58)	3.80 (0.73)	−1.59 (128)	.11	−0.28

[a]Subscale scores are prorated means requiring ≥80% of items.

Table . Exploratory comparisons of Arabic Nursing Digital and AI Literacy Assessment (NURS-DIAL) subscale scores in the current Saudi validation sample by year of study[a].

Subscale	*F* test (df)	*P* value	η^2
Information Literacy	1.34 (4, 141)	.26	0.037
mHealth Literacy	0.81 (4, 127)	.52	0.025
AI Literacy	1.04 (4, 126)	.39	0.032
Digital Wellbeing	1.10 (4, 120)	.36	0.035
AI Education Topics	5.91 (4, 114)	<.001	0.172

[a]Subscale scores are prorated means requiring ≥80% of items.

Table 9 summarizes the internal consistency reliability, standardized factor-loading ranges, and global CFA fit indices for the Arabic NURS-DIAL. All 5 subscales demonstrated good-to-excellent internal consistency. Most items showed moderate-to-high factor loadings; however, several items had weaker loadings. The overall 5-factor model showed acceptable fit on most indices, although the SRMR exceeded the conventional cutoff.

XSL•FO
RenderX

Table . Summary of the internal consistency reliability, standardized factor-loading ranges, and global confirmatory factor analysis (CFA) fit indices for the Arabic NURS-DIAL[a].

Subscale	Final items	Cronbach α	Standardized loading range
Information Literacy	8	0.890	0.63 - 0.90
mHealth Literacy	6	0.856	0.46 - 0.90
AI Literacy	14	0.856	0.22 - 0.90
Digital Wellbeing	5	0.868	0.71 - 0.84
AI Education Topics	19	0.919	0.36 - 0.85

[a]The global fit indices for the 52-item, 5-factor model were as follows: comparative fit index was 0.930, Tucker-Lewis index was 0.926, root mean square error of approximation was 0.055 (90% CI 0.047-0.063), standardized root mean square residual was 0.103, and goodness-of-fit index was 0.947. Detailed comparative fit index results, item-level loadings, and reliability results are shown in Tables 3-5.

Discussion

Principal Findings

This study provides preliminary evidence supporting the Arabic NURS-DIAL as a culturally adapted instrument for assessing digital and AI literacy among nursing students in Saudi Arabia. The findings support content validity; internal consistency reliability; and aspects of structural, construct, and known-groups validity. The implications of the findings should be interpreted considering the study's methodological limitations.

Cross-Cultural Adaptation of the Arabic NURS-DIAL

The Arabic NURS-DIAL was developed through a structured translation and cultural adaptation process, including forward translation, reconciliation, back-translation, expert review, content validation, and student pretesting, in accordance with Beaton et al [15]. The content-validity findings and student feedback support the clarity and cultural acceptability of the Arabic version in this sample. The Arabic and English versions of the questionnaire, English backtranslations, response options, scoring directions, and item-retention status are provided in Table S4 in Multimedia Appendix 1.

The translation and adaptation process is important when assessing digital and AI literacy in Arabic-speaking nursing students. Previous studies in the Middle East and North Africa have explored attitudes toward AI, readiness to use AI, AI literacy, and willingness to use AI. Many of these studies used tools translated from English into Arabic but did not clearly explain how the Arabic versions were culturally adapted or psychometrically tested [9,19]. This study offers preliminary support for an Arabic tool that covers information literacy, mHealth literacy, AI literacy, digital well-being, and perceived AI education needs. Further studies are needed with larger and more diverse groups of Arabic-speaking nursing students.

Structural Validity

The CFA showed initial support for the 5-factor model. Most fit indices were acceptable, but the SRMR was above the recommended cutoff. The 3 retained items AILeR, AILkR, and AIEpR had low loadings. This was related to the higher SRMR. These items need further review in a larger independent sample. No post hoc changes were made because the sample size was limited.

Reliability and Construct Validity

The subscales showed good reliability. Information literacy, mHealth literacy, AI literacy, and digital well-being had good internal consistency, while AI education topics had excellent internal consistency. This means that the items within each section were generally consistent in measuring the same area. These results support the use of the Arabic NURS-DIAL with nursing students for research and low-stakes educational assessment [20,21].

Construct validity was also supported by the relationships between the subscales. Information literacy, mHealth literacy, AI literacy, and digital well-being were positively related, suggesting that students who were more confident in 1 area often reported stronger skills in other digital areas. However, AI education topics showed weaker relationships with the other areas, especially information literacy. This suggests that students' views about what AI topics should be included in nursing education are related to, but different from, their digital and AI skills. Overall, the findings suggest that the NURS-DIAL measures are related but separate areas of digital and AI literacy [22,23].

Known-Group Validity

The known-groups analysis provided early, partial support for the validity of the Arabic NURS-DIAL. Female students scored higher than male students in mHealth literacy, which may suggest that the scale can identify sex-related differences in the use of digital health tools. This finding is consistent with Lupton and Maslen [24], who reported that women often use digital technologies to seek health information and support. However, because this difference was small, it should be interpreted cautiously. No clear sex differences were found in information literacy, AI literacy, digital well-being, or AI education topics. This is in line with Alshowkan and Shdaifat [13], who suggested that sex differences in digital and AI literacy may be decreasing as students have more similar exposure to technology in education.

Students' views about AI education topics differed by year of study. This may indicate that students at different stages of the nursing program consider different AI topics important to their education. Bakarman et al [12] suggested that students may develop a greater understanding of and openness to AI as they gain clinical experience and progress through nursing education.

XSL•FO
RenderX

However, the cross-sectional design did not allow the assessment of changes in students' views over time.

The findings of El Arab et al [9] similarly showed that nursing students and nurses in the Middle East and North Africa generally had positive attitudes toward AI but reported gaps in knowledge, readiness, and experience using AI in clinical practice. In the present study, the Arabic NURS-DIAL identified lower AI literacy in areas related to privacy and the perceived difficulty of learning AI.

Apart from differences in AI education topics by year of study, no other year-group differences were observed. These exploratory findings require replication in larger and more diverse samples.

Implications for Nursing Curricula and AI-Enabled Education

The findings suggest that the Arabic NURS-DIAL may help educators identify areas in which nursing students require further support in digital and AI literacy.

First, the 5 subscales may provide information for educators and curriculum committees about students' strengths and learning needs. In this study, students had lower scores in information literacy, suggesting a need for learning activities focused on searching for information, evaluating information sources, and referencing academic work. Students also showed lower AI literacy in areas related to AI privacy and the perceived difficulty of learning AI. Educational activities addressing the safe use of AI, privacy, and the critical evaluation of AI-generated information may therefore be beneficial.

Second, students in different years of the nursing program had different views about which AI topics were important. AI content can be introduced gradually as students move through the program. Topics such as clinical decision support, ethics, and checking AI-generated information are more suitable for students with more clinical experience. Assessing students at different stages can also help faculty see whether curriculum changes improve digital and AI literacy over time.

There are currently no normative data or validated cutoff scores for the NURS-DIAL. Therefore, scores should be used to identify learning needs and support teaching, rather than for diagnosis, institutional comparison, or high-stakes decisions.

Strengths and Limitations

This study has several strengths. The Arabic NURS-DIAL was translated and culturally adapted using an established framework, reviewed by a multidisciplinary expert panel, and pretested with nursing students. The study also evaluated several psychometric properties, including content validity, structural validity, internal consistency reliability, construct validity, and known-groups validity. In addition, CFA was conducted using an estimator appropriate for ordinal data.

The findings should be interpreted in light of several limitations. The sample was recruited by convenience sampling from 1 university and consisted of undergraduate students in general nursing, which limits generalizability to other institutions, educational levels, specialties, and Arabic-speaking populations. The sample size was also limited in relation to the 52-item, 5-factor CFA model. Therefore, the factor structure should be considered preliminary. Test-retest reliability, criterion-related validity against objective digital or AI competence measures, and measurement invariance across groups were not assessed. Future studies should use multi-institutional and more diverse samples to confirm the factor structure, examine measurement performance across subgroups, and evaluate stability over time.

Conclusions

The findings provide preliminary support for the Arabic NURS-DIAL as a measure of digital and AI literacy among nursing students in the Saudi setting studied. The evidence for content validity, structural validity, internal consistency reliability, and construct validity was obtained. The limited sample size and single-institution design require cautious interpretation. At present, the instrument is most appropriate for exploratory research and formative assessment in comparable settings. Multi-institutional studies are needed to confirm the factor structure and establish its suitability for broader use.

Generative AI Use

Abstract

Background: Nursing records are a critical reflection of nursing practices and play a key role in ensuring the quality of patient care. However, these records sometimes fail to accurately represent the real-world health truth, resulting in information distortion. The manifestations and potential consequences of such distortion remain understudied, which may hinder efforts to improve nursing practices.

Objective: This study aims to explore the primary manifestations and potential consequences of information distortion in electronic nursing records (ENRs).

Methods: We conducted semistructured interviews at a Class-A tertiary hospital in China. A total of 12 nurses from various care units were recruited through purposive and snowball sampling. Inductive content analysis was used to analyze the qualitative data.

Results: Qualitative analysis revealed that manifestations of information distortion in ENRs fall into 4 main categories: untimeliness, inaccuracy, incompleteness, and inconsistency. These categories are further subdivided into 7 subcategories: premature recording, delayed recording, incorrect data entry, fabrication, account misuse, missing data, and inconsistent data entry. The potential consequences of information distortion encompass 3 main categories: patient-related, nurse-related, and data-related. These categories are further subdivided into 5 subcategories: threats to patient safety, increases in negative emotions, damage to professional image, erosion of nursing professionalism, and impairment of secondary data use.

Conclusions: The identified manifestations encompass a wide range of nursing activities, with potential consequences affecting patients, research, and caregivers. Strengthening ethics education, implementing monitoring mechanisms, establishing standardized guidelines, and leveraging technological solutions are recommended to reduce information distortion in ENRs. Further research on contributing factors and effective countermeasures is needed to mitigate information distortion in ENRs.

electronic nursing records; information distortion; information ethics; data quality; nursing

Introduction

Health data reveal personal information about an individual's past, present, or future physical or mental health status [1], playing a vital role in patient treatment, diagnosis, and decision-making [2]. Most health data are stored in health information systems and are reflected in medical and nursing documentation. Nursing documentation represents the care provided and the severity of a patient's condition [3]. Proper documentation serves as a communication tool, quality assurance measure, educational resource, and research material [4,5]. In addition, it is a critical reference for doctors to understand the patient's condition and take appropriate medical actions [6]. Therefore, nurses have a professional responsibility to ensure their records are complete and accurate [7,8].

However, discrepancies between nursing records and actual patient care can be problematic. Some research has found that certain nursing activities are performed but not documented [4,5,9]. De Marinis et al [10] observed that only 40% of nursing activities are recorded in nursing documentation, while Inan and Dinç [11] found that the consistency between actual nursing care and nursing records was only 77.6%. A study measuring health care data quality revealed that every 1% reduction in data completeness resulted in a 1.21% increase in missing events [12], highlighting the need to address data quality issues. In fact, the discrepancies in nursing records constitute some forms of information distortion, which occur when information

XSL•FO
RenderX

documented in electronic nursing records (ENRs) fails to accurately reflect the underlying clinical reality [13]. Current studies focus primarily on constructing various data quality frameworks for health records [14,15]. Although information distortion is closely related to poor data quality and certain data quality dimensions (eg, incomplete documentation and documentation errors) overlap with manifestations of information distortion, it represents a broader ethical and behavioral phenomenon involving multiple forms of deviation and a wide range of contributing factors [16]. However, little research has explored information distortion in practical contexts. Existing studies have focused on isolated manifestations, such as insufficient documentation during nurse rounding or skin assessments [4,5]. A comprehensive understanding of the full spectrum of information distortion in nursing records and its potential consequences is lacking, limiting the development of effective strategies to prevent and mitigate information distortion.

Nursing records can be in paper or electronic formats. With technological advancements, ENRs have become prevalent in health care settings, often replacing paper records either partially or entirely [17]. Therefore, it is crucial to adapt to these changes and explore the manifestations of information distortion within the context of ENRs.

Although China's efforts in informatization started later than those of high-income countries, the Chinese government has actively promoted informatization through policies such as the 14th Five-Year Plan for National Informatization and the High-Quality Development Promotion Action of Public Hospitals. In recent years, the integration of advanced information technologies such as 5G, big data, and the Internet of Things into Chinese hospitals has expanded significantly in both breadth and depth [18]. According to the National Health Commission, the health information technology development index in China reached 74.14 in 2024 [19]. Data from the China Hospital Information Management Association also show that nearly 100 hospitals in China have achieved level 5 or higher in electronic medical record (EMR) adoption. The implementation of information systems such as clinical decision support systems, hospital information systems, EMRs, and picture archiving and communication systems has optimized clinical data management and improved the quality of health care services [20,21]. With the rapid growth of informatization, it is crucial to address information ethics issues to support the sustainable development of these advancements. Examples of such issues include information disclosure, distortion, alienation, and injustice. Notably, information distortion compromises data accuracy, which can directly jeopardize patient health and safety, making it a critical area that requires focused attention [13].

Therefore, this study aims to explore information distortion from a Chinese perspective, specifically examining its manifestations and potential consequences in ENRs. The goal is to enhance the understanding of information distortion and its implications for nursing practice and patient care within the Chinese context.

Methods

Study Design

When exploring social phenomena, qualitative research is suitable [22]. Therefore, a qualitative descriptive design was employed. Semistructured interviews were chosen as they allow for flexible yet guided questions, facilitating an in-depth exploration of participants' thoughts and experiences [23]. All interviews were conducted face-to-face. This study also adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [24] (Checklist 1).

Setting

The study was conducted in a Class-A tertiary hospital in Zhejiang Province, which has been using electronic documentation for nearly a decade. The hospital has over 20 years of experience with electronic documentation and integrated a nursing decision support system into its nursing information system in 2016. Its advanced level of digitalization has provided nurses with a comprehensive technological environment, equipping them with extensive experience in using the system. This experience is invaluable for gaining insights into issues related to information distortion.

Recruitment

The interviewed nurses were recruited using purposive sampling and snowball sampling. To gain deeper insights into the complexities of information distortion, we chose to invite members of the Information Committee to participate in the interviews. Each department has a representative in the committee. These committee members are nurses who are actively engaged in clinical practice while also assuming additional roles, such as addressing system usage concerns and sharing technical expertise with their colleagues. They interact with information frequently, making them more likely to have a deeper understanding of the phenomenon of information distortion. We explained the basic concept of information distortion and the objectives of the research to committee members, allowing them to decide freely whether to participate. Since information systems differ across specialties, we used maximum variation sampling based on departmental categories to ensure that participants represented a broad range of clinical nursing practices. Additionally, committee members were invited to recommend other nurses who had been involved in clinical informatics-related work or projects as potential interviewees. The inclusion criteria for nurses were as follows: (1) clinical registered nurses employed at the hospital for at least 1 year and (2) voluntary participation with signed informed consent. Nurses from other hospitals who were present for training, as well as those absent during the study period (eg, on leave, on vacation, or attending external training), were excluded.

Data Collection

A researcher (JW), a female PhD student trained in qualitative methods, conducted a total of 12 face-to-face semistructured interviews between January 5, 2024, and April 8, 2024. The interviews were conducted in Chinese, either in a coffee shop or in a demonstration classroom within the hospital. Data

XSL•FO
RenderX

saturation was reached when no new insights emerged during the interviews. No other individuals were present besides the participants and the interviewer. The interviewer had no prior relationship with the participants, which helped reduce biases and potential ethical concerns. As part of the interview process, participants completed a short questionnaire about their personal characteristics, including gender, age, education, position, professional title, work experience, and work department. A topic guide with open-ended questions (Multimedia Appendix 1), developed through a review of existing literature and expert opinions and tested by 2 nurses beforehand, was used to cover all relevant topics during the interviews. Participants were asked to describe instances of information distortion they had experienced or observed in their clinical practice, as well as the potential consequences, including those they had witnessed among their colleagues. The interviewer took field notes during the interviews to enhance the data and mark key moments [25]. Interviews lasted between 35 and 91 minutes and were recorded with the written consent of the participants. The audio recordings were transcribed into Chinese by the researcher (JW) and then verified by the participants. No repeat interviews were conducted.

Data Analysis

Inductive content analysis was conducted to analyze the qualitative data, following 3 phases: preparation, organizing, and reporting [26]. Two researchers (JW and YX) independently read the transcripts line by line, noting as many headings as necessary to capture all aspects of the content [27], using NVivo 12 (QSR International Pty Ltd). The headings were compiled into coding sheets, and categories were generated and supported by quotations derived from the interviews. The 2 researchers then compared and discussed each code and category, refining them and adding relevant codes and potential categories as needed. Participants also received a summary of the identified categories along with their own quotations for review, offering them an opportunity to provide feedback on the accuracy of the findings in reflecting their experiences. Finally, the entire research team reviewed and discussed the identified categories and subcategories to ensure coherence.

Since this study is presented in English, analyzing data in Chinese might raise concerns regarding trustworthiness. To address this, a qualified translator first translated the initial transcripts into English. During the process of identifying categories, subcategories, and representative quotations, the bilingual authors (JW and YX) carefully reviewed and adjusted the translations to ensure they accurately captured the intended meanings within the Chinese context in nursing. The other authors then independently reviewed the content for accuracy and provided feedback.

Rigor

The rigor of this study was ensured by the trustworthiness of the data (credibility, transferability, dependability, and confirmability) [28]. Credibility was ensured by having 2 researchers independently code the data, followed by discussions within the research group to resolve any ambiguities or discrepancies. Furthermore, member checks were conducted by inviting participants to review and validate the identified categories and subcategories. Transferability was ensured by providing sufficient contextual information about the information environment in China, enabling readers to relate the findings to their own positions. Dependability was ensured through a detailed description of the participants' inclusion and exclusion criteria, data collection and analysis procedures, and participant characteristics. Finally, confirmability was ensured through regular reflection on the researchers' biases and a commitment to transparency and openness. The researchers also received comprehensive training in qualitative research methods, equipping them with the essential skills and knowledge needed to conduct the study reliably.

Ethical Considerations

This study is part of a larger research project, and ethical approval was obtained from the Ethics Committee of Sir Run Run Shaw Hospital, Zhejiang University School of Medicine (approval number 2024; research number 0270). Prior to the interviews, each participant signed a written informed consent form after full disclosure of the study's aim. All participants were informed that they could withdraw from the study at any time without any obligation. Data analysis and reporting were conducted anonymously to protect participants' privacy.

Results

Participant Characteristics

All participating nurses were women, with an average age of 32 (SD 3.5, range 26 - 37) years and work experience ranging from 4 to 14 years. They worked in various nursing units, including internal medicine, surgery, and the intensive care unit. Participant characteristics are further described in Table 1.

Intensive care unit	1 (8.3)

Manifestations of Information Distortion in ENRs

Overview of Manifestations

The content analysis revealed that manifestations of information distortion in ENRs fall into 4 main categories: untimeliness, inaccuracy, incompleteness, and inconsistency. Seven subcategories were derived: premature recording, delayed recording, incorrect data entry, fabrication, account misuse, missing data, and inconsistent data entry. In addition, we identified specific nursing contexts in which these manifestations are more likely to occur, including observation and assessment, planning and evaluation, technical intervention (preventive and curative), educational intervention, incident management, and charges management. The findings are synthesized in Figure 1.

Figure 1. Manifestations of nurses' information distortion in electronic nursing records.

XSL•FO
RenderX

Untimeliness

This type of manifestation occurs when nurses write ENRs at inappropriate times. This category is subcategorized into 2: premature recording and delayed recording.

Premature Recording

Nurses indicated that they would record times before the events actually occurred. Nurses stated that they might complete the assessment forms and nursing care plans before actually checking patients.

> *Some people have a habit of copying the assessment forms and care plans for their patients in advance, then doing rounds to check the patients. Then, they go back and make changes. With so many patients, it could take an hour to finish, but they don't change the recorded time on the computer.* [N3]

Another nurse stated that she recorded the time earlier than the actual time when performing interventions, such as infusing blood:

> *We have drip rate requirements for blood transfusions, for red blood cells, it's 60 drops per minute, and there's a formula to figure out when it should be done. But sometimes, with all the factors affecting the tubing, it's impossible to meet that exact time, so I'll close the loop in the PDA (Personal Digital Assistant), you know, I have to mark it as finished in the record, even though it's still infusing.* [N7]

Nurses also stated that the education time was sometimes earlier than the actual time:

> *We sometimes check off the education part when the medical order is issued, then give the education, like providing education when we're actually giving out the medication. So the timing isn't quite right.* [N5]

Delayed Recording

Nurses mentioned that they might also record event times later than they actually occurred. A nurse said that they might forget to assess or give care plans and make up for it later:

> *There are so many things, so sometimes I forget to update the assessments or the care plans. Then, right before leaving, I'll check and go, 'Oh no, I missed that', and quickly fill it in.* [N1]

Nurses also explained that this happens during curative interventions. When they administer medication while awaiting a delayed doctor's order, they give the medication first and document the time afterward to comply with regulations. One nurse said the following:

> *We (with doctors) agreed to administer 8 units of insulin, but the doctor's order only specifies 6 units. We might ask the doctor to update the order to add the extra 2 units later. However, you might end up administering the insulin before the order is updated and yet the time on your records looks perfect.* [N3]

In educational terms, in addition to premature recording, nurses mentioned that they might sometimes delay recording:

> *When the meds are prescribed, they pop up one by one, and I can't just sit there and watch each one to check it off, right? So I'll catch up on it later. Like, I might go through all the education items from the morning at noon. I don't care what time they were ordered—7, 8, 9, or 10 o'clock—I just check them all off at once.* [N2]

Inaccuracy

This type of manifestation indicates that the contents of ENRs cannot reveal the truth. This category is further divided into 3 subcategories: incorrect data entry, fabrication, and account misuse.

Incorrect Data Entry

There are times when events described in ENRs do not accurately reflect the truth. When assessing the patient's condition, some issues may arise, such as errors in location. Some nurses noted:

> *Once during a tube assessment, when I took over from another nurse, I found out that for nearly half a month, the record said the tube was in the left nostril when it was actually in the right one.* [N1]

Nurses also mentioned that they would intentionally assess the patient's condition as more severe to alert doctors:

> *To use restraints, we need a doctor's order. Before the doctor gives the order, the patient's risk score has to be pretty high. So we might rate them higher than actual to make sure they get the restraints.* [N12]

Nurses also found that the nursing care plans they create are sometimes not suitable for patients, and their evaluation faces similar issues. One nurse noted:

> *In fact, some of patients even know more than we do, but we still put down "knowledge deficit" (when making the nursing care plan)…While the patient is in the hospital, it's rare for us to mark nursing evaluations as "completed." We usually just keep marking 'partially completed' until they're discharged, even if they no longer have the issue.* [N3]

When performing preventive interventions, nurses mentioned that they choose to continue providing nursing care for patient safety even after the order had been discontinued:

> *For example, at 9 o'clock, the doctor's restrictive order expired. We documented in our nursing records that we stopped the restriction, but in reality, we kept enforcing it to keep the patient safe, without asking the doctor to renew the order.* [N12]

Educational templates offer convenience by significantly reducing nurses' workloads. However, they can lead to errors if nurses fail to apply their own judgment. One nurse said the following:

> *We have a template for VTE (venous thromboembolism) discharge education, it should be adjusted based on the patient's needs. However, we often use it without any change…Like the template*

XSL•FO
RenderX

suggests quitting smoking but the patient doesn't even smoke. [N6]

Additionally, nurses mentioned that when they have reported an incident, such as a pressure ulcer, they may not be able to confirm that it has healed. One nurse said:

I think pressure ulcers are also a problem. We may think they have healed, but the assessment forms are still filling up, no one records "healed." [N6]

Regarding charges, nurses admitted that they sometimes intentionally overestimate a patients' condition to increase their incomes:

We sometimes score the Braden scale at 18 or below on purpose so we can charge for it, as only scores of 18 or below qualify for high-risk pressure ulcer fees. For some patients who have undergone ERCP (Endoscopic Retrograde Cholangiopancreatography), their actual scores might be above 18, but we score them lower to fit the charging criteria. [N1]

Fabrication

There have been instances in which nurses documented tasks in ENRs that were not actually performed. Under the pressure of excessive workloads, some nurses may resort to fabricating their observation records for convenience:

For critical care charts, we have to record data every hour. Sometimes if we're really busy and the patient seems fine, we'll just fill in that hour based on other times. [N9]

If I'm in charge of rooms 9 to 16, I'll record the same position for everyone in those rooms at a certain time. Like at 10 o'clock, they all 'left side'. And at 12 o'clock, they all 'right side.' [N4]

Moreover, nurses highlighted that fabrications are more common in their education records:

Education problems are pretty big. When handing out oral medications, there are too many medications, like a dozen or more. We might miss the education step, we don't explain what the new medications are for, we just focus on checking the patient's identity, even though the records show that we provided the education…We just don't have the time or energy to explain what the basic prevention measures for VTE include and what needs to be done. But the records do show that we provided education on VTE prevention. [N2]

Account Misuse

Nurses have their own accounts on ENRs and personal digital assistants, and misuse of these accounts can sometimes occur. One nurse said:

Some people don't log out of the PDA after their shift, and sometimes I don't check carefully. So I might use the PDA all day with the previous shift's account. All the charges and records for the day end up under their name. [N11]

The hospital has specific rules for correcting records, allowing only nurse leaders to make changes after 24 hours have passed. However, nurses often use their leaders' accounts to make corrections without informing them.

We all know our leader's code. Sometimes, if there's a mistake in the record, we use the leader's code to make corrections. [N4]

Incompleteness (Missing Data)

This type of manifestation indicates that the content of ENRs is less comprehensive than the actual nursing activities performed. This category consisted of a single subcategory: missing data.

Nurses stated that they tend to omit records either intentionally or unintentionally. One nurse mentioned that she did not record her thoughts during assessment because her experienced colleagues did not write them down:

They (experienced nurses) didn't write it, so maybe it's not necessary. [N3]

Nurses also stated that new nurses are especially more likely to miss data. One nurse described this issue when discussing the nursing care plan:

Some less experienced nurses, for example, might focus all their efforts on bringing down a patient's fever after the patient has had it for a day. But they might forget to include the issue of the high temperature in their documentation. [N8]

When performing technical interventions, nurses also acknowledged that they sometimes omit certain details from documentation.

When an infusion gets interrupted, you usually don't really pay attention to it. If a patient needs to go for a test and there's half a bag of saline still hanging, you won't remember to mark it as interrupted. [N2]

Incident management helps prevent error recurrence and improve care quality [29]. However, nurses tend not to report medication errors:

In our oncology unit, patients receiving chemotherapy also get an anti-nausea medication like ondansetron every 8 hours. For instance, if it's given around 11 or 12 in the morning, we prioritize using the gastroprotective medication before chemotherapy. But with so many other medications to give throughout the day, sometimes as late as 10 or 11 at night, the timing for that small dose of ondansetron gets pushed back. It's actually a near miss, but we don't report it. [N6]

When it comes to charges, nurses stated that their established work habits sometimes lead to omissions in documentation.

Our work habit is to charge for services in the morning. So, if a nebulizer treatment starts around noon, we won't charge for that day, just once. In this case, a mask is given for that day, but no fee is collected. [N1]

XSL•FO
RenderX

Inconsistency (Inconsistent Data Entry)

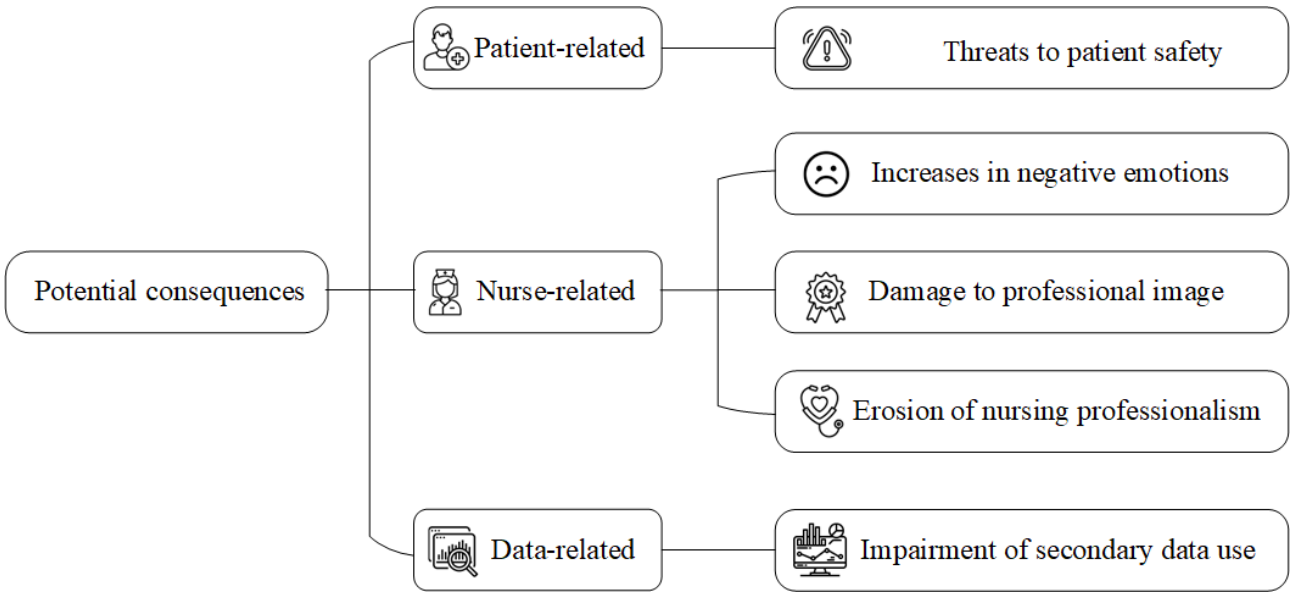
This type of manifestation refers to contradictions in data within ENRs. There may be disagreement between data in ENRs or between ENRs and another data source such as EMRs. This category consists of one subcategory: inconsistent data entry.

The lack of interoperability could hinder health professionals from exchanging information. Nurses stated that insufficient integration of information systems across different departments or systems could lead to inconsistent data in assessment. The lack of standard medical codes could lead to data recorded about the same patient having different descriptions:

> *This patient was transferred from the ER (Emergency Room) to our ward, but I can only find his medical records by checking the discharge notes. If I look in our system, there's nothing there, it's like I'm dealing with a new patient.* [N1]

> *There are situations where the doctor and we nurses both assess the patient, but we record different chief complaints. The doctor might write "diagnosed with pancreatic cancer over seven months ago," while we write "a few days post-chemotherapy."* [N7]

In addition, the introduction of data capture technologies, which make nursing practices more labor-saving and effective, can sometimes also lead to inconsistencies with manually entered records. Nurses expressed this issue during curative interventions:



> *If a patient's oxygen saturation drops, we handle the situation first and document it later. But vital signs are updated periodically, so while you might note the low oxygen levels, the recorded vital signs at that time could show normal, creating an inconsistency between the two.* [N7]

Potential Consequences of Information Distortion

Overview of Potential Consequences

The data indicated that the possible consequences of information distortion could be classified into 3 categories: patient-related, nurse-related, and data-related. These can be further divided into 5 subcategories: threats to patient safety, increases in negative emotions, damage to professional image, erosion of nursing professionalism, and impairment of secondary data use. The findings are synthesized in Figure 2.

Figure 2. Potential consequences of information distortion in electronic nursing records.

Patient-Related: Threats to Patient Safety

Nurses indicated that failing to document changes in a patient's condition could impact both nurses' and doctors' judgments about the patient. Inaccurate or omitted documentation may obscure the patient's true clinical status, delaying the recognition of deterioration and the timely escalation of care, which may ultimately result in delayed treatment. Furthermore, distorted documentation may contribute to medication errors by leading clinicians to misjudge the patient's condition and make inappropriate clinical decisions, thereby posing significant risks to patient safety.

> *We often rely on the critical care sheet or assessment sheet to track significant changes in a patient's condition. If our previous records aren't accurate, it will definitely affect how we judge the patient's condition later, right? We wouldn't know when the changes actually started, and this could throw off our focus.* [N10]

> *If a patient's blood pressure reads 180 but he's shivering, and you only record the high blood pressure and inform the doctor, the doctor will trust that data and might prescribe other medications. If they prescribe a blood pressure med, like oral nitroglycerin, and you give it to the patient who's actually shivering, which could mean they have an infection, right? If they're in septic shock, their blood pressure would already be dropping. Giving them a blood pressure medication could be really dangerous.* [N5]

XSL•FO
RenderX

Nurse-Related

Increases in Negative Emotions

Nurses expressed that the appearance of information distortion could make them feel regret or upset, intensifying their negative emotions.

> *(If I don't have the information distortion) I won't be regretting at home that I didn't write accurate records, thinking about what I should have done at that time.* [N6]

> *If they find my record is distorted, I'll definitely feel a bit down about it. I mean, who doesn't want their records to be perfect?* [N12]

Damage to Professional Image

When information in the records does not match the actual situation, the likelihood of medical disputes may increase, and patients' trust in nurses may decline, affecting nurses' professional image.

> *If there's a problem with the drug's expiration and patients notice it, especially if it says something like "12 hours", it can cause a medical dispute cause issues. And patients might feel they can't fully trust we nurses, thinking, 'How could they make mistakes on something like this?'* [N8]

Erosion of Nursing Professionalism

Constantly distorted information can desensitize nurses, causing them to overlook important possibilities. This can erode nursing awareness and expertise, ultimately undermining the thoughtful and conscientious spirit essential to the profession.

> *Many patients, including those who've had surgery, often have a care plan for a long time before they're discharged. We rarely make any changes, so there's hardly any real awareness of their care needs.* [N4]

Data-Related: Impairment of Secondary Data Use

Secondary data use refers to the use of data for purposes other than those for which it was originally collected, such as quality improvement or research analysis [30]. As ENRs become increasingly prevalent in clinical practice, secondary analysis of these data is also commonplace. In terms of incident management, nurses expressed that distorted information about the cause of an incident can introduce bias in quality improvement, leading to ineffective improvement measures. As a result, incidents may continue to occur, rendering significant efforts futile.

> *Because this (incident reporting) involves the subsequent analysis, why did this unexpected event happen? Were your measures effective? I think it is necessary to restore the actual situation. For example, if I say I put a restraint mitt on the patient but they still pulled out the tube, during analysis, wouldn't they think that even with the mitt, the patient could pull out the tube? But if the mitt was not actually used, then maybe if it had been, the patient wouldn't have pulled out the tube. Without an accurate record of the real situation, you can't analyze the reason properly.* [N12]

From a research perspective, nurses noted that distorted records could undermine the validity of findings generated from such data, ultimately compromising the reliability of scientific research.

> *If I'm working on a pressure ulcer risk prediction model, things like how long a patient stays in bed or how often their position is changed are key factors. If those records aren't accurate, they will affect the model's accuracy. In that case, what's the point of developing such a model?* [N7]

Discussion

Principal Findings

This research is the first to clearly identify manifestations of information distortion in ENRs. Although previous studies do not explicitly use the term "information distortion," some specific manifestations of distortion have been explored, including failure to record in a timely manner [31,32], inaccurate data [30,33], nursing practices performed but not recorded [4,5], and discrepancies in the same information [34]. These findings are related to our results, which include manifestations of delayed recording, incorrect data entry, missing data, and inconsistent data entry. Our study further contributes by adding manifestations of premature recording, fabrication, and account misuse within the context of Chinese nursing. Some of the identified manifestations raise ethical and professional concerns, as they may undermine the principles of accountability, responsibility, and expertise outlined in the International Council of Nurses Code of Ethics for Nurses [35]. Structured ethics education and training are needed to strengthen nurses' awareness of accurate and responsible documentation practices. In addition, real-time documentation monitoring systems could be developed to provide oversight and support early identification of documentation-related issues. However, it is important to recognize that not all instances of information distortion represent intentional misconduct. For example, some behaviors identified in this study, such as overassessment and continued restrictions, were driven by nurses' intentions to enhance patient safety, even when this required them to assume additional responsibilities. Therefore, considering the complexities of the clinical context in which these behaviors occur, it is inappropriate to see the issues in black and white.

Another important finding is that manifestations of information distortion permeate almost every facet of nursing practice, which is concerning. Previous studies have explored manifestations of information distortion in various nursing contexts, including assessments, evaluations, technical and educational interventions, and incident reporting [5,10,36]. Our study expands on this by identifying information distortion in nursing care plans and charge management, which may be related to the hospital's comprehensive electronic nursing systems, which provide nurses with more intuitive user experiences. In our interviews, participants from every department reported experiencing or witnessing information distortion in ENRs, suggesting that this issue is not limited to specific departments,

XSL•FO
RenderX

such as those that are extremely busy or poorly managed. Considering the widespread occurrence of information distortion, standardized documentation guidelines tailored to different nursing contexts are needed. In addition, review and feedback mechanisms should be established not only through hierarchical supervision but also through peer-to-peer feedback to improve documentation quality.

We also found that the potential consequences of information distortion in ENRs affect patients, caregivers, and the secondary use of data. Some studies on data quality have pointed out that incomplete or inaccurate data can put patients' health care at risk [37] and affect the reuse of data for analysis [38,39], which is consistent with some of our findings, including threats to patient safety and impairment of secondary data use. Our research further explores the nurse-related potential consequences, offering an example of the impact of information distortion on health care professionals—an area seldom investigated in previous studies. Future studies could further develop and refine frameworks for understanding potential harms associated with health data based on these findings [40].

Although the issue of information distortion has existed since the era of paper-based records, manifesting in behaviors such as reluctance to report incidents or falsification of records, some of the manifestations identified in this study suggest that advancements in information technology may be influencing this phenomenon. Examples include the "copy then adjust" habit, the inappropriate use of templates, and the misuse of accounts, which may align with Burnum's perspective that the development of health information technology, such as electronic health records, has not improved the quality of recorded data; instead, it has resulted in the recording of a larger amount of poor-quality data [41]. However, the trend toward greater digitization is irreversible. Given the pervasive manifestations of information distortion and the severe potential consequences, further research is needed to explore the influencing factors and develop strategies to address information distortion in ENRs, with the ultimate aim of enhancing the quality of records. Our research has highlighted factors such as heavy workload, years of experience, lack of interoperability, and the absence of standardized medical codes, which align with existing literature [34,42]. Potential countermeasures, such as the adoption of AI scribes and improvements in interoperability among electronic health record systems, could be considered to reduce information distortion [43]. Further research is needed to explore more related factors and countermeasures based on our findings.

Limitations

This study has several limitations. Although the sample size may appear small, data saturation was achieved, which is consistent with the typical range of 12 to 20 interviews required for qualitative research [44]. Although nurses were recruited from diverse departments, the study was conducted in a single hospital in China, and the findings may have been influenced by its specific organizational and cultural context. Nevertheless, this study provides valuable exploratory insights into information distortion, highlighting potential trends that can be further explored in multicenter studies to strengthen generalizability. Furthermore, the findings were based on participants' self-reported experiences. Because the interviews explored ethically sensitive documentation practices, participants may have underreported or minimized problematic behaviors due to social desirability bias, despite assurances of confidentiality. Their willingness to disclose such practices may also have been influenced by organizational culture and workplace norms. In addition, this study relied solely on interview data and did not incorporate methodological triangulation, such as direct observation or document analysis. Future research using multiple data sources could provide a more comprehensive understanding of information distortion in ENRs. Finally, all participants were female, and some were purposively recruited for their informatics-related experience. While these participants provided rich insights into electronic nursing documentation, their perspectives may differ from those of nurses without such experience, potentially limiting the applicability of the findings to the broader nursing population. Nevertheless, given the predominance of female nurses in the Chinese nursing workforce, the lack of male participants was difficult to avoid. Moreover, we included nurses with limited informatics-related experience, and purposive sampling was adopted to maximize variation in informatics experience and departmental backgrounds, thereby enriching the breadth and depth of the data.

Conclusions

This research identified 4 main categories of information distortion manifestations in ENRs and 3 categories of their potential consequences. These findings underscore the importance of raising awareness of information distortion in health care data. Ethics training, monitoring mechanisms, standardized documentation guidelines, and technology-enabled solutions are recommended to address this issue. Further research is needed to analyze the contributing factors and develop effective countermeasures to improve the quality and reliability of nursing records.

Acknowledgments

The authors sincerely thank all the participants for their time and valuable contributions. No generative AI tools were used in the preparation of this manuscript.

Funding

This work was supported by the Health Commission of Zhejiang Province (grant number 2024KY1142) and by the China Scholarship Council program.

Abstract

Background: Evidence-based practice is essential for delivering safe, high-quality nursing care; however, its implementation remains challenging due to barriers such as limited knowledge, a lack of supportive organizational culture, and insufficient access to relevant knowledge at the point of care. Knowledge management systems (KMSs) have the potential to bridge this gap by integrating evidence into the nursing process through technological support. Despite growing interest, the integration of KMS into daily nursing practice is still underexplored, especially from the perspective of frontline nurses.

Objective: The aim of this study was to explore nurses' perspectives on the requirements for a KMS that supports evidence-based practice at the point of care, with a focus on usability, process integration into the electronic nursing care plan and patient chart, and implementation challenges and benefits.

Methods: A qualitative study was conducted in a Swiss hospital using observations, focus groups, and individual interviews with 6 registered nurses, 9 advanced practice nurses, 2 nursing managers, and 1 head physician. Data were analyzed using thematic analysis.

Results: The analysis revealed four main categories and ten subcategories: (1) content of the KMS, (2) personal and structural factors of knowledge management, (3) technical conditions of the KMS, and (4) implementation of a KMS. Participants emphasized the need for an intuitively structured, process-integrated system that links evidence-based information directly to nursing interventions in the electronic nursing care plan and patient chart. Organizational support, interprofessional collaboration, and clear responsibilities were identified as critical for successful implementation.

Conclusions: There is a clear need for a KMS that is user-friendly, seamlessly integrated into clinical workflows, and supports quick, reliable access to evidence-based knowledge. A KMS could enhance nurses' access to reliable knowledge, promote evidence-based decision-making, and strengthen professional confidence at the point of care. By embedding evidence directly into the electronic nursing care plan and patient chart, such systems can streamline workflows, reduce time spent searching for information, and support more consistent application of best practices. These capabilities may improve information retrieval and contribute to a safer, more consistent nursing practice.

KEYWORDS

evidence-based practice; knowledge management; knowledge management system; qualitative research; point of care; nursing

Introduction

Background

Delivering safe, high-quality patient care is a central goal of health care institutions [1] and evidence-based practice (EBP) plays a key role in achieving this [2]. Despite strong advocacy, the integration of scientific evidence into everyday nursing practice remains inconsistent [3]. Studies report that barriers such as insufficient EBP knowledge and skills, lack of mentors and facilitators, perceptions that EBP takes too much time, unsupportive organizational cultures, and environments hinder nurses from using evidence at the point of care [2,3]. At the same time, there is an exponential growth in the body of evidence-based knowledge, which needs to be accessed and integrated into daily nursing practices in a timely and contextually relevant manner [4].

To address these challenges, the concept of knowledge management, widely used in other industries, is gaining traction

XSL•FO
RenderX

in health care settings [5]. Knowledge management refers to programs or systems to create, capture, store, organize, and share knowledge and information effectively within organizations [6]. In health care settings, knowledge management has the potential to strengthen nursing performance [7] by facilitating access to both scientific knowledge and the expertise or practice knowledge of team members [5]. However, effective knowledge management in nursing practice requires more than just access; it requires integration into clinical workflows, supportive leadership, and a culture of continuous learning [6,8].

Knowledge management systems (KMSs), as a technological solution, offer a way to embed both evidence-based and practice-based knowledge directly into the nursing process [4]. KMSs are designed to support and enhance organizational processes for creating, storing, retrieving, transmitting, and applying knowledge [9]. When effectively designed and implemented, KMSs can support nurses in making informed decisions, promote EBP, and improve the quality of nursing care [9,10]. Despite this potential, research shows that such systems are rarely used in health care, especially in nursing contexts. To date, there are few descriptions of the development, implementation, and evaluation of KMSs in nursing practice [4]. There is a need to investigate factors on the adoption of a KMSs that are integrated into the nursing process in hospitals from different perspectives [11].

Prior Work and Research Gap

In a prior study, Ranegger et al [12] demonstrated the theoretical feasibility of linking evidence-based knowledge to standardized nursing interventions through a mapping project. While this work provided an essential foundation for embedding evidence in structured nursing documentation, it did not explore how such a system could meet the practical and contextual needs of nurses in clinical settings. Consequently, little is known about what nurses expect from a KMS, how they envision it supporting their workflow, and which organizational factors are required for successful implementation [12].

Aim of This Study

Building on this gap, our study focuses on advancing current research on KMSs in the health care sector by adding a user-centered perspective to support nurses at the point of care.

Therefore, the aim of this study was to qualitatively explore nurses' perspectives on the requirements for a KMS that supports EBP at the point of care, with a focus on usability, process integration into the electronic nursing care plan and patient chart, and implementation challenges and benefits. By identifying these requirements, this study contributes to the development of a KMS that is not only theoretically feasible but also contextually relevant, usable, and sustainable in clinical practice.

Methods

Study Design

An exploratory qualitative study design based on inductive thematic analysis was conducted to gain an in-depth understanding of nurses' perspectives, expectations, and experiences related to the development and implementation of a KMS to support EBP at the point of care. The study followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines to ensure methodological rigor and transparency [13]. The study was underpinned by a pragmatic theoretical orientation, which assumes that knowledge is constructed through experience and that research should focus on understanding real-world problems and generating practical solutions. This framework guided the exploration of nurses' expectations of a KMS, emphasizing the practical relevance of the findings for system design and implementation.

Researchers' Characteristics

Two researchers collected the data. The first researcher was a female research associate with expertise and training in nursing and health sciences. She holds a master's degree in public health, is specialized in EBP, and has worked as a nurse previously. The second researcher was a male research associate with a master's degree in information systems with research experience in digital health. The researchers were not known to the participants before the study. Participants were informed about the researchers' professional backgrounds, institutional affiliations, and the aim of the study. They also knew about the researchers' roles within the project and that participation was voluntary and anonymous. The researchers were aware that their professional backgrounds could influence how they collected and analyzed data. They therefore reflected these potential biases throughout the analysis to support a balanced understanding of the data.

Participants and Setting

The study was conducted in a hospital in Switzerland that is part of a private hospital group comprising 3 hospitals. The hospital group employs approximately 2500 staff and treats over 140,000 patients annually, including around 27,000 inpatients. At the time of the study, a new intranet was planned to centralize knowledge resources and improve search capabilities.

The study focused on nurses with diverse work experience and role profiles because the KMS was intended primarily for nursing practice. Additionally, 1 physician was included to provide an interprofessional perspective, as physicians are involved in the current system. Only 1 physician was included because the study primarily focused on nursing workflows and physician involvement in the planned KMS was limited during the recruitment period. A purposive sampling strategy was applied via the head of the nursing development department to recruit participants for observations, individual interviews, and focus group interviews. All participants were directly or indirectly involved in nursing-related knowledge management, either as users of or contributors to knowledge sources. Eligibility criteria included active involvement in nursing care or related managerial or educational functions within the hospital. The initial plan was to invite 15 to 20 participants, which was achieved, with 18 individuals confirming attendance.

XSL•FO
RenderX

Data Collection

Prior to data collection, an observation guide and a semistructured interview guide were developed based on a literature review. The researchers first conducted independently 4 hours of open, participatory observation on a ward in November 2023, focusing on the activities of 3 registered nurses during their shifts on a surgical and internal medicine ward and took field notes according to the observation guide. These 3 nurses were not further part of the interviews.

Subsequently, all interviews were conducted using the semistructured interview guide, which was adapted after the observations. The 2 authors held 2 face-to-face focus group interviews in the hospital, with participants grouped by professional hierarchy to encourage open discussion. The first focus group involved 9 advanced nurse practitioners (ANPs) with master's degrees from different wards in the participating hospital (92 min). The second focus group comprised 3 registered nurses with a diploma degree from the surgical ward to capture another perspective (50 min). Three additional online interviews using Microsoft Teams (30 min each) were held with a head physician, a division manager in nursing care, and a co-nursing manager to include different viewpoints. Sociodemographic data from all participants were collected verbally (Table 1). All interviews were conducted between November 2023 and January 2024 and were audio-recorded. Field notes were taken during the interviews. No repeated interviews were carried out.

Table . Sociodemographic characteristics (N=18).

Sociodemographic characteristics	Value
Sex, female, n (%)	18 (100)
Role, n (%)	
Advanced practice nurse	9 (50)
Registered nurse	6 (33.4)
Nursing management	2 (11.1)
Physician	1 (5.5)
Field of work, n (%)	
Surgical	8 (44.4)
Internal medicine	5 (27.8)
Other (eg, orthopedics and oncology)	3 (16.7)
Expert in a field (eg, delirium and breast care)	2 (11.1)
Years of working experience, n (%)	
<5	1 (5.5)
5-10	7 (38.9)
10-15	5 (27.8)
>15	5 (27.8)

Observation notes were translated, summarized, and thematically clustered. The single and focus group interviews were audio-recorded and transcribed by hand. Data analysis took place in parallel with data collection. Data saturation was considered achieved after the third online interview. Consistency between the 2 data collectors was ensured through continuous discussion during data collection and analysis to align interpretation and maintain reflexivity.

Data Management and Analysis

Thematic analysis was conducted following the 6-phase approach described by Braun and Clarke [14]. In addition to the categories already formed a priori through a literature review and by developing the semistructured interview guide, 1 author performed the initial coding of all transcripts using MAXQDA 2022 [15]. Coding decisions and theme development were subsequently discussed with 2 additional authors to ensure analytic consistency and to confirm the relevance of identified categories. Disagreements were resolved through discussion until consensus was achieved. The analysis resulted in main categories and subcategories, which were then translated from German to English.

Ethical Considerations

All participants were informed verbally about the purpose and procedures of the study, data confidentiality, and voluntary participation. Informed consent was obtained before participation, and withdrawal of consent was permitted at any stage, including after data collection. Audio recordings were transcribed verbatim, anonymized to remove any potentially identifiable information, and assigned participant codes before recordings were subsequently deleted. All data were stored securely on password-protected institutional servers in accordance with data protection regulations. No participants withdrew consent for the use of their data in this study. According to Swiss legislation, this study did not require approval by a cantonal ethics committee. In accordance with the Swiss Human Research Act (Humanforschungsgesetz, HFG),

ethical approval is mandatory only for research involving human participants where health-related personal data are collected or where interventions are performed [16]. The present study focused exclusively on healthcare professionals' perspectives on KMSs. No patients were involved, no health-related personal data were collected, and no interventions were performed. Therefore, the study does not fall within the scope of the Swiss Human Research Act and did not require formal ethical approval by a Swiss ethics committee.

However, the study was followed in accordance with the World Medical Association's Declaration of Helsinki.

Results

Sociodemographic Characteristics

All 18 participants were nurses with different degrees and roles, except 1 was a head physician. The participants from the observations and interviews had at least 1 year of professional experience and worked in different roles and fields in the hospital (Table 1).

Categories

The thematic analysis resulted in 4 main categories with 10 subcategories, each of which will be discussed in the following sections (Table 2).

Table . Main categories and subcategories of the thematic analysis.

Main categories	Subcategories
Content of KMS[a]	• Information sources • Format of information
Personal and structural factors of knowledge management	• Information retrieval skills • Time pressure and efficiency
Technical conditions of KMS	• Integration into workflow • Knowledge access and architecture
Implementation of a KMS	• Barriers • Facilitators • Expected benefits • Potential quality indicators

[a]KMS: knowledge management system.

Content of KMS

Information Sources

Participants described a clear distinction in information sources used by different roles. At the point of care, registered nurses primarily relied on in-house nursing instructions and team members, which was also observed.

In contrast, ANPs accessed a wider range of formal evidence sources, including databases, guidelines, professional networks, and conferences, which they used to update or develop new nursing instructions. Although digital advancements were mentioned, none of the participants reported using artificial intelligence (AI) tools in their knowledge work. Instead, maintaining clear, up-to-date, and evidence-based nursing instructions was viewed as a central way to ensure consistent practice. Most ANPs and nurses from focus groups would support the inclusion of brief synopses of studies explaining changes and evidence updates in the in-house nursing instructions. These would offer nurses an optional, deeper insight into the rationale behind changes. However, some ANPs and the co-nursing manager were critical of this and questioned whether nurses at the point of care would be using this due to the high workload and limited skills in scientific working.

Format of Information

Participants acknowledged that the current nursing instructions were logically structured and helpful, often featuring tables of contents and uniform formatting. Nurses were instructed to use nursing standards as the main source of information in nursing practice. At the time point of the interviews and observations, it was therefore important that the nursing standards were written in simple language and regularly updated according to the latest evidence.

Registered nurses and ANPs from both focus groups and observations expressed a need for varied formats as a source of information, such as checklists, videos, and schematics, as long as the content remained concise and practice-oriented. The information in the KMS should not be overloaded and it should summarize the most important information as briefly as possible, as an ANP said:

> *I think you have to be careful not to overload nurses with information, to be honest. You have to focus on what you really need in practice. The more it is broken down to the practical situation, the more the knowledge is used.* [P1]

Personal and Structural Factors of Knowledge Management

Information Retrieval Skills

Participants reported that while they were able to locate nursing instructions within their own specialty, accessing materials outside of their immediate practice area was often time-consuming and frustrating. Nurses, particularly those who

XSL•FO
RenderX

were new, part-time, or less experienced, struggled to find information when documents were not intuitively filed or when search paths were long and complex. A nurse confirmed this during the observation. Many participants noted that there was no systematic onboarding to teach information-seeking or navigation strategies. Although some suggested additional training, they emphasized that intuitive structure and powerful search functions were more impactful than teaching workarounds. An ANP summarized it as follows:

> *If the search function is poor, it doesn't matter how well you know the system. You still can't find what you need.* [P2]

Time Pressure and Efficiency

Time constraints were a significant concern in information use and acquisition across all participants. Nurses commonly relied on team members and ANPs to obtain information quickly, particularly during high workload periods. In the observations, the nurses asked more experienced nurses or a physician in some cases before searching available documents. All participants would find it helpful to have faster access to information sources at the point of care. These sources should be process integrated, which means embedded in the electronic nursing care plan and patient chart. An ANP said:

> *I often hear that nurses know that a certain nursing instruction exists. They still ask me as an ANP if I can't just tell them the answer quickly so that they do not have to search for the document.* [P1]

Technical Conditions of KMS

Integration Into Workflow

Participants envisioned a KMS integrated into every phase of the nursing process, from patient admission and assessment to diagnosis, intervention, and evaluation. They found it important that the information would be available and could be retrieved exactly when they needed it. The nurses from the focus groups saw the greatest benefit in linking information to nursing interventions, for example, to check how a central venous catheter needs to be connected. The head physician also recognized potential in areas like diagnosis support and medication information:

> *For example, if I select permanent catheters in the nursing care plan, the relevant nursing instruction should be stored there. If access to the information is clearly visible in the nursing care plan, my attention would be drawn to it and I can just click on it. And then the information just comes up. Because if it is not obvious and I don't see it, I won't click on it and won't get to the information. It has to be obvious to me.* [P5]

Knowledge Access and Architecture

All participants criticized the current dual document storage system, which resulted from an ongoing transition to a new intranet. Most participants found the folder structure confusing and the search function ineffective due to a lack of semantic features. Old or irrelevant documents still appeared in search results, adding to the inefficiency. An ANP mentioned:

> *With the folder system, for example, there are folders from the pharmacy, where I think there is a great need for training. Because sometimes you go to an instruction but do not realize that there is also something about [eg,] potassium substitution. And there would be very helpful practical [nursing] instructions. But [most nurses] do not know that they exist.* [P2]

Suggestions from the participants were to install links in the electronic nursing care plan and patient chart with direct access to information. Two ANPs had the idea to create question mark buttons or to provide the information when clicking on nursing interventions or diagnoses of the electronic nursing care plan and patient chart (eg, dressing a wound, assessing the risk of malnutrition, and administering a medication), which was supported by the other ANPs. Links to documents should always point to the latest version, avoiding discrepancies between sources. An additional idea from the interviewed head physician was to link medication prescriptions directly to the electronic nursing care plan and patient chart with instructions for administration. Additionally, powerful search functions and filter options to quickly find relevant information would be helpful for nurses. The goal from the interviewed division manager in nursing care would be a single-source approach where updated instructions were universally accessible. The division maker in nursing care, therefore, said:

> *It must be ensured that the latest version of the nursing instruction is available via the KMS. For example, if you open a link to the nursing instruction from the electronic nursing care plan, the revisions made should also be changed in this document […]. And if something is changed there, I always have the latest version, no matter where I access the document from.* [P7]

Implementation of a KMS

Barriers

Time, money, and personnel constraints were mentioned as the main barriers to the development and implementation of a KMS. The co-nursing manager stressed that the decision-maker of the hospital needs to be convinced of the KMS, as it requires financial investment. The head nurse emphasized that time and financial resources of the hospital must be used sparingly and that the benefits need to outweigh the costs. Additionally, the lack of clarity around responsibilities for integrating KMS content into hospital IT systems was problematic from the head nurses' perspective.

Facilitators

The ANPs saw themselves as responsible for content conceptualization within the KMS. They proposed that IT staff and KMS providers manage the structural and technical implementation. Strong interprofessional collaboration, clear role descriptions, and leadership support were emphasized as important, as an ANP said:

XSL•FO
RenderX

> *The conceptual aspect is for sure with us ANPs. Anything else would be inefficient. But we would not be unhappy if someone else takes care of linking the documents between KMS and the hospital information system.* [P8]

Expected Benefits

Participants believed the KMS would facilitate faster information retrieval, better alignment with current standards, and improved interdisciplinary collaboration. From the head nurse's point of view, this meant that knowledge in nursing could be better preserved and shared. The nurses were convinced that documents were more likely to be used if they were integrated into the nursing process and could be accessed quickly. This could also increase the nurses' sense of safety, as they would always use the correct and updated documents. Moreover, the responsibility for finding the right document would no longer lie with the nurses themselves, as a registered nurse said:

> *And I think it would be of particular benefit to patients, and that is an interprofessional interest. If the nursing staff can stand up afterwards and say, these are our instructions, we have to implement them. The better you know the content of the nursing instructions and the faster you find them, the better you can argue.* [P9]

Potential Quality Indicators

Participants proposed a range of indicators on how to measure the effectiveness of the KMS. The ANPs mentioned direct KMS-related indicators such as time to retrieve information (eg, reduced time to find nursing instructions), task-completion rate (eg, conducting a nursing intervention), need for help in terms of knowledge retrieval (eg, contacting ANP), and user satisfaction with the system. Indirect quality indicators could be downstream outcomes such as quality of care and patient safety. The nurses from the second focus group mentioned the nurses' subjective sense of security when performing nursing interventions as an additional indicator. The head physician and co-nursing manager particularly mentioned the quality of the intra- and interdisciplinary communication, including the perceived ease and frequency of collaboration as further quality indicators. The co-nursing manager said:

> *For me, relevant indicators are the satisfaction and nurses' sense of security in their daily work. The nurses need the information to provide the patient with adequate care.* [P6]

The participants emphasized that an effective KMS should directly support clinical decision-making and increase confidence during care delivery. Nurses frequently linked quick access to correct information with improved performance, lower stress levels, and better patient outcomes. The ANPs and registered nurses believed that evaluating the system's impact should go beyond technical metrics and include experiential factors, such as how secure, informed, and supported they felt while using the system. Furthermore, participants stressed that if a KMS was truly helpful, it would minimize the need for ad hoc knowledge-seeking from team members, reduce errors, and encourage standardized practice across wards. An ANP mentioned:

> *If the information is easy to access whenever they need it, the more they use this information. This, I guess, brings satisfaction because nurses do not have to search a long time for the information and this also indicates a higher sense of security because they know, where they find the information and are well informed.* [P3]

Discussion

Main Results

This study explored nurses' expectations and needs for a KMS integrated into the electronic nursing care plan and patient chart. Participants found the existing hospital information system fragmented and time-consuming. In-house nursing instructions were well-structured but difficult to access due to a confusing filing system and poor search functionality. Nurses often relied on colleagues or ANPs for quick answers, especially under time pressure. Nurses expressed a strong need for a KMS that was integrated into the electronic nursing care plan and patient chart. They envisioned context-sensitive information access, such as clickable links or icons, at each step of the nursing process, from assessment through intervention to evaluation. The system should offer a simplified structure, powerful search functions, and information presented in practical, user-friendly formats like checklists, videos, or brief summaries. To support safe and efficient care, nurses emphasized that information must be both easily retrievable and always up to date. They saw clarity about responsibilities for maintaining the system as essential. Ultimately, they imagined that a well-designed KMS would enhance care quality, streamline workflows, and strengthen nurses' professional confidence at the point of care.

Integrating Knowledge Into Clinical Workflow

Our results show that the current system does not adequately support quick and reliable access to nursing-relevant information at the point of care. Nurses reported relying on team members or navigating complex document systems, often under time pressure. This aligns with findings that emphasize the importance of integrating knowledge tools directly into clinical workflows to reduce search time and cognitive load [4]. Existing help buttons and intranet instructions were appreciated; however, they were not sufficient for efficient knowledge access during daily work. This underscores the importance of embedding knowledge directly into digital workflows. Chorney et al [9] recommended this because they found that integrating KMS into clinical systems significantly improved access and usage. Knowledge embedded in systems not only reduces variation of information and nursing interventions but also supports EBP, given that the content is reliable and up to date [17]. This resonates with the Technology Acceptance Model, which emphasizes perceived usefulness and ease of use as key predictors of usage [18]. The desire for an intuitively designed, workflow-integrated KMS illustrates that these dimensions are central to successful use and implementation.

XSL•FO
RenderX

Information Literacy and the Role of Training

Nurses described variability in their ability to retrieve and apply information, especially among new staff, part-time workers, or those returning from leave. This reflects a broader challenge of information and digital literacy in nursing practice. Training was seen as critical to ensuring consistent access to and use of available knowledge resources. These findings are consistent with earlier studies that show age and experience influence confidence with electronic clinical systems [10] and that tailored onboarding and continued training support more effective system use [17]. Moreover, nurses' literacy influences their attitudes towards and intentions to use KMS [19]. While technical solutions are necessary, they must be accompanied by accessible training formats and support structures to ensure equitable use across roles and experience levels [17].

Evidence Flow and the Role of ANPs

Our study revealed a distinct division of tasks around knowledge sources: while nurses primarily relied on in-house nursing instructions and team members, ANPs engaged with external evidence sources. This distinction reflects the layered process of knowledge use, translation, and transfer outlined by Shahmoradi et al [4]. ANPs acted as translators, adapting external evidence to the hospital's context, while nurses at the point of care used this adapted knowledge. In addition to the application of nursing instructions, information was also transferred via other communication channels such as direct exchange, emails, or newsletters. This confirms findings from Al-Busaidi [20], who emphasized that knowledge transfer in health care often depends on informal systems that are neither systematic nor easily evaluated.

KMS Quality, Functionality, and Usability

A consistent theme in the interviews was the desire for a system that was intuitive, accessible, and available throughout the nursing process. This aligns with previous findings that ease of access and integration into clinical routines are critical success factors for KMS adoption [9]. Participants suggested that its functionalities should include a logical filing system, powerful search capabilities, and support for multiple content formats. This reflects a need for information to be both concise and adaptable to diverse learning preferences [9].

The absence of AI use among participants in the period before and during data collection in 2023 and 2024 also reflects broader hesitations in clinical environments. While AI integration was not expected by participants, its future role in enhancing clinical KMS remains a promising area for development [4]. Regardless of the technology used, the success of the KMS depends on its ability to fit seamlessly into the existing workflow and meet users' needs for quick and trustworthy information [20].

Evaluation and Trust in the System

Participants proposed a range of indicators to evaluate a future KMS, including efficiency gains, time savings, and perceived improvements in quality of care. These are consistent with indicators described by Al-Busaidi [20], who emphasized both organizational and individual-level outcomes such as improved learning, collaboration, and job satisfaction. Nurses in the interviews also framed evaluation in terms of emotional and ethical relief, particularly the idea that linked and validated instructions could reduce their burden of manually searching the "right" document. This does not imply a reduction in professional responsibility but highlights how a well-maintained KMS can support nurses in fulfilling their responsibilities more safely and confidently. This emotional dimension adds a new perspective in understanding trust in digital systems. Trust is shaped not only by technical reliability but also by how systems redistribute responsibility and reduce the risk of error [11]. When knowledge is institutionalized within a centrally maintained KMS, nurses can rely on the organization rather than the individual for ensuring accuracy. This shift reflects a rebalancing of cognitive and ethical responsibility, which can enhance professional confidence and perceived safety in clinical decision-making [21,22].

Organizational Conditions for Success

From the point of view of the head physician, division manager in nursing care, and co-nursing manager interviewed, organizational support emerged as an important factor for KMS success. They highlighted the need for leadership support, funding, and clear roles. These themes are confirmed across multiple studies, which identify infrastructure, staffing, policy support, and leadership engagement as critical to implementation success [1,20]. The findings also align with the Normalization Process Theory, which highlights the processes through which new interventions become embedded in everyday practice [23]. The constructs of shared understanding, cognitive participation, and practical integration are evident in participants' emphasis on collaboration and institutional backing. Organizational culture also plays a key role, as collaborative and open cultures have been found to facilitate KMS adoption more effectively than hierarchical, profit-driven environments [11]. Interviewed ANPs acknowledged the potential value of a KMS, particularly in terms of reducing redundant work and saving time. These findings support the statement from Chorney et al [9], that the success of a KMS is not only a technical or clinical matter, but also a strategic one. For sustainable implementation, the system must align with institutional priorities, demonstrate clear value, and receive long-term support from decision-makers in the setting [20].

Limitations

The main strength of the study was the inclusion of nurses with different levels of work experience and role profiles. This approach allowed for the consideration of multiple perspectives in the implementation of a KMS that was grounded in practical nursing requirements. The interdisciplinary research team balanced clinical and technical expertise but acknowledged that professional backgrounds might have influenced interpretation. Reflexivity was maintained through ongoing discussion to ensure balanced representation of participants' views. Conducting the study in a single hospital allowed for detailed observation of local workflows and knowledge management practices but limits the transferability of findings to other settings with different structures or digital maturity. Another limitation concerns the conceptual nature of the topic, as the study explored expectations for a KMS that has not yet been developed. Finally, the data were collected in German and then

XSL•FO
RenderX

translated into English. These translations were rigorously checked by authors fluent in both languages.

Implications for Nursing Practice and Research

Our findings underscore the importance of designing a KMS that supports nurses' real-time information needs at the point of care. Seamless integration into the electronic nursing care plan and patient chart, intuitive navigation, and access to up-to-date, evidence-based instructions in various formats were seen as essential. Nurse managers should prioritize training, onboarding processes, and continuous support, especially for new, part-time, or returning staff.

There is a need for further research on the design and usability of KMS tools, especially those that leverage emerging technologies such as AI for knowledge synthesis and decision support. Future studies should also explore the implementation and effects of KMS at the point of care. Further investigation into the quality indicators identified by nurses for measuring KMS impact could support the development of validated evaluation frameworks. Future projects from the authors focus on developing and piloting an AI-supported KMS. It aims to provide personalized, evidence-based recommendations tailored to nurses' skill levels and workflows, thereby enhancing safety, quality, and efficiency at the point of care.

Conclusions

Participants expressed a clear need for a KMS that is user-friendly, seamlessly integrated into clinical workflows, and supports quick, reliable access to evidence-based knowledge. A well-designed KMS may have the potential to not only improve care quality and efficiency but also to enhance nurses' confidence and sense of safety in their daily work.

Acknowledgments

The authors thank all the participants who took part in the interviews, focus groups, and observations.

Funding

This study was funded by an Innovationsscheck supported by Innosuisse (INNO-SBM Nr. 66971.1) and by LEP AG, for which we would like to express our thanks. The funder played no role in the study design, data collection, analysis, interpretation, or writing of the report.

Authors' Contributions

Abstract

Background: For clinical nurses, manually entering information into hospital information systems (HISs) remains time-consuming and prone to omissions. Although speech recognition can reduce the need for manual entry, its use in clinical settings has historically been limited by code-switching, medical terminology, and noisy ward environments. Recent advances in customized automatic speech recognition (ASR) and large language models (LLMs) now make speech-based, structured documentation aligned with nursing frameworks such as DART (data, action, response, and teaching) increasingly feasible.

Objective: This study developed and evaluated an integrated ASR and LLM system that transforms spoken nursing input into structured DART notes and evaluated its accuracy, usability, and clinical feasibility within HIS workflows.

Methods: A code-switching nursing speech corpus from emergency and ward settings was used to fine-tune the Whisper large-v2 model with parameter-efficient adaptation. The LLM generated schema-constrained DART records from ASR transcripts, which were verified by nurses before being uploaded to the corresponding HIS fields. Evaluation included mixed error rate for ASR accuracy, F_1-scores, and agreement statistics for DART classification, hallucination assessments based on factual correctness, and analysis of nurse feedback on system use.

Results: The fine-tuned ASR model reduced the mixed error rate from 44.79% to 6.67%. DART generation achieved a macroaveraged F_1-score of 0.82 (95% CI 0.80 - 0.84) and met the noninferiority margin relative to human transcripts (δ=−0.04). The hallucination rate was 2.51%. During deployment, the monthly volume of valid nursing notes generated through voluntary use of the ASR system increased from 32,724 to 65,417, where each note represented a single documentation entry generated per patient care episode. Among 120 participating nurses, 91 (75.8%) reported reduced workload and improved completeness.

Conclusions: The integrated ASR and LLM system was feasible and showed strong performance, with good acceptance among clinical nurses. It reduced the manual documentation burden, improved record completeness, and demonstrated the value of an ASR- and LLM-supported workflow for nursing documentation.

Introduction

Taiwan has faced a sustained shortage of clinical nurses, driven largely by low retention among licensed professionals rather than limited training capacity. The national nursing practice rate—representing the percentage of licensed nurses actively working in the profession—remains at only 59.1% [1]. This low retention of qualified staff exacerbates the clinical shortage, and excessive workloads and long shifts are strongly associated with burnout and turnover intention [2-4]. Documentation occupies a substantial portion of clinical workflow time, and existing digital systems have not fully reduced the need for manual input. As hospitals have expanded the use of hospital information systems (HISs), additional documentation requirements have emerged, prompting efforts to standardize formats and improve system integration [5]. Structured and interoperable records support continuity of care, and structured handoff protocols improve communication quality [6,7].

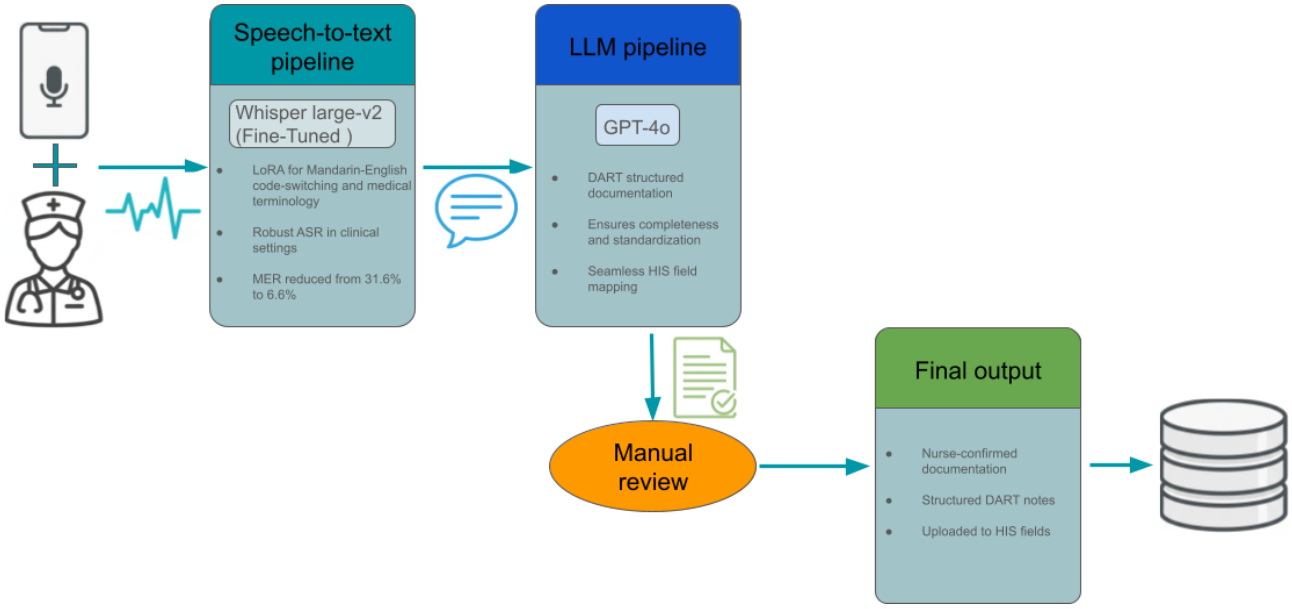
XSL•FO
RenderX

Moreover, higher perceived nursing information system quality is linked to greater use, satisfaction, and retention, while electronic record use embedded in routine workflows reduces documentation workload and intention to leave [8,9]. These findings highlight the need for documentation tools that are structured, interoperable, and well-integrated into daily clinical practice.

Many hospitals have introduced structured documentation frameworks to improve consistency and communication. Among these, the Focus Charting method has been particularly influential in Taiwan. Originating in the late 1980s [10] and adopted locally in the early 1990s [11], it organizes each nursing note around a defined patient focus and follows the DART (data, action, response, and teaching) pattern to support concise and standardized recording of observations, interventions, patient responses, and teaching activities. Implementation studies have reported clearer note organization, improved execution of care plans, and enhanced interdisciplinary collaboration in intensive care settings [12]. However, structured formats alone do not resolve the documentation burden. Even with electronic templates, nurses must still enter most information manually, and flowsheets—standardized tabular records used for tracking routine, time-sequenced clinical parameters such as vital signs—may occupy a substantial portion of each shift [13]. These limitations highlight the need for intelligent support that preserves the clarity of DART records while reducing repetitive manual effort.

Automatic speech recognition (ASR) has been explored as a way to reduce manual documentation effort, with multisite evaluations reporting higher efficiency and satisfaction [14,15]. In Taiwan, a longitudinal study involving 21 nurses (using a corpus of 30,112 words) found that mean accuracy improved from 87.06% to 95.07% across 4 evaluation sessions as users developed more stable speaking speeds and volumes [16]. Furthermore, an ASR system designed for code-switching—the practice of alternating between languages, such as Mandarin and English, within a single utterance—achieved a word error rate (a standard metric representing the percentage of transcription errors) of 12.3% in intensive care settings [17].

Recent reviews suggest that clinical speech technologies are rapidly evolving toward large language model (LLM)–driven ambient clinical intelligence, with mature commercial solutions (such as Heidi, Tortus, and Rebrief.ai [Rebrief Inc]) being successfully deployed in various settings to provide summarization, repurposing, and assistive autonomy [18]. However, although these ambient scribes excel in standard clinical encounters, their direct application to Taiwanese nursing workflows presents significant challenges. First, commercial systems are primarily optimized for monolingual or standard bilingual speech and often struggle with the dense, specialized Mandarin-English code-switching and local abbreviations prevalent in Taiwanese hospital wards. Second, existing tools typically generate generalized clinical summaries (eg, subjective, objective, assessment, and plan notes), lacking the fine-grained, schema-constrained precision required for specialized nursing frameworks such as DART and its direct interoperability with local HISs. Therefore, a bespoke ASR and LLM pipeline is necessary to address these specific linguistic and structural demands. To bridge this gap, this study developed and evaluated an integrated voice-to-report system that combines a domain-adapted ASR model with an LLM to generate structured DART nursing documentation aligned with HIS fields. The system was assessed using transcription accuracy, DART classification performance, and noninferiority testing, and its feasibility and workflow impact were examined during real-world deployment.



Methods

Study Design and System Overview

This development and evaluation study implemented a mobile-based nursing documentation system designed to convert voice input into structured clinical records (Figure 1). The system was deployed at China Medical University Hospital (CMUH) to evaluate its feasibility, transcription accuracy, and impact on documentation workflow. During routine care, nurses recorded observations and interventions using a mobile device. Audio input was processed by a domain-adapted Whisper ASR model trained on a Mandarin-English code-switching corpus and adapted to the medical terminology common in nursing communication. Transcribed text was subsequently processed by GPT-4o (OpenAI) using a schema-constrained prompt to generate standardized DART notes primarily in Mandarin while preserving English medical terminology. Nurses reviewed the generated content and triggered its upload to predefined HIS fields.

RenderX

Figure 1. Workflow of the voice-to-DART (data, action, response, and teaching) documentation system. ASR: automatic speech recognition; HIS: hospital information system; LLM: large language model; LoRA: low-rank adaptation; MER: mixed error rate.

The system was developed in-house by the Artificial Intelligence and Robotics Innovation Center at CMUH. The codebase and intellectual property are proprietary. Due to strict patient privacy regulations and direct HIS integration, the software and raw datasets are not publicly available. However, to ensure methodological reproducibility, all model hyperparameters, evaluation frameworks, and complete schema-constrained prompt templates are fully detailed in this paper and Multimedia Appendix 1.

Dataset and Ground-Truth Preparation

The ASR model was trained and evaluated on nursing speech data from 3 complementary sources. The primary corpus, CMaiSpeech, comprised spontaneous Mandarin-English code-switched recordings from 525 nurses across multiple clinical units, characterized by frequent English medical terms and abbreviations. Table 1 summarizes the counts and durations of CMaiSpeech by category. Two synthetic corpora (approximately 9 hours) were generated using neural text-to-speech models from 1838 drug names and 1566 clinical terms to enrich underrepresented medical vocabulary. A real-world clinical dataset (totaling approximately 6 hours, 1608 utterances) captured authentic ward conversations, including vital-sign reporting and handovers. All recordings were normalized and resampled to 16-kHz pulse code modulation to ensure acoustic consistency. These datasets collectively served as the domain-adapted speech material used for training and evaluating the Whisper-based ASR model in nursing contexts.

In addition, a validation dataset of 327 nurse-authored documentation samples was constructed. Each sample included an audio recording collected during routine care, a manually transcribed reference serving as the ASR gold standard, and structured DART annotations verified by clinical nurses. This dataset was used to evaluate ASR transcription accuracy, LLM-based DART structuring, and agreement between fine-tuned and zero-shot conditions under a consistent reference standard.

Table . Counts and audio durations by category in the CMaiSpeech dataset.

Category	Item count (N=7055), n (%)	Audio length (seconds)[a]
Diastolic BP[b]	20 (0.28)	36.57
Glasgow Coma Scale eye response component	20 (0.28)	99.61
Pain index	20 (0.28)	46.05
Pulse	20 (0.28)	34.27
Systolic BP	20 (0.28)	39.34
Body temperature	20 (0.28)	39.10
Vital signs[c]	1035 (14.67)	12,350.10
Nursing notes[c]	5900 (83.65)	75,149.10

[a]Total duration of all audio samples within each category.

[b]BP: blood pressure.

[c]Categories representing full-length clinical recordings captured during routine nursing documentation activities.

ASR Model Adaptation and Evaluation

Whisper is a multilingual Transformer-based ASR model pretrained on 680,000 hours of diverse speech data [19]. Although its large-scale pretraining supports robust zero-shot generalization, accuracy declines in nursing-specific communication, where frequent Mandarin-English code-switching, dense medical terminology, and numerous drug abbreviations remain underrepresented. These discrepancies limit its direct applicability to structured nursing documentation.

Prior studies have demonstrated that domain-targeted fine-tuning markedly improves Whisper's performance in medical and mixed-language contexts. Previous studies reported gains in ASR and named entity recognition on Mandarin speech [20], and further improvements were achieved using domain-adapted fine-tuning and prompting on Mandarin-English medical data [21]. Building on these findings, Whisper (large-v2; OpenAI) was adapted to the nursing domain through low-rank adaptation–based parameter-efficient fine-tuning, which introduced trainable low-rank matrices into frozen weights to reduce computational cost while preserving performance [22]. The model was trained on a domain-specific nursing speech corpus and evaluated using mixed error rate (MER) to assess bilingual transcription accuracy relative to the baseline model.

Prior to MER calculation, a rigorous text normalization pipeline was applied to both reference and hypothesis transcripts to ensure consistent scoring. All full-width alphanumeric characters were converted to half-width equivalents, and punctuation marks were removed. Original casing for English text and medical abbreviations (eg, "SpO_2" and "BP") was strictly preserved to evaluate the model's ability to output correctly capitalized clinical terms. Crucially, numeric values, including decimals, were evaluated as independent, contiguous tokens rather than as split characters to accurately reflect their semantic weight in clinical parameters such as vital signs.

LLM Integration and Evaluation

The LLM was integrated to convert ASR transcripts into structured nursing documentation following the DART schema. GPT-4o (accessed via Azure OpenAI, application programming interface version 2024-12-01-preview), a multimodal variant of the GPT-4o family optimized for instruction following and multilingual text generation, was used for schema-based text structuring [23]. The model hyperparameters were consistently set to a temperature of 0.7, a top_p of 0.95, and a maximum of 16,000 tokens. A schema-constrained prompting strategy was applied to ensure consistent field separation and syntactic completeness, informed by prior evidence that structured prompting improves validity in clinical text generation [24]. The generation process used a dual-prompt structure: a system prompt defining the explicit task instructions and schema constraints, and a user prompt containing the ASR transcript. Two prompting configurations (a minimal version and a schema-constrained version) were compared during preliminary testing, and the schema-constrained configuration was selected for deployment. The full system prompt template is provided in Multimedia Appendix 1.

Model outputs were postprocessed to verify structural integrity and mapped to predefined HIS fields. LLM performance was evaluated on the 327-case validation dataset using field-level and macroaveraged F_1-score values across DART categories. The 95% CIs were estimated using 1000 paired bootstrap resamples at the case level. Noninferiority was tested using a predefined margin of δ=0.05, with noninferiority established when the lower bound of the ΔF_1-score CI exceeded −0.05. This 5% margin aligns with recent clinical evaluations of LLM-generated medical documentation, where a <5% variance is considered clinically acceptable for draft generation [25], and serves as a standard threshold in medical artificial intelligence performance evaluations [26]. From a clinical safety perspective, because the system captures data directly at the bedside via mobile devices, it inherently mitigates the high, undocumented risk of human memory decay and omission associated with traditional delayed documentation at the nursing station. Furthermore, because the system strictly requires human-in-the-loop verification prior to HIS submission, this minor structural variance during the drafting stage was deemed an acceptable trade-off for reduced documentation burden, while human oversight securely mitigates the risk of high-severity clinical errors.

Agreement Method

Three input conditions were compared while holding the structuring LLM constant: (1) human transcripts (reference), (2) Whisper large-v2 (zero-shot), and (3) Whisper large-v2 (fine-tuned). The primary end point was the F_1-score for DART slot classification against adjudicated references. A predefined noninferiority margin of δ=0.05 for ΔF_1-score was applied, and 95% CIs were estimated using paired bootstrap resampling. Noninferiority was established when the lower bound of the ΔF_1-score CI exceeded −0.05.

Field-level consistency was assessed because the "data," "action," "response," and "teaching" components of the DART framework represent distinct documentation intents. Labels were binarized (present-or-absent) after whitespace trimming, and both percent agreement and Cohen κ were calculated to adjust for chance agreement under skewed prevalence distributions [27].

It should be noted that the binarized F_1-score and agreement metrics were specifically chosen to evaluate the system's capability in initial structural triaging, ensuring that the LLM correctly maps spoken intents to the corresponding DART fields. Because the system operates within a strict human-in-the-loop workflow in which nurses must review and adjust the drafted text prior to HIS submission, achieving high structural accuracy significantly reduces manual documentation burden, even if minor within-field reallocations are occasionally required. To address content accuracy and penalize clinically incorrect information within these fields, the FactualCorrectness metric was used separately during the hallucination assessment.

Hallucination Assessment

Hallucination was defined as any generated content that lacked support from the corresponding reference transcript for the same case. Evaluation followed the FactualCorrectness metric from

XSL•FO
RenderX

the Retrieval-Augmented Generation Assessment (RAGAS) framework (precision mode), which decomposes model output into atomic claims and verifies each claim against the reference transcript [28,29]. A fixed Azure OpenAI model (GPT-4o, application programming interface version 2024-12-01-preview; temperature=0.7, top_p=0.95) was used as the evaluator via a LangChain wrapper to ensure consistent claim-level scoring. For each case, the 4 DART fields were concatenated into a single response, and both generated and reference texts were normalized prior to evaluation.

Mean factual-correctness precision and its complement (hallucination rate) were reported, along with the proportion of notes exhibiting hallucination under strict (<1.00) and relaxed (<0.95) thresholds. All computations were performed in Python (version 3.12; Python Software Foundation) using the RAGAS library [30].

System Use and User Feedback

To evaluate real-world feasibility and system adoption, use metrics were monitored during the initial deployment period at CMUH. Monthly use was quantified by extracting the total number of system-generated records from the application logs between March 2025 and August 2025.

Additionally, user feedback was collected to assess system acceptability and its impact on clinical workflow. Nursing staff from diverse clinical units, including wards and intensive care departments, voluntarily provided evaluations after integrating the system into their routine practice. The evaluation mechanism captured both quantitative satisfaction ratings (categorized as favorable or dissatisfied) and qualitative comments regarding user experience. Descriptive statistics were used to summarize the quantitative use and satisfaction data, while qualitative feedback underwent thematic analysis to identify common themes related to documentation efficiency, manual workload, and system accuracy.

Ethical Considerations

This study was approved by the Institutional Review Board of CMUH (CMUH110-REC2-181 and CMUH110-REC2-187). Since this was a retrospective study utilizing deidentified data, the requirement for informed consent was waived by the institutional review board. Patient privacy and data confidentiality were strictly maintained throughout the study, and no compensation was involved.

Results

Evaluation Dataset Characteristics

The evaluation dataset comprised 327 annotated nursing documentation samples, as described in the Methods section. Across transcripts, the corpus contained 12,136 Chinese characters, 1361 English words, and 1130 numeric tokens, equivalent to approximately 11.2 English words per 100 Chinese characters (Table 2, panel A). A total of 540 DART annotations were identified: 257 (47.6%) for “data,” 123 (22.8%) for “action,” 123 (22.8%) for “response,” and 37 (6.9%) for “teaching” (Table 2, panel B). The lower frequency of “teaching” entries reflects routine documentation patterns and was accounted for when estimating field-specific CIs. This dataset served as the common benchmark for evaluating both ASR and LLM outputs.

Table . Token composition and DART (data, action, response, and teaching) annotation distribution in the evaluation dataset.

Panels and categories	Distribution, n (%)	Count per sample[b], mean (SD)
Panel A: token[a] composition (n=14,627)		
Chinese characters	12,136 (83.0)	37.11 (24.31)
English words	1361 (9.3)	4.16 (5.56)
Numeric tokens	1130 (7.7)	3.46 (4.97)
Panel B: DART annotation distribution (n=540)		
Data	257 (47.6)	0.79 (0.41)
Action	123 (22.8)	0.38 (0.49)
Response	123 (22.8)	0.38 (0.49)
Teaching	37 (6.8)	0.11 (0.32)

[a]Token counts were computed from manual transcripts after text normalization; Chinese tokens represent individual characters, English tokens represent space-delimited words, and numeric tokens represent digit sequences.

[b]Values were calculated by dividing counts by the total number of samples (n=327).

ASR Model Performance

Whisper large-v2 was evaluated using MER, computed at the character level for Chinese and at the word level for English. In the zero-shot condition, MER was 44.79%. After low-rank adaptation–based fine-tuning on the nursing corpus, MER decreased to 6.67%, corresponding to an 85.11% relative error reduction (Table 3).

XSL•FO
RenderX

Table . Performance of Whisper large-v2 on the evaluation dataset.

Models	Mixed error rate (%)	Relative error reduction (%)
Zero-shot model[a]	44.79	—[b]
Fine-tuned model[c]	6.67	85.11

[a]Zero-shot: Whisper-Large-v2 inference without domain adaptation.

[b]Not applicable.

[c]Fine-tuned: Whisper-Large-v2 adapted using low-rank adaptation LoRA on the nursing speech corpus.

DART Classification Performance

DART classification performance was evaluated under 3 input conditions: human-transcribed references, fine-tuned ASR, and zero-shot ASR (Table 4). A schema-constrained prompting strategy was used for all analyses after preliminary comparison showed higher slot-level completeness and F_1-score performance than a minimal prompt.

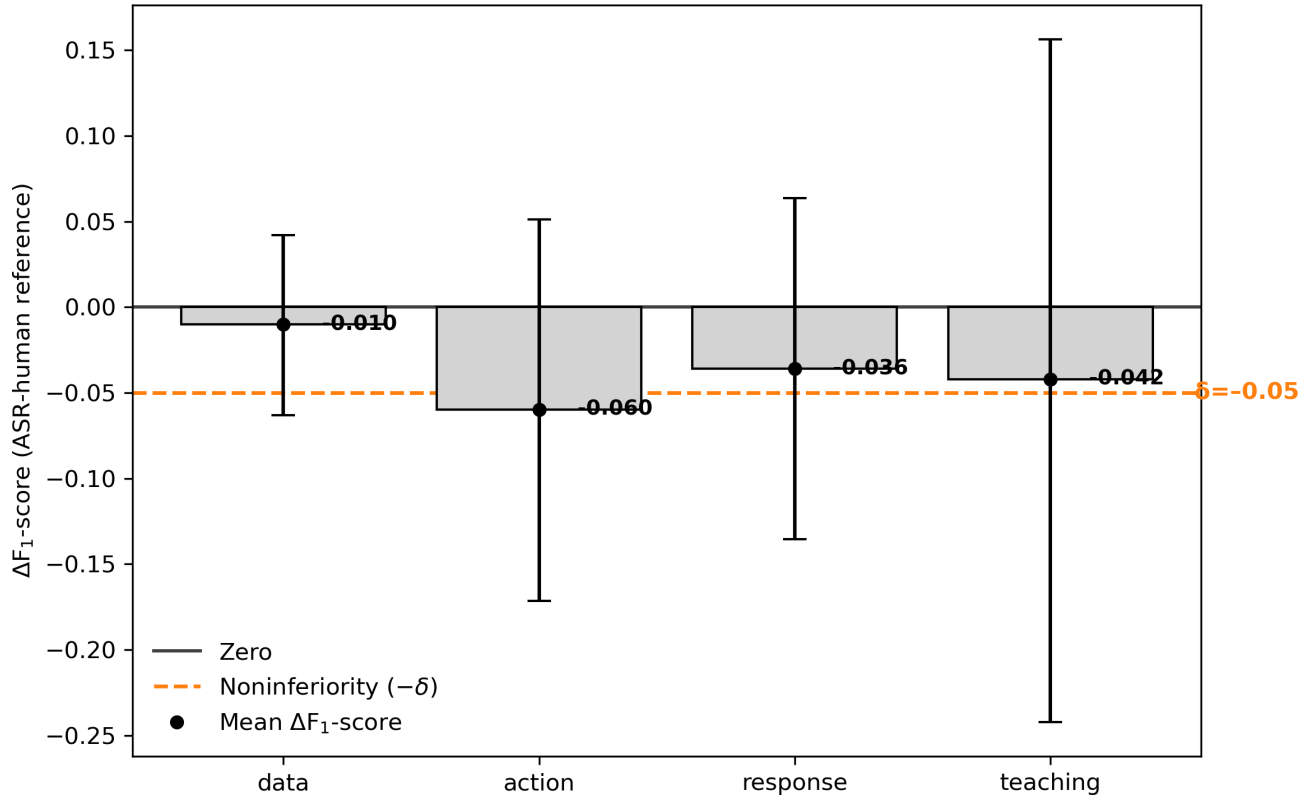
Table . Per-field DART (data, action, response, and teaching) F_1-score performance with 95% CIs under 3 input conditions.

Fields	Zero-shot[a], F_1-score (95% CI)	Fine-tuned[b], F_1-score (95% CI)	Human transcript[c], F_1-score (95% CI)
Data	0.89 (0.85 - 0.92)	0.90 (0.87 - 0.93)	0.91 (0.89 - 0.94)
Action	0.59 (0.53 - 0.66)	0.77 (0.73 - 0.81)	0.83 (0.79 - 0.86)
Response	0.72 (0.67 - 0.77)	0.82 (0.79 - 0.85)	0.85 (0.82 - 0.88)
Teaching	0.62 (0.56 - 0.68)	0.78 (0.73 - 0.82)	0.83 (0.79 - 0.86)
Macroaverage[d]	0.70 (0.68 - 0.72)	0.82 (0.80 - 0.84)	0.85 (0.83 - 0.87)

[a]Zero-shot inference without domain adaptation.

[b]Fine-tuned using low-rank adaptation on the nursing speech corpus.

[c]Manually transcribed references used as the gold standard for automatic speech recognition evaluation.



[d]Unweighted mean F_1-score across data, action, response, and teaching fields.

With this configuration, overall F_1-score values were 0.85 for human transcripts, 0.82 for fine-tuned ASR, and 0.70 for zero-shot ASR. The difference between fine-tuned ASR and human input (ΔF_1-score=−0.03) fell within the predefined noninferiority margin (δ=0.05). Field-level ΔF_1-score values ranged from −0.01 (for “data”) to −0.06 (for “action”). Zero-shot ASR showed uniformly lower performance across all fields.

Figure 2 presents field-level ΔF_1-score estimates with 95% CIs. All field means remained within the noninferiority boundary, supporting noninferiority at the macro level.

XSL•FO
RenderX

Figure 2. Field-level ΔF_1-score values (automatic speech recognition [ASR]–human reference) with 95% CIs and the noninferiority boundary (δ=−0.05).

Agreement Evaluation

Concordance was assessed across the 3 input conditions while holding the LLM constant. Agreement between classifications derived from the fine-tuned ASR and human transcripts ranged from 88.38% to 96.94%, with Cohen κ ranging from 0.66 to 0.86 across the "data," "action," "response," and "teaching" fields (Table 5), corresponding to substantial to almost perfect agreement [28]. For the "data" field, raw agreement was 95.41% with κ=0.66, a pattern consistent with imbalanced class prevalence. Overall, slot-level results were consistent with the macrolevel noninferiority findings.

Table . Agreement and Cohen kappa for DART (data, action, response, and teaching) fields comparing large language model outputs generated from fine-tuned automatic speech recognition with outputs from human transcripts.

Fields	Agreement[a] (%)	Cohen κ[b]
Data	95.41	0.66
Action	88.38	0.75
Response	89.91	0.79
Teaching	96.94	0.86

[a]Percent agreement between large language model outputs generated from fine-tuned automatic speech recognition transcripts and human transcript inputs.

[b]Chance-corrected agreement coefficient computed using the standard Cohen kappa formulation.

Hallucination Evaluation

Hallucination rates were evaluated using the FactualCorrectness metric from the RAGAS framework in precision mode (Table 6). With human transcripts, the mean hallucination rate was 2.35% (SD 9.93%; 95% CI 1.27–3.43), and hallucinations were detected in 28 (8.56%) samples (95% CI 5.99–12.10). Fine-tuned ASR yielded a mean hallucination rate of 2.51% (SD 10.86%; 95% CI 1.33–3.70), with hallucinations detected in 26 (7.95%) samples (95% CI 5.48–11.40). Zero-shot ASR showed higher hallucination rates, with a mean rate of 8.98% (SD 23.99%; 95% CI 6.36–11.60) and hallucinations detected in 65 (20%) samples (95% CI 16.01–24.69).

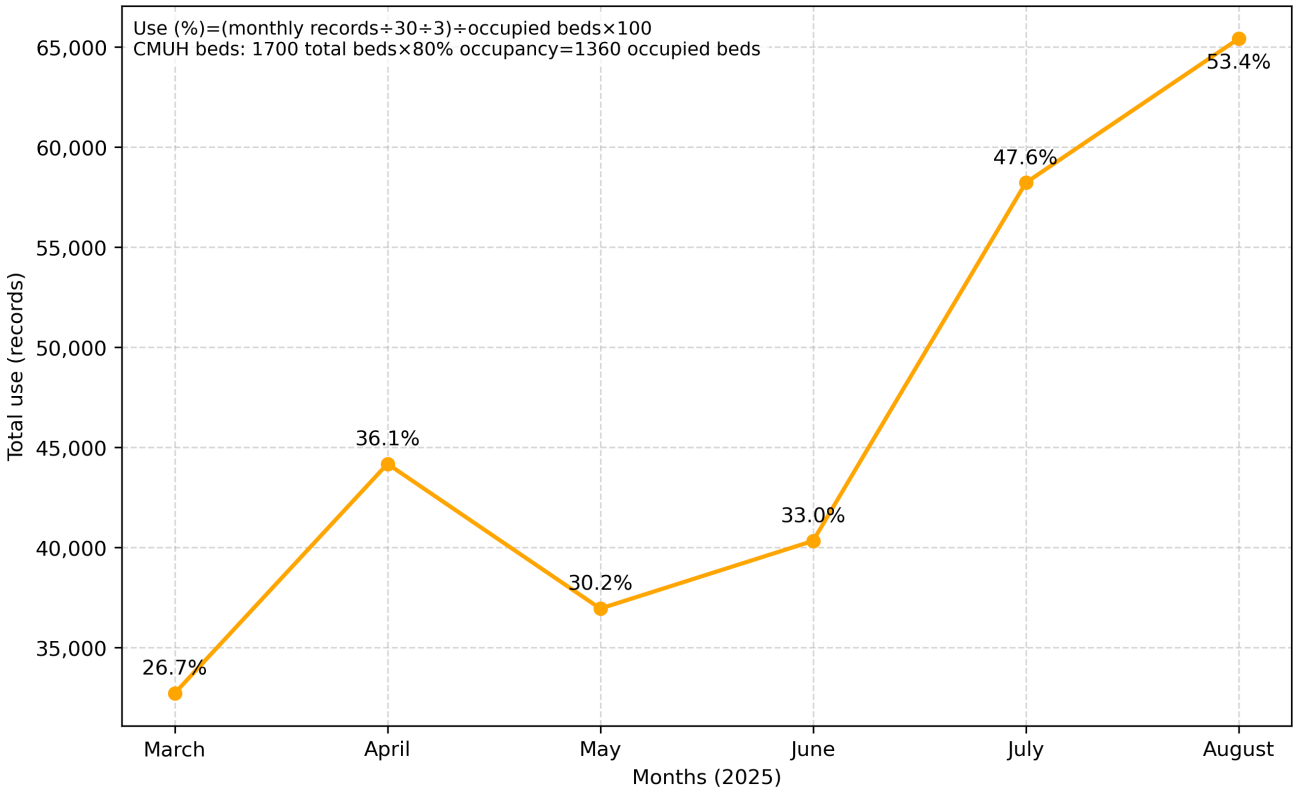
XSL•FO
RenderX

Table . Hallucination rates of large language model outputs across different input sources.

Input sources	Hallucination rate[a] (%), mean (SD)	Samples with hallucination[b], n (%)
Human transcript	2.35 (9.93)	28 (8.56)
Fine-tuned ASR[c]	2.51 (10.86)	26 (7.95)
Zero-shot ASR	8.98 (23.99)	65 (20.00)

[a]Computed using the FactualCorrectness metric (precision mode), representing the proportion of hallucinated tokens relative to all generated tokens.

[b]Percentage of evaluation samples containing at least 1 hallucination (n=327).



[c]ASR: automatic speech recognition.

System Use and User Feedback

Following deployment, the system was increasingly incorporated into routine documentation at CMUH. Monthly use nearly doubled between March 2025 and August 2025, rising from 32,724 to 65,417 valid DART notes generated and uploaded to the HIS through voluntary use of the system (Figure 3). This upward steady increase indicates expanded use across clinical units during the initial deployment period.

User feedback was collected from a subset of nursing staff who voluntarily provided evaluations (n=120, representing approximately 12.2% of the 982 nurses actively working in the 44 participating units across wards and intensive care departments). Among these participants, 91 (75.8%) nurses reported a favorable experience, whereas 29 (24.2%) expressed dissatisfaction. Positive feedback emphasized reductions in manual transcription burden and improvements in documentation efficiency, whereas negative feedback primarily concerned occasional recognition inaccuracies and the continued need for verification. Although the feedback sample does not represent all users, it reflects the perspectives of frontline staff actively engaged with the system. Detailed departmental participation is provided in Multimedia Appendix 2. Collectively, these findings demonstrate that the system is both technically feasible and operationally acceptable in real-world clinical environments.

Figure 3. Monthly system use at China Medical University Hospital (CMUH) from March 2025 to August 2025.

Discussion

This study designed and implemented a speech-based documentation system that integrates a domain-adapted ASR model with an LLM to generate structured nursing records and evaluated its performance in real clinical settings. The fine-tuned Whisper large-v2 model achieved a MER of 6.6%, demonstrating high accuracy for Mandarin-English nursing speech. With schema-guided LLM structuring, the system reached an F_1-score of 0.82, which was statistically noninferior to human-transcribed input, and exhibited a low hallucination frequency (2.51%). These findings indicate that domain-adapted ASR combined with LLM-based structuring can produce structurally consistent draft documentation that, alongside

XSL•FO
RenderX

routine human verification, reduces cognitive and transcription burden in routine practice.

Field deployment demonstrated that the system could be incorporated into routine clinical workflows. By enabling point-of-care mobile dictation directly at the bedside, the system effectively replaced the traditional, error-prone workflow of delayed, memory-reliant documentation at the nursing station, directly addressing the critical pain points exacerbated by high nurse-to-patient ratios. System use doubled over the 6-month observation period. Because the hospital operates at a consistently high and stable capacity, this increase in absolute volume was not driven by fluctuations in patient census. Rather, as the system was deployed as an optional tool, this steady growth reflects successful voluntary adoption, supported by continuous iterative optimizations based on user feedback. Feedback from nursing staff further supported its usability. Most respondents reported reduced manual effort and improved efficiency, while negative feedback focused on recognition accuracy and the need for verification, which aligns with the human-in-the-loop design. Participation across 6 major ward categories indicates that the system was used in a wide range of clinical settings.

Several limitations warrant consideration. First, the dataset was modest and sourced from a single institution, which may constrain generalizability. Second, user feedback was voluntary and may overrepresent individuals who were more engaged with the system, and long-term patterns of use were not assessed. Third, our evaluation of structural content accuracy and hallucination relied primarily on an LLM-as-a-judge framework (RAGAS). The primary purpose of this evaluation was to conduct a strict semantic fidelity check, ensuring that the LLM strictly formatted the ASR transcripts into the DART schema without altering, inferring, or omitting clinical facts. Although RAGAS performs robust semantic contradiction checks, traditional non-LLM baselines (eg, exact string matching) were deemed unsuitable because of the heavy code-switching and spoken-to-written paraphrasing inherent in nursing documentation. Although senior nursing staff qualitatively reviewed the generated drafts within our human-in-the-loop workflow, the lack of a formal, quantitative manual fidelity evaluation on a stratified sample of high-risk note types by nursing professionals remains a limitation. Future work should include multisite validation; evaluation of interoperability with diverse HIS environments; dedicated quantitative manual safety reviews by senior nurses to further validate that the LLM does not alter critical nursing parameters (eg, medication dosages and invasive device settings); and longitudinal assessment of impacts on documentation quality, workflow efficiency, and staff satisfaction.

Abstract

Background: Clinical decision support (CDS) tools embedded in electronic health records in the form of integrated clinical prediction rules provide a potentially effective intervention to reduce inappropriate antibiotic prescribing for acute respiratory infections. However, their effectiveness has been limited by workflow barriers and low adoption by health care providers. Nurses are well positioned to implement evidence-based protocols using CDS tools. In a multicenter randomized controlled trial, a nurse-led implementation strategy for acute respiratory infection integrated clinical prediction rules was evaluated for use in primary care and urgent care settings.

Objective: This study aimed to examine nurse and nurse leader perspectives on the sustainability of an electronic health record–integrated CDS tool for antibiotic stewardship and explored factors influencing its potential long-term integration into ambulatory nursing practice beyond the clinical trial.

Methods: We interviewed 22 nurses and nurse leaders from 37 clinics across 3 academic medical centers that participated in the clinical trial. Two semistructured interview guides, one for nurses and one for nursing leadership, were developed to understand the barriers and facilitators to implementing a decision aid tool for nurses and to elicit challenges specific to nursing interactions with the CDS tool. Interviews were recorded and transcribed. Using thematic content analysis and iterative coding, our team collaboratively identified emerging themes related to sustainability and refined the results with consensus.

Results: Five themes emerged: (1) importance of staffing stability and capacity, (2) impact of dedicated clinic resource availability, (3) variable nurse readiness with CDS-guided clinical care, (4) influence of openness to change and a nurse-supportive clinic culture, and (5) ongoing need for training and support. Specific recommendations for future actions were also noted.

Conclusions: Our findings revealed specific barriers and facilitators to the sustainability of a CDS tool from the nursing perspective that can inform further implementation of nurse-led delegation protocols in the ambulatory setting. Future solutions should consider mapping physical workflows, scheduling specific to nurse visits, continuing education, and treating cough and sore throat as 2 distinct processes.

KEYWORDS

clinical decision support systems; electronic health records; nursing; antibiotic stewardship; ambulatory care facilities

Introduction

Antibiotic resistance is a growing global health concern, exacerbated by the overprescription of antibiotics for acute respiratory infections (ARIs) [1]. Despite available evidence-based guidelines and clinical decision support (CDS), physicians often prescribe antibiotics inappropriately due to perceived patient expectations, time pressures, and cognitive fatigue [2]. To address this issue, clinical prediction rule (CPR) systems have been developed and integrated as integrated clinical prediction rules (iCPRs) into electronic health records (EHRs) as CDS to assist physicians in making informed antibiotic prescribing decisions [3,4]. However, their impact has been limited by low provider adoption rates [5,6]. Evidence

XSL•FO
RenderX

suggests that registered nurses (RNs) have the potential to implement evidence-based protocols [7,8], participate in antimicrobial stewardship [9], achieve high patient satisfaction and symptom resolution [7], and demonstrate higher adoption rates of CDS tools than physician-led initiatives [10].

Building on this potential, the multicenter, step-wedge, cluster randomized controlled trial (iCPR3 RCT) evaluated whether RNs could effectively use iCPR tools to guide evidence-based care for patients presenting with ARIs in ambulatory care settings [11,12].

An early implementation assessment identified several potential barriers and facilitators to adopting the nurse-driven CDS tools [10]. As the iCPR3 RCT concluded, we sought to understand whether nursing departments would consider continuing to use iCPR tools in clinical practice after research support was withdrawn. We also aimed to identify barriers that may hinder sustained use within ARI workflows beyond the study period. By examining these perspectives, our goal was to identify strategies to sustain nurse-led use of iCPR tools in clinical practice as a means to improve patient outcomes [13].

Methods

Research Design

We used semistructured interviews and thematic analysis to examine the perspectives of RNs and nurse leaders regarding the sustainability of the iCPR tools, including aspects of implementation, usability, and perceived impact. For the purposes of this study, we defined sustainability as the extent to which nurses would continue to use a tool as part of standard clinical workflows beyond the study period and without research personnel implementation support or incentives.

Ethical Considerations

The study protocol and procedures were approved by the NYU Langone Health Institutional Review Board (NYULH study number i19-01222), which served as the study's single institutional review board. We received a waiver of written informed consent for this study. All study data reported in this manuscript are deidentified. Compensation was provided in accordance with institutional policies.

Nurse iCPR Intervention

The nurse intervention used a structured delegation protocol, wherein the specific clinical task of assessing the need for antibiotics in low-acuity ARI patients was transferred from a physician to an RN. Provider-to-nurse delegation is operationalized through protocol-driven authorization of nursing tasks by a licensed provider, with accountability retained by the delegating provider. In the iCPR3 RCT, the intervention consisted of triage followed by in-person CDS-guided RN visits for patients with low-acuity ARI symptoms. The EHR-integrated CDS included a triage note template to assess symptoms and acuity and 2 reason-for-visit-specific (ie, sore throat or cough) note templates with iCPRs that guide RNs to complete an evidence-based risk calculator as part of the visit [12]. The resulting risk score is linked to an order set for diagnostic testing, prescriptions, and patient instructions.

All tasks performed by RNs as part of the intervention—triage, symptom assessment, use of CDS tools, and execution of evidence-based care pathways—are well within the scope of nursing practice and align with their clinical training. The iCPRs used were previously found to be effective for reducing inappropriate antibiotic prescribing when used by physicians [2,4,11]. The intervention aimed to standardize care delivery and reduce unnecessary antibiotic use in outpatient settings.

The intervention was implemented as a pragmatic stepped-wedge cluster randomized trial across 43 primary and urgent care practices in 3 academic health systems affiliated with the University of Utah, the University of Wisconsin, and NYU Langone. To be eligible for participation, practices were required to have at least 1 RN full-time equivalent capable of performing triage within the EHR and conducting RN on-site visits. Nurses in the intervention group received 1 hour of online training prior to 1 hour of in-person training on how to use the iCPR tool, including background on the iCPRs, EHR-based walkthroughs of using the iCPR tool within the CDS, demonstration videos simulating the tool in a live clinical encounter, and clinical training for physical examinations [11]. Complete study procedures are reported elsewhere [12].

Study Design

We conducted remote video interviews (via Zoom and Webex) lasting approximately 30 minutes between September 2024 and January 2025. Each participant was interviewed by a trained research team member from the corresponding health system (NH, KM, AY, VT) using 1 of 2 semistructured interview guides. Our team developed these interview guides, 1 for RNs and 1 for leadership, based on a series of open-ended structured questions previously used in a validated survey to understand the barriers and facilitators to implementing a lupus decision aid tool for nurses [14]. We adapted the questions to explore relevant Consolidated Framework for Implementation Research (CFIR) constructs, as well as address conditions specific to the ambulatory care environment and the iCPR intervention; we retained all other aspects of the survey [15]. Interviews consisted of questions to understand barriers and facilitators related to tool use, clinical team interactions, what worked well, any competing priorities, strategies for mitigating issues, and future adoption sustainability (see Tables S1 and S2 in Multimedia Appendix 1). Probing questions were used to verify the interpretation of participant responses, and recommendations were solicited for continued use of the iCPR tool in clinical workflows.

Participants

We recruited a convenience sample of RNs and nurse leaders (did not have to be an RN) from primary care clinics and urgent care centers participating in iCPR3. Participants were considered eligible if they expressed familiarity with the iCPR tool and, if they were nurse participants, had completed a nurse visit using the tool. Participants were recruited via email by study personnel at each site. Recruitment procedures varied slightly by study site due to local policies and conditions. Specifically, given the proportionately large number of clinics at the University of Wisconsin (21 clinics vs 9 and 7 clinics at NYU and Utah, respectively) and with the objective of obtaining diverse

XSL•FO
RenderX

perspectives, participants were recruited as a stratified convenience sample from the top and bottom 5 performing clinics, based on the average number of nurse visits completed per week per clinic volume at randomization. In addition, University of Utah participants were offered a US $25 gift card as an incentive, whereas other study sites did not provide financial incentives due to institutional policies around employee compensation. A member of the study team verbally reviewed the study information with each participant to ensure understanding; all participants then provided verbal agreement to participate.

Thematic Analysis Procedures

We conducted a thematic content analysis to identify themes related to sustainability by extracting high-level themes from the data while examining the frequency of concepts or keywords [16]. Each interview was audio-recorded and transcribed using an automated service (Landmark Associates). One team member (NH) reviewed each file for transcription accuracy prior to analysis. Transcripts were analyzed, and a codebook was developed using Dedoose [17].

We first conducted a joint analysis of 2 interviews to allow the study team members to become accustomed to the codebook, make updates to codes, and resolve conflicts. All study team members were trained in qualitative techniques. Next, 2 team members coded each transcript independently, and then all coders (VT, NG, MB, KM, AT) met as a team to compare and resolve disagreements. During this process, we reviewed for thematic saturation, ensuring the sample met this criterion based on the diminishing need to update code definitions. Our analysis focused on the barriers and facilitators to sustainability of iCPR tool use beyond the study end date. Once all transcripts were coded, we reviewed the data code by code to ensure definitions had remained consistent. All coders then reviewed each excerpt to collectively derive emerging themes related to barriers, facilitators, and recommendations for solutions. Emerging themes were grouped into high-level categories through consensus. This study adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines for qualitative studies involving interviews and focus groups [18].

Results

Descriptive Results

We invited 56 eligible individuals to participate and conducted 22 individual interviews across the 3 sites, each lasting 15 to 45 minutes. Participants included 9 nurses (1 NYU, 8 Wisconsin) and 13 nurse leaders (4 NYU, 2 Utah, 7 Wisconsin); demographic information was not collected from either group. Due to limited tool use during the study, no nursing participants from the University of Utah elected to participate in the interviews.

Through thematic analysis, we identified 5 overarching themes related to nurses' and nurse leaders' perspectives on the implementation, effectiveness, and sustainability of the iCPR intervention as part of standard care processes. The 5 themes that emerged included: (1) importance of staffing stability and capacity; (2) impact of dedicated clinic resource availability; (3) variable nurse readiness with CDS-guided clinical care; (4) influence of openness to change and a nurse-supportive clinic culture; and (5) ongoing need for training and support.

Importance of Staffing Stability and Capacity

One of the most prominent themes concerned the need to have sufficient trained RNs staffed and available in the clinic to support the time needed to triage patients and conduct nurse visits. In addition to nurse staffing, participants emphasized concerns related to physician and support staff levels. Contributing to these concerns, many participants (20, 91%) discussed issues related to staff turnover, including the challenges of retaining staff, training new staff, and implications for using the iCPR tool workflows.

When questioned about barriers to using the iCPR tool, one nurse stated:

> *We are staffed with only three nurses, which is not a lot… One of our nurses left in May of last year to work elsewhere. Then, we hired a new nurse. Our third nurse went on maternity leave. Then when she came back, the other nurse had to leave for other reasons too. We've kind of just been at this [struggle] of not being able to consistently have a good number of staffing.* [N 3.18]

The shortage of nursing support staff often required nurses to cover multiple roles, making it challenging to prioritize tasks and manage workload effectively. One participant stated:

> *…some clinics can't handle it… they don't have enough people to even answer the phones.* [N 3.3]

With full staffing, nurses expressed confidence in executing the iCPRs:

> *We are pretty much fully staffed… it has not been a burden to participate and be a part of this survey and process… it's certainly helped our patients.* [N 3.3]

> *We could have two nurses and visits at the same time and patients aren't having to wait.* [N 3.2]

Additionally, staff turnover was linked to challenges in familiarizing and educating new staff regarding the iCPRs due to limited training time. Increasing awareness among new nurses completing orientation who lacked exposure to the study was discussed. One nurse stated:

> *Now that I'm thinking about it, there's a whole bunch of nurses that started that they weren't probably there when it first started. They don't even know about it, and I don't know if it's part of their orientation packet.* [N 1.7]

A key subtheme involved virtual triage coordination, where nurses working remotely were able to triage patients by phone and monitor clinic appointment availability. Approximately one-quarter of the participants (6, 27%) felt that this workflow disrupted nurse visit appointment availability.

> *It's a small nursing team so you have anywhere from two to three nurses working on a given day and then with the nurses that have the option to work remote now sometimes you only have one RN [registered*

XSL•FO
RenderX

> *nurse] in clinic. That impacts availability for appointments, so I think that is always a challenge.* [N 3.11]

Another participant expressed difficulties coordinating with colleagues not physically in the same place, since the phone triage nurse at Wisconsin and NYU sites was typically different from the nurse who conducts the in-person nurse visit, highlighting staffing coordination in a hybrid care setting.

> *Sometimes, if you're at home triaging the patient, and they could use a nurse visit, trying to coordinate that with colleagues can be hard if it's a busy day. You don't really know what's going on over there [in the clinic]…* [N 3.15]

Impact of Dedicated Clinic Resource Availability

The impact of clinic resource availability, including physical space for nurse visits and scheduling accessibility, was identified as a barrier to uptake of the in-person nurse visit component of the iCPR workflow. The ability to manage the patient care continuum was disrupted when examination rooms were unavailable. One nurse stated:

> *…we don't necessarily have a place to go with our patients…again, sometimes we are just running around trying to find a location for the patient to be assessed in and to complete the visit in.* [N 3.4]

Discussion of the physical clinic setup highlighted that the lack of available examination rooms posed challenges. One RN stated:

> *We've always had to kind of just find a room on the fly for any of our nurse visit types each day, whether they're iCPR or not. A day like today, all of our exam rooms are occupied by the providers that are here. Our plan is just when the patient comes, if there is an available room, just kind of quickly utilize that.* [N 3.18]

Alternatively, when the clinic set aside dedicated rooms for nurse visits and triage, it reportedly streamlined workflows and supported iCPR tool uptake.

> *Structurally, we had a room all ready to do nurse visits that we do for other things. That was easy enough to adopt this [iCPR] into that.* [N 3.3]

> *We have a designated room for nurse visits every day 'cause we have nurse visits every day, and it's an exam room at the front of the clinic, and we have everything that we need in there.* [N 3.10]

Coupled with dedicated room space, time set aside for nursing appointments facilitated iCPR care workflows. One clinic workaround included having patients with sore throats or coughs come in at prescheduled time slots so that nurses and testing resources (such as throat swabs) were available. This allowed the clinic to structure the schedule in a way that allowed nurses to complete patient care activities.

> *I know that one of the things that we tried to focus on and try to do too, as far as our department, is we tried to make sure that we had like the 11:00 and 1:00 p.m. slots available for the nursing and cough and sore throat visits…* [N 3.4]

Variable Nurse Readiness With CDS-Guided Clinical Care

Among RNs who received training, there was variability in their comfort when providing clinical care guided by the iCPR tools. This was expressed as resistance to the delegation portion of the intervention regarding adherence to the iCPRs, staying within their scope of practice, and compatibility with their clinical skills.

Some nurses felt organizational resistance to operationalizing the delegation protocol, which required nurses to practice to the full extent of their qualifications. One nurse leader expressed that the intervention enables nurses to function within the bounds of what they are licensed to do, but existing clinic workflows may not be able to accommodate them.

> *It's asking our nurses to work at the top of our license. The problem is that it takes—the way that they've worked in urgent care for so many years, it causes a change in that workflow…Some of the leaders have been more willing to facilitate that process, and some have not.* [L 2.14]

Nurses expressed discomfort and uncertainty when triaging patients with cough-related symptoms, particularly when required to perform comprehensive respiratory assessments such as auscultating lung sounds. This hesitation often stemmed from fear of missing critical findings and potentially causing harm, which made them reluctant to fully engage with the iCPRs designed for these cases.

> *…there's a lot of nurses who do not like the cough part. They don't like to listen to lungs, and the reason is they're afraid they're going to miss something and harm patients.* [L 3.20]

Educating nurses was highlighted as a potential means of addressing these barriers. One nurse leader shared:

> *Training of new people training is huge, so I think and many people have to be hands on… mixture of hands-on CBT [Computer Based Training] all of that to reach the nurses…but I think training is key.* [L 3.20]

Conversely, nurses reported a strong sense of satisfaction with the sore throat iCPR, noting its simplicity and efficiency, allowing patient assessments to be completed in as little as 15 minutes.

> *The sore throat one we'll use constantly. That is very much something that has been, in my opinion, and I think our providers, everybody really, has been very successful.* [N 3.3]

Influence of Openness to Change and a Nurse-Supportive Clinic Culture

Nurse Factors

A supportive clinic culture, openness to change, and positivity toward nurse support influenced the use and sustainability of

XSL•FO
RenderX

the iCPR-guided nurse delegation workflow. Within clinic culture, the perceptions of support from providers and patients emerged as subthemes, and leadership support was seen as crucial in facilitating the usage of the iCPR tool. Participants reported that leaders who actively listen to nurses and maintain ongoing dialogue foster a supportive environment that encourages new practices. Nurse leaders agreed that supporting staff was a success factor.

> *I think just making sure that staff are feeling confident and comfortable with the process, hearing where there's issues…I think just hearing what the staff is experiencing, trying to support them through any issues that are coming up, and making sure that they're confident in their training to conduct the visits.* [L 3.11]

> *Ongoing discussions with the nursing team to make sure that they feel supported.* [L 3.1]

The overall clinic culture was perceived to be particularly critical. One nurse described the culture of being open to novel processes.

> *…I think that our culture, to use that term for sure, is exceptional in that way. As far as being open to adopting things. Moving forward with nursing skills and nursing involvement in clinic practice is certainly something we focus on as a group and with our leadership.* [N 3.1]

Another participant reported the benefit of a shared value system within the clinic:

> *We have an excellent connection between each other. I think we all work for each other and with each other. There is a shared value system there that was very apparent and that is healthy in many ways… If my boss wasn't that interested in this, I think that we as a group would still be very interested together. We would have just done it by ourselves.* [N 3.1]

Moreover, nurses expressed aspects of professional fulfillment due to spending more time with patients:

> *Talking to the patients is great. Sometimes it's nice, the ones that you talk to, then you get to do a nurse visit.* [N 1.7]

> *Once again, I think it's great for us. It's great for the patient. I think being accessible and giving our patients what they need is—just been a really nice experience.* [N 3.2]

Provider Factors

Factors related to providers were found to be an essential subtheme of the clinic culture. Overall, the provider's acceptability of the processes was viewed as necessary for the sustainability of the iCPR3 tool.

> *We'd have to get the… medical director on board to really get the providers engaged with this. I do feel like providers are one of the bigger barriers. The nursing teams can do this work, but unless we work in collaboration, it'd be pretty hard to have it be sustainable.* [L 2.14]

When medical directors showed interest in teaching and experimenting with new workflows that incurred time savings, the tool's adoption by RNs was supported.

> *If they perceive, or if it's a reality that this program takes visits away from them, rather than gives them more time to see other patients. Then that could be a deterrent and also just their own understanding of how nursing practice can be used. I think in ambulatory it's sometimes disinterested.* [L 1.13]

> *When the doctors like to teach…then it's very helpful. Some doctors… don't even want to do the study…but the ones that want to teach then, that's very helpful.* [N 1.7]

Engagement from a medical director through collaboration was deemed important for facilitating clinic change.

> *It's doable, it's just, again, it's change management. It's really having everybody on board. Probably something that would help it move along better would be all the leaders and medical director meeting and deciding this is the right process….* [L 2.14]

Patient Factors

Patient engagement varied by location and was viewed as tightly connected to the clinic culture. Some nurses reported challenges in communicating the iCPR outcome to patients, especially when the patient had certain expectations connected to receiving antibiotics as part of the visit.

> *We have a low compliance rate in our clinic. When they come to see us, sometimes even when you're like, "You're not gonna see a doctor. You're just gonna see a nurse." They just want to come in and get antibiotics… When they come in and see us, I'm really like, "You're not gonna [get antibiotics]," but sometimes does not go over well with our patient population.* [N 3.10]

A number of issues also described a conflict between the delegation process and the patient's preference for provider type.

> *We do get some that are not interested in having the nurse visit type because they are looking to discuss other remedies or other treatment options, or their complexity medically is sometimes a barrier.* [N 3.18]

> *I think our patient population is different than other clinics. I think that that has made it a little bit harder… We do get pushback from our patients. They're like, 'Well, you're not a doctor,'…*

> *[N 3.10]*

However, some patients appreciated the extra access to appointments and were willing to have a nurse visit and were satisfied with the nurse visit.

> *I feel like patients are very agreeable and willing to come in to see a nurse, after we've explained exactly what's gonna happen… Patients have been really*

XSL•FO
RenderX

> *appreciative. No cost, they get in the same day, which is really what they're looking for…* [N 3.2]

Clinic Communication

General clinic communication was the final subtheme related to clinic culture. A nurse leader expressed interest in having more usage data about the study's progress to communicate with the staff for positive reinforcement.

> *…if people know the why we're doing it that helps…It really comes down to great patient care, antibiotic stewardship, how many visits we did. All of that. I think if we have that data, then as we train, we can bring that forward and show people why we're doing it.* [L 3.20]

Nurse participants also reported satisfaction connected to the receipt of feedback on the iCPR use.

> *I think it's been very positive and we—you guys send out the statistics and it reinforces that we are doing a good job and that always obviously makes me feel good that you are making a difference and… because obviously it's helping everybody. It's helping our patients. It's helping us.* [N 3.2]

Group communication and decision-making as a team were noted as key to the sustainability of clinic initiatives.

> *Again, it's about everyone deciding together that this is the right path and the way we want to go. Then moving it forward as a group so that it's not over here at this clinic but not at this clinic…It's just making sure you've got both nursing and operations, if we're going to really operationalize something and put it into permanent status.* [L 2.14]

Another participant emphasized the importance of teamwork among colleagues, noting the ability to share experiences and seek advice from others to navigate challenges.

> *My co-workers, my colleagues, us working together was another really important piece… Have you done this? Did you run into that?* [N 3.3]

In addition, communication tools were reported to provide support beyond programmatic issues and were seen as helpful in solving acute technology issues.

> *The Webex group was helpful troubleshooting technology issues. They were really good with the patient care part, but, if a technology issue came up, the Webex group was really helpful.* [N 3.6]

Ongoing Need for Training and Support

Participants felt that additional training, specifically hands-on training, would enhance the program's sustainability.

> *… Can we retrain? Can we have champions at the site who can help? Training of new people training is huge, so I think and many people have to be hands-on. Is it a mixture of hands-on CBT [computer-based training]… I think training is key.* [N 3.2]

Another participant reported that recurrent training would help with maintaining skills:

> *Offering skills' refreshers every once in a while if this is gonna be an ongoing thing would be helpful too.* [N 3.15]
>
> *I think education and I think not just a one and done education…at the time of hire, at the time of roll out or sustainability, but then I almost think something yearly just for people to review, ask questions, do hands on skills again* [L 3.20]

In the context of simulation training, a playground or safe, interactive environment was described to bridge this gap, providing a way for learners to practice skills without real-world consequences. One nurse leader was enthusiastic about ways to integrate hands-on training with the iCPR intervention.

> *I would say the hands-on training was fantastic for the nurses. They really appreciated it. It made them feel much more comfortable… in a setting where they can use the playground and practice the swabbing and stuff… making sure we can do a real-world, full-picture visit for practice would be really helpful.* [L 3.6]

Both nurse and nurse leader participants considered nursing leadership support to be part of the sustainability of this program. One of the nurse leaders described their approach as:

> *Just making sure the nurses are comfortable and have the training and education that they need. If the cough part is a barrier, working to get them hands-on training, making sure they've got swabs that they need, stethoscopes that they need, and just being support for them. If they don't have a buddy in the clinic that day, maybe I step in and do it with them.* [L 3.6]

Recommendations Based on Participant Feedback

Participants provided several recommendations to enhance the sustainability of the iCPR tool in nursing practice (Table 1).

XSL•FO
RenderX

Table . Recommendations.

Recommendation	Representative quote
Identify clinic champions	"have champions at the site." "we're going to need a provider champion."
Educate patients	Educate the patients more on "This is what we're doing."
Organize frequent lunch and learns	"circling back to another … skill driven practice type session might be helpful just to make sure … we still feel confident that we can conduct it and not feel too flustered."
Perform triage in advance	"When the first person that gets the [triage] call says, "Oh, they have a cough or a sore throat." That's very helpful because right away it's identified …"
Map physical workflows	"… in the future … you can see the layout of how things are, then you can maybe give a suggestion or tell us something to make a different flow that works somewhere else."
Incorporate into routine practice and policy	"… has to make it a delegation process … more than anything."

Discussion

Principal Findings

The examination of the perceptions of nurses and nurse leaders familiar with the implementation of a CDS-guided nurse intervention for ARIs revealed several barriers and facilitators to the sustainability of the tools' use beyond the conclusion of the study. Factors perceived as contributing to sustainability emerged within 5 themes, including (1) the importance of staffing stability and capacity; (2) the impact of dedicated clinic resource availability; (3) variable nurse readiness with CDS-guided clinical care; (4) the influence of openness to change and a nurse-supportive clinic culture; and (5) the ongoing need for training and support. By touching on the characteristics of the intervention, clinic setting, and individuals, these themes highlight several CFIR domain constructs and strategies at the individual and organizational levels to be considered when seeking to develop a sustainable CDS-guided intervention [15,19]. The most pertinent constructs identified in this research are local attitudes and conditions, partnerships and connections, structural characteristics such as physical and work infrastructure, organizational culture, available resources and space, the roles of innovation deliverers (nurses) and recipients (patients), as well as strategies for tailoring and adapting the use of the iCPR tool.

Individual-Level Strategies

Our analysis highlighted that nurses expressed lower confidence when using the iCPR tool for conditions requiring more complex or subjective clinical assessments, such as listening to breath sounds, compared to workflows perceived as more straightforward, such as visual inspections for sore throat evaluations. Indeed, several participants indicated a preference for sustaining use of the sore throat iCPR workflow only. This gap in confidence suggests a need for targeted skill development. Simulation-based training offers a valuable strategy to build these skills in a realistic, low-risk environment. Regular simulations can help nurses practice nuanced assessments, receive real-time feedback, and strengthen clinical judgment. Incorporating iCPR-related scenarios into onboarding and ongoing education can reinforce competence and confidence. Fostering a culture of continuous learning, with structured supervision and feedback, is essential for supporting effective and sustained implementation [20]. In alignment with CFIR individual constructs [15], the identification of subject matter experts could further assist and support access to information and knowledge.

Organizational-Level Strategies

As seen with many health care interventions, staffing levels were perceived as a key factor influencing long-term sustainability [21]. Inadequate ambulatory clinic nurse staffing impedes staff mastery of new procedures, restricts training time, and hinders comprehension of essential tools, such as EHR CDS modules [22]. Moreover, the increased complexity of ambulatory nursing requires nurse leaders to proactively adjust outpatient staffing models to meet evolving demands [23]. Staffing models were not adjusted to accommodate iCPR3; instead, participating units were only required to have at least one nurse. This model worked well for some clinics but not all. In settings with limited staffing, nurses may be forced to prioritize urgent clinical tasks over engaging with new initiatives, making it difficult to implement interventions effectively. Our findings suggest that a "one size fits all" approach may be inadequate. Instead, staffing models should be tailored to the needs of each clinic, particularly when new interventions are introduced. Due to national nursing shortages, calibrating nurse staffing is more important than ever before [24]. Adequate staffing enables nurses to focus on their patient care activities [24,25], allowing for better adherence to the CPRs. Study participants highlighted encountering challenges integrating new hires, resulting from turnover, and upskilling nurses who have transferred from other specialty areas. Prior to intervention implementation, analyses of turnover rates, percentage of new hires, and overall patient volume should be considered to ensure appropriate staffing availability, aligning with the CFIR construct of general staffing levels to support the functional performance of the inner setting [16]. Strategic planning should incorporate anticipated staffing fluctuations and allow flexibility in response to sudden staffing interruptions. The use of alternative staffing models, such as virtual nursing resources, needs to be considered. While an efficient use of nursing resources in some settings [26], hybrid work environments may contribute to barriers to care coordination and in-person visits.

XSL•FO
RenderX

Availability of clinic resources, especially physical space, was emphasized as a barrier more than expected. Success with the iCPR workflow hinged on ready access to supplies, designated rooms for nurse consultations, a supportive physical layout, and timely provider availability. Compared to inpatient hospital care, the outpatient environment is known to often lack infrastructure support [27]. When nurses had to search for appropriate locations to assess patients upon arrival, both efficiency and patient experience suffered. In contrast, clinics that reserved rooms specifically for nurse visits reported smoother workflows and better outcomes. As per the CFIR physical infrastructure construct, the impact of the layout and configuration of the space affects functional performance [15]. In nonambulatory clinics, similar issues have been previously observed, indicating that both ambulatory and nonambulatory settings face challenges related to resources. Despite progress in CDS tools, considerable barriers remain, especially regarding workflow integration and resource allocation [27]. Future implementations should therefore include a thorough assessment of space and workflow needs, ensuring that dedicated nurse-visit rooms and adaptable layouts are built into the design from the onset [28].

Clinics with positive experiences using the iCPR tools often reported a strong organizational culture characterized by teamwork, openness to change, and leadership that valued nurse autonomy, clinical expertise, and collaborative practice. Supportive leadership and a team-based approach further enabled the effective coordination between nurses and providers required to implement and sustain a new CDS intervention. As recognized by updated CFIR constructs, local attitudes and beliefs influence future use [15]. Participants also emphasized the importance of involving patients in shared decision-making, underscoring the need to respect patient preferences and set clear expectations during care encounters. This finding suggests that fostering a culture that empowers nurses, supports interdisciplinary collaboration, and centers patient engagement may be key elements to the successful nurse adoption of CDS tools in the ambulatory care setting [29].

Recognizing that the iCPR RCT took place in ambulatory settings connected to academic medical centers, there are insights that may translate to nonacademic centers. While community centers may be less resourced for experimentation and have underdeveloped nursing platforms, nurses in nonacademic settings often work at the top of their license out of necessity for patient throughput [30]. Prior to implementing the recommended strategies that connect to our findings, it will be important to compare workload patterns and assess the need for delegation protocols prior to implementing a similar intervention.

Limitations

Several limitations should be noted. This study was conducted within academic medical centers, which are typically characterized by greater infrastructural resources and institutional support, potentially limiting the generalizability of findings for community or resource-constrained settings. Additionally, we did not account for the differences in institutional policies, patient populations, or resource constraints as part of our examination. While thematic saturation was achieved, the final sample size was relatively small, and the sample skewed toward nurses at one site and toward nurse leaders rather than frontline nursing staff, which may have introduced hierarchical bias in perceptions of implementation. However, given low intervention engagement during the RCT at the Utah and NYU sites and that Wisconsin had the most nurses using the tool, we believe the sample was a representative of the iCPR RCT site variability. Participant selection may have been subject to response bias, as we used a convenience sample and did not stratify responses based on participants' familiarity with technology, experience, or frequency of tool usage. Because use of the intervention tools was part of the inclusion criteria, we did not assess the perspectives of nurses who did not perform a nurse visit or who did not participate in the RCT. In addition, participants were recruited and interviewed by known study personnel at their corresponding sites, which may have led to social desirability bias and impacted candor in participant responses. Lastly, this analysis does not include an examination of tool utilization or patient-level outcomes and their influence on perceived sustainability.

Conclusion

This qualitative analysis underscores the multifaceted nature of sustaining a CDS-guided nurse iCPR intervention for ARIs in ambulatory care settings after a formal study period. The findings reveal that sustainability hinges not only on the design of the intervention but also on contextual factors such as staffing adequacy, resource availability, nurse confidence, organizational culture, and ongoing training. Importantly, variability in nurse comfort with CDS tools and differential success across clinic settings suggest that tailored implementation strategies are essential. Future efforts should prioritize clinic-specific readiness assessments, targeted skill development, and leadership engagement to enhance the long-term viability of nurse-led CDS interventions in clinical workflows.

Acknowledgments

The authors wish to acknowledge health care professionals for their professional dedication to patients and their contributions to this project.

Abstract

Background: Nurse turnover remains a major challenge for health systems, yet objective, scalable measures of workload that predict turnover are limited. Electronic health record (EHR) audit logs offer a potential data source to quantify nursing work patterns.

Objective: This study aimed to evaluate the association between EHR-derived measures of nursing workload and turnover among inpatient nurses.

Methods: We analyzed work-related activities of staff nurses from medical and surgical inpatient units at a large academic medical center from January 1, 2022, to December 31, 2022. Data included deidentified demographics (age, sex, years since licensure, and service group), shift characteristics (number of shifts worked, proportion of night shifts, timing, and location), and measures of work activities derived from EHR audit logs. Audit logs were used to develop measures related to nurse workload, including (1) nurse activities (information review, medication administration, alert management, navigation, documentation, and communication), (2) patient load (based on the number of unique patient charts accessed), and (3) cognitive load (based on the number of patient switches). For nurses who left, we excluded the 6 weeks immediately preceding termination (washout period) and measured workload during the preceding 6-week period; for those who remained, a random 6-week working period was selected. Associations between workload measures and turnover were assessed using mixed-effects logistic regression, adjusting for demographics and shift-related characteristics.

Results: Among 432 nurses (n=363, 84% female; median age 27, IQR 23-36 years), contributing 6812 shifts and approximately 13 million audit log actions, 84 (19%) left the institution in 2022. A higher proportion of medication administration actions was associated with higher odds of turnover (odds ratio [OR] 2.20, 95% CI 1.36-3.54), whereas greater alert engagement (OR 0.48, 95% CI 0.32-0.72) and more years since licensure (OR 0.57, 95% CI 0.38-0.84) were associated with lower odds of turnover.

Conclusions: EHR-derived workload measures, particularly greater medication administration burden and lower alert engagement, were independently associated with the risk of nurse turnover. Patterns of EHR use may help identify nurses at higher risk of leaving an institution and can potentially inform targeted workforce retention strategies.

KEYWORDS

electronic health records; nursing workload; clinical informatics; nurse turnover; workforce retention

Introduction

Nurse turnover has increased exponentially over the past decade, posing a threat to health system stability. In the United States, annual turnover rates rose from approximately 18% in 2016 to approximately 29% immediately following the COVID-19 pandemic [1-3]. Globally, the scale of the problem is equally alarming, with similarly high rates of nurses reporting intentions to leave their organizations [4-6]. High nursing turnover destabilizes care teams, increases medication errors, reduces quality of care, and imposes substantial operational and financial burdens on health care systems [3].

Despite the considerable challenges associated with nurse turnover, its underlying drivers remain poorly understood. Prior

XSL•FO
RenderX

work has often linked nurse turnover to factors such as demographics, organizational dynamics [7,8], and workload [1,2,9], primarily relying on observational methods such as surveys, interviews, and focus groups [10-12]. For example, Zheng et al [6] used responses to questionnaires to assess factors such as professional fulfillment, emotional exhaustion, and self-efficacy as contributors to turnover. Other studies have used similar methods to characterize the contributors to nurse turnover and have found high perceived workload, low workplace commitment, poor team collaboration, and lack of recognition from supervisors to be key contributors to nurse burnout and intentions to leave [13,14]. Although these studies provide considerable insights, they depend heavily on self-reported assessments, require significant human effort, and are subject to recall bias, response bias, and limited scalability [1].

Electronic health record (EHR) audit logs offer a scalable approach to quantify nursing workload, capturing time-stamped data on EHR use, including documentation, information review, medication administration, messaging activities, and even indicators of cognitive load such as patient switches and on-screen interruptions [15-17]. However, despite the availability of detailed EHR interaction data from audit logs, little is known about how measures of day-to-day nursing work activities relate to turnover.

In this study, we address this gap by investigating the association between EHR-based measures of nursing workload and subsequent turnover among inpatient nurses at a large academic medical center. By linking nurse work activity metrics with real-world employment outcomes, we aim to provide new insights into how daily clinical work patterns may relate to nurses' decisions to leave their roles.

Methods

Study Setting, Participants, and Inclusion Criteria

This retrospective cohort study included all staff nurses who worked at least 1 clinical shift on a medical or surgical inpatient unit at a large academic medical center in St. Louis, Missouri, between January 1, 2022, and December 31, 2022. Temporary or visiting nursing staff and individuals not officially employed by the hospital were excluded.

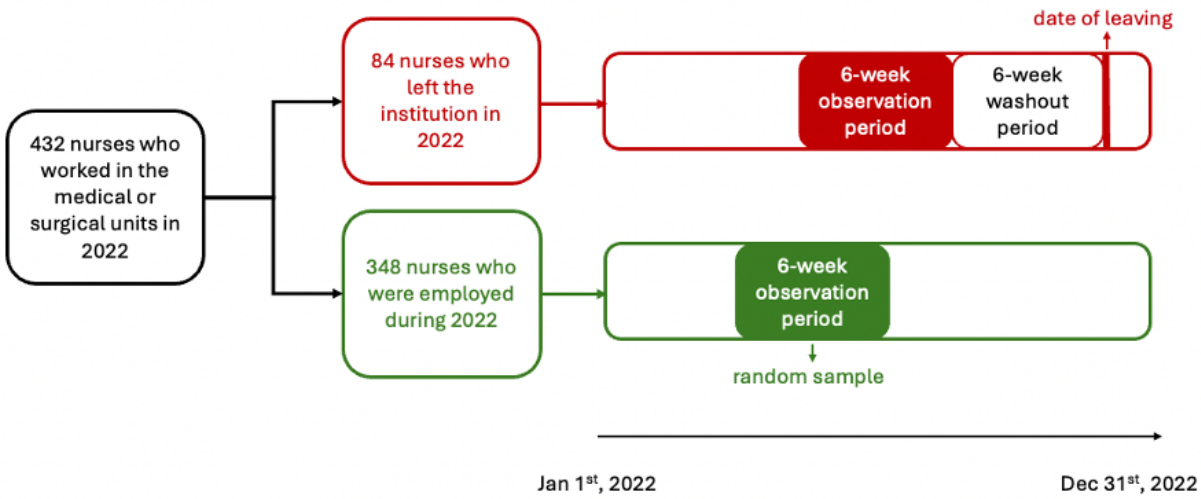
Ethical Considerations

This study was approved by the Washington University Institutional Review Board (IRB#202306138) with a waiver of informed consent. All data were deidentified prior to analysis, and no individually identifiable information was available to the study team. Appropriate measures were taken to protect participant privacy and maintain data confidentiality throughout the study. Participants were not directly involved in the research and did not receive any compensation.

Data Sources

We obtained deidentified data on eligible nurses from three primary sources: (1) employment records, which provided demographic and employment details (age, sex, years since nursing licensure, duration of employment, and turnover status [ie, whether the nurse left the hospital system in 2022]); (2) nurse shift records, which included daily punch-in and punch-out times, nursing unit (eg, general medicine unit, postprocedure unit, or general surgical unit), level of care (eg, acute, intermediate care, or observation), and clinical service group (medical or surgical); and (3) EHR-based audit logs extracted from Epic (Verona, Wisconsin) Clarity tables (ACCESS_LOG), which provide time-stamped records of nurses' EHR interactions and the corresponding patient charts.

Experimental Design



To examine the relationship between EHR-based measures of nurse workload and turnover, we classified nurses into 2 groups: those who left the institution during the 2022 calendar year ("left" group) and those who remained employed throughout the year ("stay" group).

To ensure temporal comparability between groups, we constructed a standardized 6-week observation window for each nurse. The choice of the 6-week period was based on discussions with nursing collaborators across various units rather than on specific empirical evidence.

For nurses who left, we imposed a 6-week washout period before their termination date to avoid capturing behavioral changes occurring after the decision to leave. We then analyzed shifts during the 6-week window immediately preceding the washout period (Figure 1; the red vertical bar marks the date the nurse left, and the filled red bar shows the observation window).

XSL•FO
RenderX

Figure 1. Overall study design. Nurses were grouped into those who were employed at the end of the calendar year (2022) and those who left the institution. For those who left the institution, the date of leaving was used to define a 6-week washout period, and the 6 weeks prior to the washout period were used as the "data period" to calculate the workload metrics. For those who stayed, a random 6-week period during the calendar year was selected for workload metric calculation.

For nurses who remained employed, we randomly selected a 6-week working period during the year-long study period (Figure 1; the filled green bar shows the observation window). This approach ensured consistent observation lengths while minimizing temporal bias and reducing the likelihood that observed behaviors reflected impending departure rather than typical workload.

Data Processing

Each audit log entry included a time stamp, user identifier, patient identifier, and the specific EHR action performed, allowing us to quantify both the frequency and the type of EHR interactions for each nurse during each shift. Audit log events were linked to each nurse's shift by matching time stamps to staffing punch-in and punch-out records, which defined the temporal boundaries for measurement for each shift. To characterize individual nurse workload patterns, we derived shift-level metrics and then summarized these across shifts within each nurse's observation window (ie, 6 weeks).

We first used punch-in and punch-out time records to calculate overall schedule-related metrics for each nurse, including the total number of shifts worked during the 6-week observation period and the proportion of shifts occurring during overnight hours (defined as shifts with punch-in or punch-out times between 7 PM and 7 AM; Figures S1 and S2 in Multimedia Appendix 1). These variables were included to adjust for potential differences in workload and turnover risk associated with shift patterns.

Workload metrics included three domains: (1) EHR-based nursing activities, (2) patient load (with the number of unique patient charts accessed per shift used as a proxy), and (3) cognitive effort (with patient-switching actions used as a proxy) [18,19].

To characterize the composition of EHR-based nursing activities, we relied on prior time-and-motion studies that provided detailed insights into nursing workflows in the EHR [20]. The categorization framework was developed through an iterative process involving audit log experts and clinical domain experts (coauthors LT and SL) familiar with clinical and nursing workflows. Audit log actions were initially mapped to functional task types using vendor documentation and institutional data dictionaries and then refined through multiple rounds of structured clinician review to ensure face validity and interpretability.

Specifically, we categorized EHR actions into 6 EHR-based nursing activities: information review (eg, viewing patient reports, storyboard, and clinical notes); medication administration (eg, barcode scanning, barcode processing, and reviewing administration data); documentation (eg, interacting with flow sheets and clinical forms); workflow navigation (eg, accessing the inpatient system list and loading patient lists); active alert management (eg, acknowledging best practice advisories, reviewing medication warnings, or taking recommended actions); and communication (eg, secure chat communication; refer to Table 1 for category descriptions). Table S3 in Multimedia Appendix 1 provides the complete actions of audit log mapping to activity categories.

XSL•FO
RenderX

Table . Nurse workload categories, their description, and associated example metrics from audit logs[a].

Categories	Description	Example metrics (from audit logs)
Information review	Encompasses nurse activities involving the examination and evaluation of patient-specific data and associated clinical documentation	• Report with patient data viewed • Storyboard viewed • Flow sheet viewed
Medication administration	Involves clinical workflow and procedural tasks required for the administration of medications	• Barcode scanned • MAR[b] barcode processed • MAR administration viewed
Documentation	Activities focused on entering, updating, or interacting with clinical documentation	• Flow sheet accepted • Flow sheet data copied forward • Inpatient work list task edited
Navigation	Actions related to moving through the Epic system to access different functions or patient records	• Visit a loaded Navigator template • Inpatient system list accessed • Radar dashboard accessed
Active alerts	Interactions with system-generated alerts and clinical decision support advisories	• Best practice advisories acknowledged • Medication warning displayed • Patient chart advisories viewed
Communication	Activities using secure messaging apps to facilitate communication and care coordination among the health care team	• Secure chat conversation opened • Secure chat conversation created • Secure chat activity accessed

[a]A full list of the audit logs for each category is provided in Multimedia Appendix 1.

[b]MAR: Medication Administration Record.

We calculated the number of patient switches per shift as a proxy for cognitive effort, reflecting the frequency with which nurses transitioned between patient charts during active EHR use [15,17]. Consistent with prior work, a patient switch was defined as a transition from one patient's chart to another within 5 minutes, to reflect active transitions rather than idle time [17].

Additional workload measures included the total number of EHR actions per shift, the number of unique patient charts accessed per shift (ie, patient load), and time spent using the EHR per shift. Time spent using the EHR, measured in minutes, was calculated from audit log data by summing the time intervals between successive audit log actions, excluding intervals exceeding 5 minutes, which were considered periods of inactivity [18,19].

To summarize these workload indicators at the individual nurse level, we aggregated each nurse's total task-based EHR actions, unique patient charts accessed, and patient switches across the entire 6-week observation period. Specifically, we calculated the proportion of each nurse's EHR actions falling into each activity category by dividing task-specific action counts by the nurse's total EHR actions. For shift-level workload frequency measures, we computed the median value of each metric across all observed shifts for each nurse. Together, these task-based EHR activity proportions and shift-level workload frequency measures served as the primary exposure variables, capturing individual differences in overall EHR-based workload.

Covariates in the regression models included demographic characteristics and shift-related patterns. Demographic characteristics included age, sex, years since licensure, and primary clinical service group. Shift-based factors included the total number of shifts worked and the proportion of night shifts.

All data processing and feature engineering were conducted in Python (version 3.9.10; Python Software Foundation) using the following libraries: Pandas (version 2.2.2) for data manipulation, Matplotlib (version 3.10.3) and Seaborn (version 0.13.2) for visualization, and Scikit-learn (version 1.6.1) and Statsmodels (version 0.14.4) for data preparation [21-26].

Outcome

The primary outcome was nurse turnover, defined as a binary variable indicating whether the nurse left the organization during the 2022 calendar year.

Statistical Analysis

Descriptive statistics were calculated as medians and IQRs or frequencies and percentages. Univariable comparisons between nurses who stayed and those who left were conducted using the Wilcoxon rank-sum test for continuous variables and the chi-square test for categorical variables. Because task-specific action categories are compositional and collectively sum to approximately 100%, we conducted a collinearity analysis using variance inflation factors to assess potential multicollinearity among these variables (Table S1 in Multimedia Appendix 1). On the basis of this assessment and input from clinician experts, the workflow navigation category demonstrated substantial collinearity with other task categories, particularly information review, and was therefore excluded from multivariable modeling to improve model stability and interpretability; information review was retained given its clinical relevance.

XSL•FO
RenderX

To assess the association between EHR-based nursing workload measures and turnover, we used a mixed-effects logistic regression model with random intercepts for nursing units to account for the contribution of each unit's culture and work environment to turnover. The statistical model adjusted for demographic factors (age, sex, years since licensure, and service group), shift characteristics (number of shifts worked and proportion of night shifts), and workload intensity (total EHR actions, patient switches, and number of patients cared for). All continuous predictors were standardized using IQR scaling prior to modeling. Thus, reported odds ratios (ORs) and 95% CIs represent the association with a 1-IQR increase (from the 25th to the 75th percentile) in each continuous predictor.

To assess robustness, we conducted a sensitivity analysis using a shorter 2-week washout period prior to each nurse's departure. Statistical analyses were performed using R (R Foundation for Statistical Computing) with the lme4 package [27].

Results

Sample Characteristics

The analytic sample included 432 inpatient nurses who collectively contributed 6812 shifts and more than 13.8 million EHR audit log actions during the study period (Table 2). Of these nurses, 84 (19%) left the institution (Figure 1). The sample was predominantly female (84%), with a median age of 27 (IQR 23-36) years. In total, 60% (n=259) of the nurses worked on surgical services and 40% (n=173) worked on medical services.

[a]N/A: not applicable.

[b]Indicates statistical significance at the $P<.05$ level.

[c]EHR: electronic health record.

Nurses who left the organization were younger on average (median 26 vs 28 years), although this difference was not statistically significant. They had substantially fewer years since licensure (median 1, IQR 1 - 3 years vs median 3, IQR 1 - 9 years). Sex distribution and clinical service group were similar between groups.

Univariable Analysis

Shift patterns did not differ meaningfully between nurses who stayed and those who left, with a comparable number of shifts worked during the observation window (median 17 in both groups) and similar proportions of night shifts.

Overall EHR workload intensity—including median EHR time per shift, proportion of shift time spent in the EHR, total EHR actions, number of unique patient charts accessed, and number of patient switches—was nearly identical between groups (all $P>.30$).

However, 2 EHR task composition measures differed significantly. Nurses who left had a higher proportion of medication administration actions (median 9.61%, IQR 7.41% - 12.49% vs median 8.54%, IQR 6.44% - 11.69%; $P=.02$) and a lower proportion of active alert engagement (median 0.14%, IQR 0.06% - 0.19% vs median 0.17%, IQR 0.09% - 0.31%; $P=.01$). No significant differences were

XSL•FO
RenderX

observed across other EHR activity categories, including documentation, information review, navigation, or communication (Table 2).

Multivariable Analysis

In mixed-effects logistic regression models adjusting for demographic characteristics, shift patterns, and workload intensity, task composition emerged as the primary workload-related predictor of turnover (Table 3). An increase in the proportion of medication administration actions from the 25th percentile (6.65%) to the 75th percentile (11.98%) was associated with more than twice the odds of leaving the institution (adjusted OR 2.20, 95% CI 1.36 - 3.54). Conversely, an increase in active alert engagement from the 25th percentile (0.09%) to the 75th percentile (0.27%) was associated with substantially lower odds of turnover (adjusted OR 0.48, 95% CI 0.32 - 0.72).

Table . Multivariable analysis showing the association between nursing workload components, demographics, work-related aspects, and turnover.

Variables	Scaled odds ratio (95% CI)	*P* value
Age (years; as of 2022)	1.04 (0.61 - 1.79)	.88
Sex (male vs female)	0.79 (0.39 - 1.59)	.50
Clinical service group (surgical vs medicine)	1.05 (0.53 - 2.07)	.90
Years since licensure	0.57 (0.38 - 0.84)	<.01[a]
Number of shifts worked	0.79 (0.56 - 1.12)	.18
Proportion of night shifts	0.89 (0.47 - 1.67)	.72
Median EHR[b] actions per shift	1.43 (0.80 - 2.54)	.23
Median patient charts accessed per shift	1.07 (0.87 - 1.32)	.53
Median patient switches per shift	0.93 (0.64 - 1.35)	.70
Information review (percentage of total EHR actions)	0.93 (0.44 - 1.96)	.84
Medication administration (percentage of total EHR actions)	2.20 (1.36 - 3.54)	<.01[a]
Documentation (percentage of total EHR actions)	0.95 (0.70 - 1.31)	.77
Active alert (percentage of total EHR actions)	0.48 (0.32 - 0.72)	<.01[a]
Communication (percentage of total EHR actions)	0.96 (0.61 - 1.51)	.86

[a]Indicates statistical significance at the $P<.05$ level.

[b]EHR: electronic health record.

Years since licensure also remained significant; an increase from the 25th (1 year) to the 75th percentile (6 years) was associated with lower odds of leaving (adjusted OR 0.57; 95% CI 0.38-0.84). No other demographic variables, shift characteristics, or workload intensity measures demonstrated significant associations with turnover.

Sensitivity Analysis

A sensitivity analysis using a 2-week washout period before departure produced results consistent with the primary analysis, supporting the robustness of the associations identified (Table S2 in Multimedia Appendix 1).

Discussion

In this study, we investigated the association between EHR-based nursing workload and the likelihood of leaving the institution. We found that fewer years since nursing licensure and performing a higher fraction of medication administration actions were associated with higher odds of turnover. We also found that an increased fraction of active EHR alerts was associated with lower odds of turnover. Taken together, these findings have implications for understanding and potentially redesigning EHR-based nursing workload.

There are several possible explanations for the finding that a higher fraction of medication administration actions was associated with higher odds of turnover. The association of medication administration and documentation with chronic stress and burden has been well-documented [28]. Medication administration is a complex, multistep process involving identifying patients due for medications, prioritizing schedules, accessing centralized dispensing systems, and individually retrieving medications. These tasks may also include secondary nurse verification or additional preparation steps, most of which are not captured in EHR audit logs. Balancing complex medication schedules and performing detailed documentation can lead to mental fatigue and a persistent sense of “catching up” on charting. Over time, this may contribute to emotional exhaustion and increase the likelihood of turnover intention or actual departure [29,30]. During medication workflows, nurses may also encounter various interruptions—from unit alarms to emergency scenarios and interprofessional requests—which further elevate workload and burden [31]. Additionally,

XSL•FO
RenderX

increased medication administration burden may serve as a proxy for higher patient complexity, with sicker patients requiring more frequent interventions, although we could not directly measure patient complexity in this study.

We also found that a higher proportion of active alert engagement was associated with lower odds of turnover. For this study, active alerts were defined as audit log events requiring explicit acknowledgment, often surfacing high-priority safety checks or patient status cues that help structure nurses' decision-making. Nurses engaged with a median of 1.5 active alerts per shift (IQR 1.0 - 3.0), indicating that these events are infrequent and unlikely to represent a significant burden. Rather, they may function as a helpful tool that enhances situational awareness, reinforces clinical priorities, and reduces cognitive load by externalizing key reminders. Therefore, nurses who engage with these alerts may experience greater clarity, support, and alignment with expected workflows, mitigating the sense of chaotic work environments that contribute to turnover. Although we could not differentiate alert types, the small absolute variation in alert fractions across clinicians (0.09% to 0.27%) likely reflects the low frequency of these high-salience events rather than differences in overall workload. Differences in alert engagement may signal how effectively nurses interact with digital workflow supports. Importantly, our model adjusted for demographics, shift type, clinical service, and overall EHR activity, making it less likely that this association reflects underlying workload differences alone. Future work characterizing alert content, cognitive load, and perceived usefulness may clarify whether active alert engagement functions as an indicator of supportive digital environments that promote clinician engagement and retention.

This study has several strengths. It was a longitudinal study that included all nurses at a large academic medical center over 1 year (432 nurses, 6812 shifts, >13 million audit log actions), providing a detailed and objective assessment of EHR-based workload. Our audit log measures captured granular shift-level behaviors, offering a scalable framework to quantify workload patterns that may influence clinician retention. Consistent with prior time-and-motion studies, we found that nurses spent approximately 34% of each shift on EHR activities, including documentation, chart review, and medication management, highlighting the substantial cognitive and administrative demands of modern nursing work [20].

This study also has several limitations. First, this was a single-center study of specific inpatient settings over 1 year. Although we had a large sample, findings may not generalize to other institutions or regions. In addition, the cohort was relatively young (median age 27 years) and in an early career stage (median 2 years since licensure), which may not reflect the broader nursing workforce. Turnover drivers in this population may differ from those in more experienced nurses (eg, career development vs long-term occupational strain), which may influence the observed associations.

Second, audit logs do not capture all aspects of nursing work—such as direct patient care, interpersonal interactions, or work with other technologies (eg, medication-dispensing systems). Thus, our workload measures reflect EHR-based workload only. However, prior research demonstrates that audit logs offer an objective measure of cognitive and administrative workload, capturing a critical aspect of modern clinical practice that can influence clinician engagement and retention [15,32].

Third, our dataset was limited to nurses directly employed by the institution; in other words, the service time only reflected their tenure as employees. If a contingent or agency nurse transitioned to direct employment, their prior service as a nonemployee was not reflected. Furthermore, agency or travel nurses who were not direct employees of the health system were not included in our sample.

Fourth, patient complexity and exact nurse-patient assignments could not be fully accounted for. Patient load was derived from EHR audit logs and operationalized as the number of unique patient charts accessed per nurse, rather than staffing assignment data. Although we adjusted for patient load using this measure and included unit type as a covariate, these proxies may not fully capture patient complexity or staffing patterns. Because nurses may access charts for patients who are not formally assigned to them, this measure may not precisely reflect true patient assignments, introducing potential measurement imprecision. Medication administration–related EHR activity may reflect higher patient complexity, medication burden, or assignment to higher-intensity units rather than workload strain alone, and residual confounding by unmeasured clinical factors (eg, patient acuity) remains possible. Direct measures of patient acuity (eg, case-mix index or high-risk medication exposure) were not available in this dataset.

Fifth, our analysis focused on nurses who fully left the organization and did not include those who transferred internally to other units. To avoid mixing data from prior assignments, our observation window was restricted to each nurse's current unit. Although internal transfers were relatively few, they may still create administrative burden, incur training costs, and pose temporary staffing challenges, which warrants further study alongside complete organizational turnover. Additionally, turnover was defined based on recorded separation from employment, and the reason for leaving (eg, voluntary resignation, termination, or contract completion) was not available, which may introduce heterogeneity in the outcome.

Sixth, workload metrics were aggregated at the nurse level using medians and proportions across shifts to align exposure measurement with a nurse-level outcome of turnover. Although this approach reduces noise in shift-to-shift variability and reflects overall workload exposure during the observation period, it may obscure within-nurse variability, including high-burden shifts. As such, infrequent but extreme workload experiences may not be fully captured. Multilevel shift-based modeling could potentially help in characterizing such patterns.

Finally, we applied a 6-week washout period, based on input from clinical collaborators, to account for the time nurses typically take to decide to leave the organization. We acknowledge that individual decision timelines vary; however, sensitivity analyses using a shorter, 2-week washout period confirmed the robustness of our findings.

XSL•FO
RenderX

Despite these limitations, this study demonstrates a scalable, data-driven approach to quantifying EHR-based nursing workload and its association with turnover. Findings highlight the potential of granular workload measures to identify patterns of digital work allocation that may relate to clinician retention. Future work should integrate direct measures of patient complexity and qualitative assessments of unit culture, interpersonal dynamics, and institutional factors, as well as validate these measures across diverse health systems, to better understand how digital workload interfaces with nurse engagement, burnout, and workforce stability.

Abstract

Background: Patient safety investigation reports support organizational learning only when they are complete, usable, and sufficiently detailed. Conventional free-text reports are often inconsistent and may omit information needed for review and learning. Project NARRATE (Nursing AI-Refined for Accurate Transcription of Events) is a nursing-led ambient artificial intelligence workflow that uses prompts aligned with the World Health Organization Minimal Information Model for Patient Safety Incident Reporting and Learning Systems, Situation-Background-Assessment-Recommendation output, and visible missing-information cues to support structured supervisor reporting.

Objective: This study aimed to compare the completeness and narrative quality of conventional and NARRATE-period supervisor investigation reports for falls and medication administration-related incidents.

Methods: We conducted a retrospective pre-post document-quality study at a tertiary academic medical center in Singapore. We reviewed 150 deidentified completed supervisor investigation reports: 75 conventional reports from June to August 2025 and 75 confirmed NARRATE reports from January to March 2026. NARRATE use was voluntary, and recorded use represented approximately 40% of eligible postimplementation reports. Two blinded reviewers rated reports using a World Health Organization (WHO)–aligned completeness checklist and an adapted 8-domain Physician Documentation Quality Instrument (PDQI). Report-level comparisons were adjusted for repeated reports by the same supervisor using random-intercept linear mixed-effects models. A stratified 60-report plain-paragraph rerating examined whether visible structure influenced ratings.

Results: All 150 reports were analyzed. Unadjusted mean WHO total completeness was 11.81 (SD 3.39) for conventional reports and 13.61 (SD 2.54) for NARRATE reports; the unadjusted difference was 1.80 points, and the cluster-adjusted mean difference was 1.95 (95% CI 0.91 - 3.00; P<.001). The adapted PDQI mean was 3.61 (SD 0.52) and 4.13 (SD 0.34), respectively; the unadjusted difference was 0.52 points, and the cluster-adjusted mean difference was 0.53 (95% CI 0.37 - 0.69; P<.001). In the plain-paragraph sensitivity analysis, the completeness advantage remained (adjusted mean difference 1.70, 95% CI 0.27 - 3.14; P=.02), as did the adapted PDQI mean advantage (adjusted mean difference 0.25, 95% CI 0.06 - 0.43; P=.009). Explanation, organization, and comprehensibility remained significantly higher after deformatting; actions were borderline (P=.05), and synthesis, internal consistency, and fairness/balance were not statistically significant.

Conclusions: Among voluntary early adopters, NARRATE use was associated with more complete reports and higher adapted PDQI mean scores after accounting for supervisor clustering. Because recorded use represented approximately 40% of eligible postimplementation reports and users self-selected, findings may reflect adopter and supervisor characteristics. Results support the structured workflow as a whole, not any single AI component, and do not demonstrate downstream patient-safety effects. Confirmatory evaluation under broader adoption with a concurrent, reliably classified comparison group is needed.

Introduction

Background

Patient safety incident reporting systems support learning only when reports contain enough structured, interpretable information to guide investigation and improvement [1-3]. The World Health Organization (WHO) Minimal Information Model for Patient Safety Incident Reporting and Learning Systems (MIM PS) specifies the elements needed for this purpose, including what happened, why it happened, and what was done in response [2,3].

In practice, many incident reports fall short. Prior studies have found incomplete capture of causal factors, latent conditions, patient impact, and follow-up actions, limiting both case review and system-level learning [4,5]. These shortcomings are not merely documentation defects; they weaken the ability of reporting systems to generate meaningful analysis and improvement [4,5].

Reporting alone therefore does not guarantee learning [6-8]. Interventions that improve the completeness, structure, and usability of investigation narratives may strengthen the value of incident reporting for review and action.

Rationale for the Present Intervention

Ambient AI documentation tools offer one possible response. These scribes can convert spoken narrative into structured draft notes and may reduce documentation burden while improving consistency. Early evaluations of the in-house SingHealth ambient scribe program suggest acceptable note quality and reduced documentation time in outpatient care [9,10]. Whether similar tools improve nursing incident investigation reports remains unclear. To our knowledge, no prior peer-reviewed study has evaluated an ambient AI scribe explicitly aligned with the advanced WHO MIM PS for this purpose.

Study Context

Project NARRATE (Nursing AI-Refined for Accurate Transcription of Events) was developed to improve the quality of completed nursing incident-investigation reports. Built on SingHealth Note Buddy, it prompts supervisors to narrate key WHO MIM PS elements and generates a Situation-Background-Assessment-Recommendation (SBAR)–structured draft. When a safety-critical element is missing, the draft retains a visible missing-information cue for supervisor completion before final submission. The workflow was intended to support more complete, organized, and review-ready documentation while reducing manual reformatting.

We focused on completed supervisor investigation reports rather than initial frontline incident narratives because they contain the postinvestigation information most relevant to learning, including contributing factors, findings, and proposed actions [2,11].

Study Objectives and Hypothesis

This study compared the completeness and narrative quality of completed nursing supervisor investigation reports before and after implementation of the NARRATE workflow. We hypothesized that NARRATE-period reports would score higher on WHO MIM PS–aligned completeness and on an adapted 8-domain Physician Documentation Quality Instrument (PDQI)–based narrative-quality assessment [12]. The primary objective was WHO total completeness; the secondary objective was the adapted PDQI mean; additional objectives included domain-specific and interrater reliability analyses.

Methods

Study Design

We conducted a retrospective pre-post comparative document-quality study, supplemented by a format-blinded plain-text rerating sensitivity analysis in a stratified subsample to assess whether recognizable SBAR structure influenced ratings. The unit of analysis was the completed supervisor investigation report for a nursing-originated patient safety incident. The exposure was documentation method and period: conventional manual documentation before implementation versus NARRATE-supported documentation after implementation. The primary outcome was WHO total completeness, and the secondary outcome was the adapted PDQI mean. We report the study using the SQUIRE (Standards for Quality Improvement Reporting Excellence) 2.0, supplemented by relevant STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) elements.

Setting

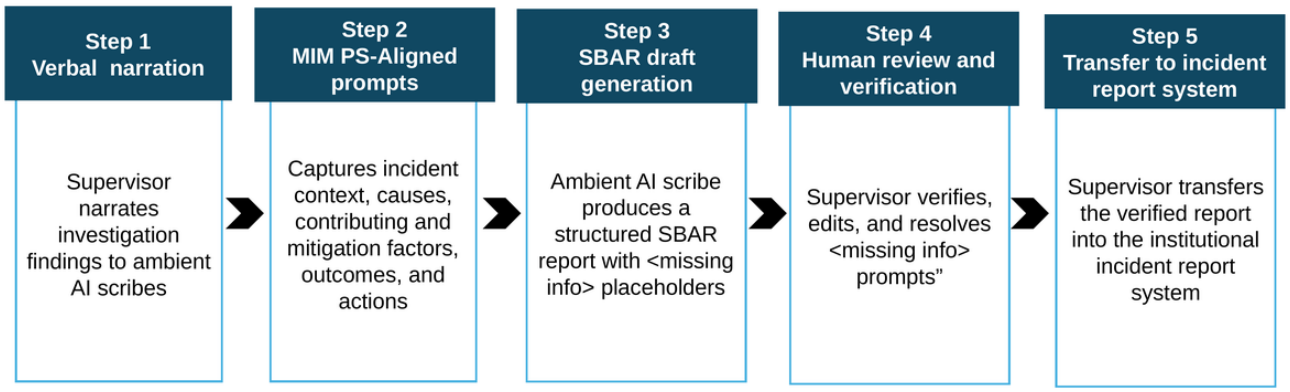
The study was conducted at Singapore General Hospital, a tertiary academic medical center in Singapore, within a nursing-led patient safety documentation improvement initiative.

Intervention: NARRATE Supervisor Workflow

NARRATE stands for Nursing AI-Refined for Accurate Transcription of Events. The intervention used SingHealth Note Buddy, an in-house ambient AI scribe operating within approved institutional digital infrastructure. Note Buddy combines automatic speech recognition with a generative large language model, processes audio in real time, and does not retain audio recordings [10]. Users review and edit draft notes before manually transferring verified content into downstream systems [10].

For Project NARRATE, the team configured a supervisor prompt template aligned with the advanced WHO MIM PS. Supervisors narrated incident context, sequence, outcome, causes, contributing and mitigating factors, and actions; the system generated an SBAR-structured draft [13]. When key elements were missing, the draft retained a visible missing-information placeholder. Supervisors were required to verify, edit, and complete the draft before transfer into the incident reporting system. The workflow treated AI output as documentation support rather than an autonomous investigation conclusion.

AI Governance and Safety Checks



During the study period, NARRATE operated as a stable, postlaunch workflow. The supervisor prompt template was fixed before the study and unchanged throughout, and the underlying

XSL•FO
RenderX

ambient-scribe model did not change during the January to March 2026 window. The underlying platform maintained system-level audit logs of user access and draft-generation activity; these platform logs were not analyzed for this study. Every draft required mandatory supervisor verification and editing, including correction of transcription errors and resolution of all missing-information cues, before transfer into the institutional incident-reporting system.

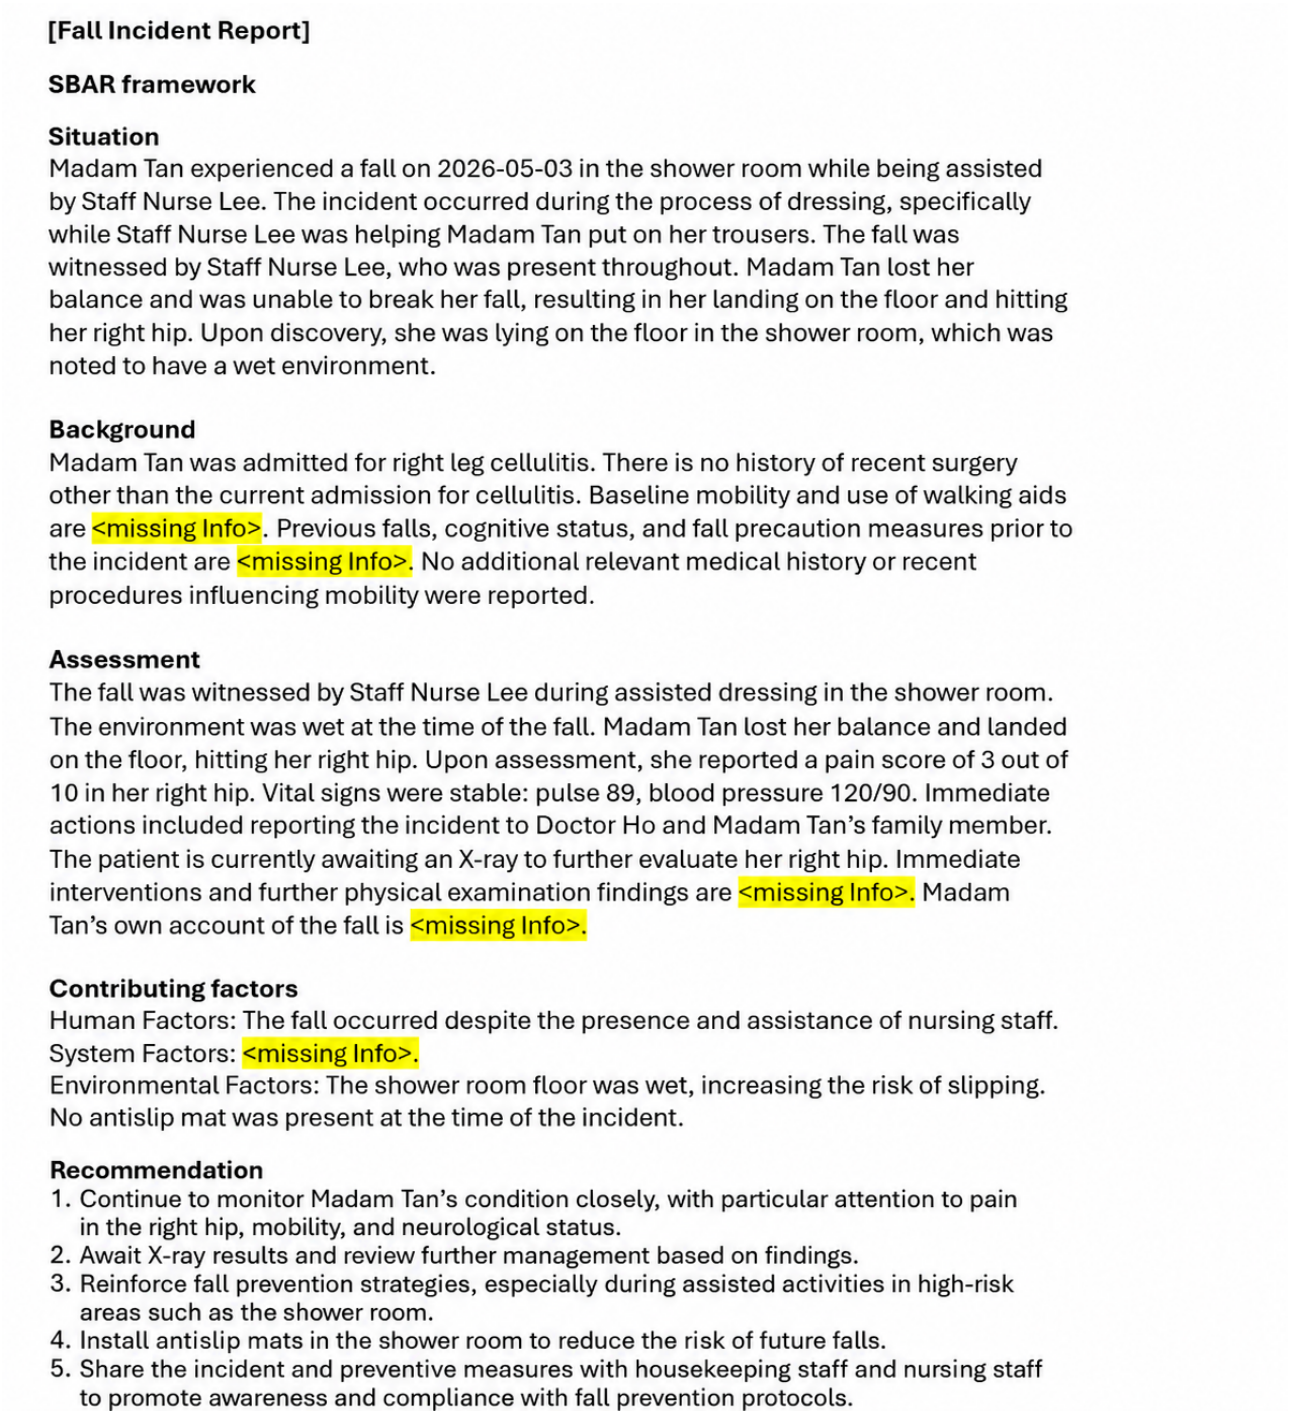


Figure 1 illustrates the supervisor workflow from verbal narration through human verification to final report submission. Figure 2 provides an illustrative example of NARRATE-generated SBAR output with missing-information placeholders.

Figure 1. Project NARRATE (Nursing AI-Refined for Accurate Transcription of Events) AI-assisted supervisor investigation documentation workflow. The workflow moves from verbal narration to World Health Organization Minimal Information Model for Patient Safety Incident Reporting and Learning Systems (MIM PS)–aligned prompts, AI-generated Situation-Background-Assessment-Recommendation (SBAR) draft output, human verification, and transfer to the institutional incident reporting system. Supervisors verify all AI-generated content and resolve any missing-information placeholders before final submission.

XSL•FO
RenderX

Figure 2. Illustrative sample of NARRATE (Nursing AI-Refined for Accurate Transcription of Events)-generated Situation-Background-Assessment-Recommendation (SBAR) output with missing-information placeholders. This example, based on a fictitious fall incident, shows how the AI-generated draft note retains explicit missing-information markers for safety-critical elements requiring supervisor verification. Supervisors are expected to review and address each placeholder before transferring the verified report into the institutional incident-reporting system. All patient and unit details are fictitious.

[Fall Incident Report]

SBAR framework

Situation

Madam Tan experienced a fall on 2026-05-03 in the shower room while being assisted by Staff Nurse Lee. The incident occurred during the process of dressing, specifically while Staff Nurse Lee was helping Madam Tan put on her trousers. The fall was witnessed by Staff Nurse Lee, who was present throughout. Madam Tan lost her balance and was unable to break her fall, resulting in her landing on the floor and hitting her right hip. Upon discovery, she was lying on the floor in the shower room, which was noted to have a wet environment.

Background

Madam Tan was admitted for right leg cellulitis. There is no history of recent surgery other than the current admission for cellulitis. Baseline mobility and use of walking aids are <missing Info>. Previous falls, cognitive status, and fall precaution measures prior to the incident are <missing Info>. No additional relevant medical history or recent procedures influencing mobility were reported.

Assessment

The fall was witnessed by Staff Nurse Lee during assisted dressing in the shower room. The environment was wet at the time of the fall. Madam Tan lost her balance and landed on the floor, hitting her right hip. Upon assessment, she reported a pain score of 3 out of 10 in her right hip. Vital signs were stable: pulse 89, blood pressure 120/90. Immediate actions included reporting the incident to Doctor Ho and Madam Tan's family member. The patient is currently awaiting an X-ray to further evaluate her right hip. Immediate interventions and further physical examination findings are <missing Info>. Madam Tan's own account of the fall is <missing Info>.

Contributing factors

Human Factors: The fall occurred despite the presence and assistance of nursing staff.
System Factors: <missing Info>.
Environmental Factors: The shower room floor was wet, increasing the risk of slipping. No antislip mat was present at the time of the incident.

Recommendation

1. Continue to monitor Madam Tan's condition closely, with particular attention to pain in the right hip, mobility, and neurological status.
2. Await X-ray results and review further management based on findings.
3. Reinforce fall prevention strategies, especially during assisted activities in high-risk areas such as the shower room.
4. Install antislip mats in the shower room to reduce the risk of future falls.
5. Share the incident and preventive measures with housekeeping staff and nursing staff to promote awareness and compliance with fall prevention protocols.

Comparator: Conventional Documentation

In the conventional process, supervisors documented investigation findings manually in free text after reviewing the incident and gathering information from relevant staff or records. Conventional documentation did not include embedded voice-to-text prompts, SBAR-structured AI output, or visible missing-information cues.

Sample, Eligibility, and Selection

We analyzed 150 deidentified completed supervisor investigation reports: 75 conventional reports from June to August 2025 and 75 NARRATE-period reports from January to March 2026. Eligible reports were nursing-originated investigation reports with sufficient narrative text to support scoring. The study focused on falls and medication administration-related incidents.

XSL•FO
RenderX

We excluded duplicates, administrative entries without substantive investigation narrative, and reports outside the study windows. NARRATE operated through the institutional ambient-scribe platform, which is technically separate from the incident-reporting system, and its use could not be mandated within the existing reporting workflow. Adoption during the postimplementation period was therefore voluntary (opt-in), and recorded NARRATE use represented approximately 40% of eligible reports. Supervisors who used NARRATE recorded the corresponding report number in a brief operational record maintained for a separate reporting-time initiative rather than for the present analysis. Entries in this record allowed confirmed NARRATE-generated reports to be identified, but the record was not designed as an exhaustive NARRATE-use registry. Absence from the record therefore could not confirm nonuse. We did not construct a postimplementation non-NARRATE comparison group because a complement-defined group could have contained unrecorded NARRATE reports and introduced exposure misclassification.

From the confirmed NARRATE-documented reports, we drew 75 at random, and we drew 75 conventional reports at random from eligible preimplementation reports. Random selection was applied within each pool to avoid investigator selection of individual reports, but it cannot remove adopter self-selection. Early adopters may differ from nonadopters in documentation practice or motivation. We therefore interpret the comparison as the NARRATE workflow as delivered under real-world voluntary uptake rather than under randomized assignment.

All 150 selected reports were analyzable, with no missing report-level or item-level data.

Sample size was not determined a priori; it was fixed by the number of eligible reports available within the institutional study windows. Accordingly, we frame this power calculation as a minimum detectable effect analysis for a fixed sample rather than as a sample-size justification. Using G*Power 3.1, a sample of 150 reports (75 per group) was sufficient to detect a standardized mean difference of d=0.46 with approximately 80% power at a 2-sided α of .05 [14]; both primary outcomes exceeded this minimum detectable effect. Domain-level and subgroup analyses were exploratory.

Outcomes and Measurement

Completeness Checklist Development and Content Validity

We assessed the primary outcome, report completeness, using a graded checklist derived from WHO technical guidance and aligned with the advanced WHO MIM PS [2,3]. The checklist grouped items into description (what happened and patient impact), explanation (suspected causes, contributing factors, and mitigating factors), and actions (immediate, corrective, and proposed follow-up actions).

Each item was rated 0="absent," 1="partial or insufficient," 2="clear and sufficient for review and learning," or 9="not applicable." Not-applicable items were excluded from the relevant denominator. We calculated WHO total completeness from applicable items and calculated domain subscores as the mean of items within each domain. The full rubric is provided in Multimedia Appendix 1.

Content validity was established through structured review by 3 experts with operational responsibility in patient safety incident review: a Nursing Division patient safety officer, an Office of Patient Safety and Quality manager, and a senior principal pharmacist with medication safety expertise.

Across 2 rounds, panelists evaluated item relevance and contextual appropriateness, and items were refined between rounds. After the second round, all retained items achieved an item-level content validity index of 1.00 [15,16]. The checklist was finalized after the NARRATE prompt template had been locked; the resulting intervention-outcome alignment is addressed in the *Limitations*.

Adapted 8-Domain PDQI-Based Narrative Quality Assessment

We assessed narrative quality using an adapted PDQI approach derived from the PDQI [12]. For this incident-investigation context, 8 domains were scored: thoroughness, usefulness, organization, comprehensibility, succinctness, synthesis, internal consistency, and fairness/balance. Each domain was rated from 1 to 5, and the adapted PDQI mean was calculated as the average of the 8 domain scores. Accuracy was excluded a priori because the ambient AI workflow did not retain an audio record or other source transcript for independent audit, so reviewers could not compare the final report with the original verbal narration or otherwise verify factual fidelity beyond the report text itself. This exclusion matters because ambient AI outputs can contain transcription errors that may propagate into the final note, occasionally with potential for harm [17]; reviewers therefore judged the quality of the final written narrative, not the truth of the underlying investigation. NARRATE drafts were always reviewed and edited by a supervisor before submission. The full rubric is provided in Multimedia Appendix 2.

Reviewer Training, Blinding, and Scoring

Two reviewers from the Nursing Safety and Quality team independently assessed all 150 deidentified reports. Neither reviewer was involved in NARRATE design, prompt authoring, user training, or implementation. Reports were deidentified and masked by an independent data handler. Direct identifiers were removed from the reviewer-facing reports, while a pseudonymous supervisor code was retained separately for clustered analysis. The 2 reviewers had no role in data preparation or access to the linkage information.

Before formal scoring, the reviewers received written rubric guidance and completed iterative calibration on 10 reports outside the study sample; this process also informed refinement of the rubrics in Multimedia Appendices 1 and 2. All calibration-informed rubric refinement, including finalization of the checklist and its item-level content validity index, was completed before any of the 150 analytic reports were rated, so postcalibration rubric drift did not affect the rated sample.

Residual unblinding remained possible because NARRATE-period reports could retain recognizable SBAR structure. This risk was addressed in the plain-text sensitivity

XSL•FO
RenderX

analysis and discussed in the *Limitations*. For the primary analysis, each report was scored independently by both reviewers, and composite scores were calculated as the mean of the 2 ratings after interrater reliability assessment. Individual discrepancies were not adjudicated before the main analysis so that ICC estimates reflected independent ratings.

Statistical Analysis

We prespecified comparisons of preimplementation versus postimplementation reports on the primary outcome (WHO total completeness) and secondary outcome (adapted PDQI [8-domain] mean), with domain-level comparisons treated as exploratory. We reported means and SDs for continuous scores and frequencies with percentages for categorical characteristics.

Interrater reliability for composite scores was assessed using 2-way random-effects, absolute-agreement intraclass correlation coefficients (ICCs), following the framework described by McGraw and Wong [18]. Single-measure ICCs represented the reliability of 1 reviewer's score, and average-measure ICCs represented the reliability of the mean across the 2 reviewers.

To account for supervisors contributing multiple reports, all report-level comparisons were refitted using linear mixed-effects models with documentation method as a fixed effect and a random intercept for the documenting supervisor. Models used restricted maximum likelihood estimation; 95% CIs and 2-sided *P* values used Wald normal-theory inference. Supervisors were nested within documentation method because none contributed reports in both study periods. Adjusted mean differences are reported as NARRATE minus conventional. Unadjusted group means, SDs, and Cohen *d* values calculated using the pooled SD were retained as descriptive standardized effect-size summaries, with approximate 95% CIs derived from the independent-groups variance estimator [19,20].

Because Levene tests had indicated unequal variance for the 2 headline outcomes, exchangeable generalized estimating equations with robust SEs were also fitted as robustness checks; conclusions were unchanged. Statistical significance was evaluated at a 2-sided α of .05. We performed 11 prespecified exploratory domain comparisons in the full-sample analysis (3 WHO subscores and 8 adapted PDQI domains). These comparisons were not adjusted for multiplicity, so the family-wise risk of type I error is increased, and domain-level findings should be interpreted as hypothesis-generating. Original reliability and descriptive analyses were conducted using IBM SPSS Statistics for Windows (version 26.0; IBM Corp); the clustered reanalysis was conducted in Python 3.12 using statsmodels 0.14.6.

Plain-Text Rerating Sensitivity Analysis

Because recognizable SBAR structure could partially unblind reviewers, we conducted a format-blinded sensitivity analysis on a stratified subsample of 60 reports (30 conventional and 30 NARRATE, balanced by incident type) converted to a uniform plain-paragraph format. SBAR labels, section headers, horizontal rules, and other structural cues were removed while preserving report content; an automated audit confirmed that no residual structural markers remained. The rerating used the same 2 reviewers as the main analysis. To prevent reviewers from linking reports to their original SBAR-formatted versions, the data handler (who did not participate in rating) prepared the deformatted set, removed all structural cues, and renumbered and reordered the reports before rerating. Both reviewers were blinded to documentation method and independently rescored all 60 reports using the same WHO completeness checklist and adapted PDQI (8-domain) rubric. Periods were compared using averaged rater scores and the same random-intercept mixed-model approach, with documenting supervisor as the clustering unit; Cohen *d* values were retained as unadjusted descriptive effect sizes.

Ethical Considerations

We analyzed deidentified existing incident-report text generated through routine institutional reporting for this retrospective quality and safety evaluation; the analytic dataset contained no patient or staff identifiers. The retrospective analysis was reviewed under the institutional Quality Assurance/Service Improvement pathway and was determined not to require review by the SingHealth Centralized Institutional Review Board (institutional reference SHS-RSH-CIRB-4234); this determination for retrospective analysis of existing deidentified records was endorsed by the Research Office, Singapore General Hospital, on May 8, 2026. Individual consent was not required because the study used deidentified existing records and involved no direct interaction with patients or staff. We reported the project in accordance with the SQUIRE 2.0 guidelines for quality-improvement reporting, supplemented by relevant STROBE elements; a completed SQUIRE 2.0 checklist is provided in Checklist 1.

Results

Report Sample

A total of 150 nursing-originated supervisor investigation reports were included: 75 conventional and 75 NARRATE reports, covering falls and medication administration-related incidents across both study periods. No cases were excluded. The operational record and associated discussion history identified the documenting supervisor for each selected report. The 75 conventional reports were contributed by 54 supervisors: 39 contributed 1 report, 10 contributed 2, 4 contributed 3, and 1 contributed 4 reports. The 75 NARRATE reports were contributed by 61 supervisors: 49 contributed 1 report, 10 contributed 2, and 2 contributed 3 reports. No supervisor contributed reports in both periods. Sample characteristics by documentation method are summarized in Table 1. The 2 groups were comparable in report length (conventional mean 777, SD 475 words; NARRATE mean 733, SD 254 words; *P*=.49), indicating that NARRATE-period gains were not attributable to longer reports.

Table . Sample characteristics by documentation method (N=150)[a].

Characteristic	Conventional (n=75)	NARRATE[b] (n=75)
Incident type, n (%)		
Fall	41 (55)	45 (60)
Medication administration-related	34 (45)	30 (40)
Sampling period	June-August 2025	January-March 2026
Report length (words), mean (SD)	777 (475)	733 (254)

[a]Report length was calculated as the word count of the event description. Harm-severity tier, ward type, and reporter seniority were not available in the deidentified dataset. Groups did not differ significantly in report length (*P*=.49).

[b]NARRATE: Nursing AI-Refined for Accurate Transcription of Events.

Interrater Reliability

Table 2 summarizes interrater reliability for the composite scores. Agreement was moderate for WHO total completeness and somewhat stronger for the adapted PDQI (8-domain) mean. For WHO total completeness, Cronbach α was 0.829; the single-measure ICC was 0.689 (95% CI 0.577 - 0.772; *P*<.001), and the average-measure ICC was 0.816 (95% CI 0.732 - 0.872). For the adapted PDQI (8-domain) mean, Cronbach α was 0.853; the single-measure ICC was 0.744 (95% CI 0.664 - 0.808; *P*<.001), and the average-measure ICC was 0.854 (95% CI 0.798 - 0.894). Across the 9 WHO items (1350 ratings), reviewers agreed exactly on 957 (70.9%) ratings, differed by 1 category on 285 (21.1%), and differed by more than 1 category on 108 (8%). Larger disagreements clustered in the explanation domain, especially contributing factors (38/150, 25.3%), mitigating factors (23/150, 15.3%), and suspected cause (15/150, 10%), whereas description items showed high agreement (5/150, 3.3% differing by >1 category). To confirm that the explanation-domain advantage was not driven by a single reviewer, we examined each reviewer separately: both scored NARRATE-period explanation content higher than conventional content (reviewer 1, mean difference 0.49, *d*=0.81, *P*<.001; reviewer 2, mean difference 0.17, *d*=0.26, *P*=.11). The direction was therefore consistent across reviewers, although the effect was larger and statistically significant for 1 reviewer and smaller and nonsignificant for the other, consistent with the greater interpretive difficulty of explanation items.

Table . Interrater reliability for composite report-quality scores (N=150).

Outcome	Cronbach α	ICC, single-measure (95% CI)[a]	ICC, average-measure (95% CI)[a]
WHO[b] total completeness	0.829	0.689 (0.577 - 0.772)	0.816 (0.732 - 0.872)
Adapted PDQI[c] (8-domain) mean	0.853	0.744 (0.664 - 0.808)	0.854 (0.798 - 0.894)

[a]ICC: intraclass correlation coefficient; ICCs are 2-way random-effects, absolute-agreement. *P*<.001 for all ICCs.

[c]PDQI: Physician Documentation Quality Instrument.

Primary and Secondary Outcomes

NARRATE reports had higher WHO total completeness scores than conventional reports. The observed mean was 13.61 (SD 2.54) for NARRATE reports and 11.81 (SD 3.39) for conventional reports, corresponding to an unadjusted difference of 1.80 points. After accounting for multiple reports contributed by the same supervisor, the cluster-adjusted mean difference was 1.95 points (95% CI 0.91 - 3.00; *P*<.001). The corresponding unadjusted descriptive standardized effect size was Cohen *d*=0.60 (95% CI 0.27 - 0.93).

NARRATE reports had higher adapted PDQI (8-domain) mean scores. The observed mean was 4.13 (SD 0.34) for NARRATE reports and 3.61 (SD 0.52) for conventional reports, corresponding to an unadjusted difference of 0.52 points. After accounting for multiple reports contributed by the same supervisor, the cluster-adjusted mean difference was 0.53 (95% CI 0.37 - 0.69; *P*<.001) points. The corresponding unadjusted descriptive standardized effect size was Cohen *d*=1.18 (95% CI 0.83 - 1.53). Exchangeable generalized estimating equation robustness analyses yielded similar estimates for WHO total completeness (1.99, 95% CI 0.94 - 3.04; *P*<.001) and adapted PDQI mean (0.53, 95% CI 0.37 - 0.70; *P*<.001). Table 3 summarizes group-level results.

Exploratory WHO Completeness Domain Analysis

Exploratory WHO domain analysis suggested that the overall completeness improvement was driven mainly by explanation and actions (Table 4). In cluster-adjusted models, the description subscore increased only slightly from 1.86 (SD 0.32) to 1.94 (SD 0.18; adjusted mean difference 0.08, 95% CI −0.01 to 0.16; *P*=.07; *d*=0.30), suggesting a ceiling effect. Explanation increased from 1.00 (SD 0.58) to 1.33 (SD 0.51; adjusted mean difference 0.34, 95% CI 0.15 - 0.52; *P*<.001; *d*=0.60), and actions increased from 1.27 (SD 0.43) to 1.43 (SD 0.31; adjusted mean difference 0.19, 95% CI 0.06 - 0.32; *P*=.004; *d*=0.43). Cohen *d* values are unadjusted descriptive effects. These subscore findings should be interpreted as exploratory.

Table . World Health Organization minimal information model for patient safety incident reporting and learning systems–aligned completeness subscores by documentation method (N=150)[a].

WHO[b] domain[c]	Conventional, mean (SD)[d]	NARRATE[e], mean (SD)[d]	Adjusted mean difference (95% CI)[d]	*P* value[d]	Cohen *d*[f] (95% CI)
Description	1.86 (0.32)	1.94 (0.18)	0.08 (−0.01 to 0.16)	.07	0.30 (−0.03 to 0.62)
Explanation	1.00 (0.58)	1.33 (0.51)	0.34 (0.15 to 0.52)	<.001	0.60 (0.28 to 0.93)
Actions	1.27 (0.43)	1.43 (0.31)	0.19 (0.06 to 0.32)	.004	0.43 (0.11 to 0.76)

[f]Cohen *d* values are unadjusted descriptive effects. Domain-level analyses were exploratory.

Exploratory Adapted PDQI (8-Domain) Domain Analysis

Exploratory adapted PDQI (8-domain) analysis showed higher unadjusted scores in the NARRATE group across all 8 measured domains (Table 5). In cluster-adjusted models, differences were statistically significant for thoroughness, usefulness, organization, comprehensibility, synthesis, internal consistency, and fairness/balance. Succinctness improved numerically from 4.31 (SD 0.80) to 4.47 (SD 0.57) but was not statistically significant (adjusted mean difference 0.12, 95% CI −0.12 to 0.37; *P*=.31; *d*=0.23). The largest adjusted absolute increase was in organization, and the largest unadjusted standardized effects were for organization (*d*=2.10), comprehensibility (*d*=1.33), and fairness/balance (*d*=1.32). Fairness/balance nevertheless remained the lowest-rated adapted PDQI domain in both groups.

Plain-Text Rerating Sensitivity Analysis

After reports were re-rendered into a uniform plain-paragraph format and a stratified subsample was rerated, the completeness advantage remained in the cluster-adjusted analysis (adjusted mean difference 1.70, 95% CI 0.27 - 3.14; *P*=.02; unadjusted *d*=0.59, 95% CI 0.08 - 1.11), as did the explanation subscore (adjusted mean difference 0.25, 95% CI 0.05 - 0.45; *P*=.02; *d*=0.63). The actions subscore still favored NARRATE but was borderline (adjusted mean difference 0.16, 95% CI −0.0007 to 0.32; *P*=.05; *d*=0.50). The adapted PDQI (8-domain) mean remained higher in NARRATE reports but attenuated to a moderate effect (adjusted mean difference 0.25, 95% CI 0.06 - 0.43; *P*=.009; *d*=0.64, 95% CI 0.12 - 1.16). Among PDQI domains, organization (adjusted mean difference 0.43, 95% CI 0.19 - 0.67; *P*<.001; *d*=0.92) and comprehensibility (adjusted mean difference 0.45, 95% CI 0.21 - 0.69; *P*<.001; *d*=0.93) remained higher after deformatting, whereas synthesis, internal consistency, and fairness/balance were not statistically significant. These results suggest that the completeness finding and part of the organization and comprehensibility advantage were robust to removal of structural formatting, whereas several other narrative-quality differences were more format-dependent. Cluster-adjusted mean differences, clustered *P* values, and unadjusted effect sizes are summarized in Table 6; corresponding full-sample results are reported in Tables 3-5.

Discussion

Principal Findings

In this retrospective pre-post comparative document-quality study of 150 completed supervisor investigation reports, NARRATE-period reports were more complete and had higher adapted PDQI (8-domain) mean scores than conventional reports. The plain-paragraph sensitivity analysis refined that picture: the completeness advantage and explanation-domain gain persisted after structural formatting was removed, the actions-domain gain attenuated, and organization and comprehensibility remained higher but with smaller effects. By contrast, synthesis, internal consistency, and fairness/balance no longer differed significantly. The most defensible interpretation is therefore improved completeness, explanation content, and some aspects of narrative organization and clarity, with several other narrative-quality differences partly mediated by visible format.

Description was already well documented in conventional reports, which likely limited room for improvement. By contrast, explanation and action content require supervisors to organize findings, identify contributing factors, and specify follow-up, making them more plausible targets for structured prompting [21,22].

Interpretation of WHO Completeness Findings

The completeness findings support prompt-guided documentation aligned to the advanced WHO MIM PS. NARRATE did not appear merely to lengthen or polish reports; it improved the explanatory and action-oriented elements most relevant to review and learning [2,3]. This matters because reports that omit causes or contributing factors are weaker starting points for investigation and root-cause analysis [2,4,23]. By prompting these elements and making omissions visible through missing-information cues, NARRATE may help turn routine supervisor reports into more usable review documents.

The actions-domain gain should still be interpreted cautiously. The effect was modest in the full sample and only borderline in the plain-text analysis, suggesting improved documentation of actions more than proof of stronger action planning itself. Future iterations could prompt more explicitly for system-level actions, accountability, and timelines.

Interpretation of Adapted PDQI (8-Domain) Findings

The adapted PDQI findings require domain-specific interpretation rather than a single claim of globally improved narrative quality [12].

In the full sample, organization, comprehensibility, and fairness/balance showed the largest effects, consistent with the visible SBAR format, which may reduce reviewer cognitive load [13,24,25]. The plain-paragraph sensitivity analysis showed that this pattern was only partly format-driven: organization and comprehensibility remained significantly higher after SBAR labels and structural cues were removed, although both attenuated substantially. By contrast, synthesis, internal consistency, and fairness/balance were no longer significant, and the adapted PDQI (8-domain) mean decreased from a large to a moderate effect.

The narrative-quality findings therefore appear to reflect a mixed mechanism. Some gains, particularly in organization and

XSL•FO
RenderX

comprehensibility, seem to extend beyond recognition of the formatted template, whereas a substantial portion of the synthesis, internal consistency, and fairness/balance advantage is likely format-mediated. This does not make structure unimportant in practice; structured presentation may still improve readability and navigation even if it should not be interpreted here as an independent content gain.

Succinctness was the only PDQI domain without a significant full-sample gain, which is plausible because SBAR summaries and completion prompts can lengthen reports. Even so, succinctness remained high in the NARRATE period, suggesting that improved completeness did not come at the cost of markedly poorer brevity.

Fairness/balance had the lowest mean PDQI (8-domain) domain score in both groups and became non-significant after deformatting. This suggests that fairness in incident reporting depends less on formatting than on investigation depth, avoidance of blame, and adequate attention to system factors [26,27]. The lower variance of adapted PDQI (8-domain) mean scores in the NARRATE group (SD 0.34 vs 0.52) is also a mixed finding: more standardized documentation may improve consistency, but it may also compress idiosyncratic detail that remains useful for review.

Interrater Reliability and Measurement Implications

Interrater reliability was somewhat stronger for adapted PDQI (8-domain) mean than for WHO total completeness, but both composites were within an acceptable range for group-level comparisons. Larger WHO disagreements clustered in the explanation items, which require more interpretive judgment than the more factual description items. These findings support continued use of detailed anchors and suggest that future studies could consider adjudication or consensus scoring for borderline causal items.

Comparison With Prior Work

These findings extend prior concerns that incomplete incident reports limit patient safety learning [4,5]. Rather than evaluating a generic transcription tool, this study examined a workflow that combined voice-to-text capture, WHO MIM PS-aligned prompts, visible omission cues, and SBAR output. The results suggest that prompt-guided narration may improve the capture of learning-relevant elements, although they remain documentation-quality outcomes rather than evidence of reduced harm.

Implications for Nursing Practice, Leadership, and Safety Governance

For nursing leaders, the practical implication is that AI-enabled documentation may be more valuable as a way to improve the quality of incident-review inputs than as a pure efficiency tool [3,4,10,23,28]. When designed to improve the structure, completeness, and usability of investigation narratives, workflows like NARRATE may help supervisors produce reports that are easier to review and more useful for learning.

Implementation should nevertheless preserve professional accountability. Supervisors must verify AI-generated content, correct transcription errors, resolve missing-information placeholders, and ensure that recommendations are clinically and operationally appropriate. Governance should also address confidentiality, responsible AI use, prompt versioning, audit trails, user training, and equity of use across roles and settings [29]. Because accuracy was not assessed, these findings indicate more complete and better-organized reports, not more factually correct ones. No draft-to-final accuracy audit was performed, and accuracy assurance in this workflow rests on mandatory supervisor verification of every draft. Ambient-scribe transcription errors can propagate to the final note, sometimes with potential for moderate-to-severe harm [17]. Completeness and organization gains therefore do not substitute for accuracy assurance and should not be taken as evidence that AI-generated incident narratives can be relied upon without source-data verification in higher-stakes investigations.

Strengths

This study has several strengths: a guidance-informed completeness framework aligned to WHO reporting principles, expert content-validity review of the completeness checklist, a 150-report analytic sample, blinded dual-reviewer scoring with quantified interrater reliability, and parallel examination of both total scores and domain-specific patterns.

Limitations

This study has several limitations. The retrospective pre-post design cannot establish causality, and secular changes cannot be entirely excluded. No additional reporting-quality training or audit-feedback initiative was conducted in the interval, and the institutional incident-reporting system was unchanged; the postimplementation window represented a stable postlaunch period with a fixed prompt template.

NARRATE use was voluntary, and recorded use represented approximately 40% of eligible postimplementation reports. Because the operational record was maintained for another purpose and was not exhaustive, a reliably classified postimplementation non-NARRATE group could not be constructed: absence from the record could not confirm nonuse, and a complement-defined group could have included unrecorded NARRATE reports. The NARRATE group therefore reflects self-selected early adopters, who may differ from nonadopters in motivation, experience, or documentation practice; observed differences may consequently overestimate effects under mandated or universal adoption.

Although the mixed models accounted for correlation among multiple reports from the same supervisor, no supervisor contributed reports in both periods. Documentation method was therefore completely nested within supervisor pool, and clustering adjustment cannot eliminate confounding by different supervisor composition. The comparison cannot fully separate workflow effects from adopter or supervisor characteristics and should be interpreted as performance under real-world voluntary uptake rather than as an unbiased causal contrast. Residual unblinding was possible because NARRATE reports could retain recognizable SBAR structure; the plain-text analysis suggests that some narrative-quality effects were format-sensitive. Because we assessed final supervisor-edited text, we cannot separate the independent effects of transcription,

XSL•FO
RenderX

prompting, missing-information cues, and human editing; effects should be attributed to the workflow as a whole.

The prompt template and completeness checklist were both aligned with the advanced WHO MIM PS, creating intervention-outcome alignment. Because the checklist was finalized after the NARRATE prompt template was locked, this criterion-contamination risk is directional: the checklist could in principle have been shaped by what the prompt already produced. To limit this risk, the content-validity panel evaluated items against WHO MIM PS source guidance rather than the specific NARRATE prompt wording, the checklist graded sufficiency rather than simple field completion, and the adapted PDQI findings partly persisted after deformatting. Nonetheless, confirmatory work using a completeness instrument developed independently of the NARRATE prompts is needed.

The adapted PDQI underwent content adaptation but not full construct validation, and the study assessed documentation quality rather than action quality, timeliness, recurrence, factual accuracy, or patient-safety outcomes. No draft-to-final accuracy audit was performed; accuracy assurance rested on mandatory supervisor verification of every draft. Granular case-mix variables were unavailable, and the study was conducted at a single Singapore tertiary center, limiting causal inference and generalizability.

Future Work

Future work should test whether improved completeness translates into stronger action planning, faster review, better aggregation of contributing factors, and measurable organizational learning. Confirmatory studies should include concurrent, reliably classified nonadopter comparison groups or phased implementation designs that permit within-supervisor comparisons, helping distinguish workflow effects from adopter and supervisor characteristics. Larger multicenter studies could assess implementation fidelity, adoption, and equity across roles and settings. Prospective studies should retain auditable source material so that documentation quality and draft-to-final accuracy can be evaluated together.

Conclusions

Project NARRATE is a nursing-led application of ambient AI documentation support to incident-investigation reporting. Among voluntary early adopters in this pre-post study, NARRATE-supported reports were associated with greater completeness and higher adapted PDQI (8-domain) mean scores after accounting for repeated reports by supervisors, and completeness gains persisted after structural formatting was removed. The findings do not establish that NARRATE alone caused these differences because adopter self-selection and nonoverlapping supervisor pools remain potential explanations. The strongest evidence supports gains in completeness, explanation content, and selected aspects of narrative organization and clarity, whereas several other narrative-quality differences were format-sensitive. Broader prospective evaluation with concurrent controls is required, with AI-generated documentation remaining subject to human verification and governance.

Acknowledgments

The authors acknowledge the nursing supervisors and frontline nurses who contributed to the implementation of Project NARRATE (Nursing AI-Refined for Accurate Transcription of Events) and provided feedback that informed iterative workflow refinement. The authors also thank the expert panel members from Nursing Safety and Quality, the Office of Patient Safety and Quality, and the Medication Safety Committee for their review of the incident report completeness checklist. The authors further acknowledge the support of the SingHealth Digital Empowerment Office, SGH Artificial Intelligence and Automation, and the SingHealth Office of Insights and Analytics in enabling the broader implementation and evaluation of the NARRATE workflow.

The authors used generative AI tools for language editing, organization, formatting support, and manuscript-review suggestions during manuscript preparation. ChatGPT (GPT-5.6 Thinking; OpenAI) supported drafting, editing, and formatting; Claude (Sonnet 5; Anthropic) supported independent review suggestions. The authors reviewed, revised, and verified all scientific content and take full responsibility for the final manuscript.

Abstract

Background: Family care partners manage care for individuals with Alzheimer disease and related dementias (ADRD), including hypertension management crucial for preventing cognitive decline. Nurses frequently interact with these caregiver-patient dyads but have limited evidence about caregivers' real-world experiences of managing this comorbidity. Understanding these experiences is essential for developing nurse-led interventions that support both patients and caregivers.

Objective: This study aimed to explore ADRD care partners' perceptions, experiences, and challenges related to hypertension management. A qualitative thematic analysis of care partner posts from an online forum focused on ADRD was conducted.

Methods: We analyzed 300 posts from ALZConnected, collected using the keywords "hypertension" and "blood pressure." Two independent researchers used reflexive thematic analysis, following the Braun and Clarke framework until data saturation was achieved.

Results: Among posts from predominantly family care partners (10,427/11,092, 94%, mostly adult children), 7 themes emerged: Pharmacotherapy (155/300, 51.7%), addressing medication efficacy, polypharmacy, and side effects; Patient Health Care Implementation Strategies (n=125, 41.7%), encompassing care coordination and provider interactions; Comorbid Care Management (n=136, 45.3%), highlighting caregiving demands, behavioral symptoms of ADRD, and care coordination challenges as barriers to hypertension control; Hypertension Management and Outcomes (n=71, 23.7%), including hypertensive crises; Managing Behavioral Symptoms (n=38, 12.7%), particularly care resistance; Peer Medical Advice Exchange (n=9, 3%); and Caregiver Burden and Self-Care for Hypertension (n=25, 8.3%), revealing care partners' own hypertension attributed to caregiving stress.

Conclusions: Managing comorbid hypertension in ADRD presents challenges spanning medication management, behavioral symptoms, and health care coordination. Caregivers reported developing hypertension themselves, highlighting bidirectional health impacts. Health care providers should implement dyadic interventions addressing both patient hypertension management and caregiver health within the care partnership.

KEYWORDS

Alzheimer disease; dementia; care partner; hypertension; online health communities

Introduction

Background

Alzheimer disease and related dementias (ADRD) affect approximately 7 million Americans aged 65 years and older, projected to reach 13.8 million by 2050 [1,2]. While antiamyloid therapies represent a significant advance as disease-modifying treatments, their clinical impact and accessibility remain subjects of ongoing debate; thus, prevention continues to focus on managing chronic conditions, particularly hypertension, which contributes to cerebrovascular disease, mixed pathology, and potential acceleration of cognitive decline [3-6]. Hypertension serves both as a vascular risk factor for ADRD development and as a highly prevalent comorbidity, with 83% of patients with ADRD experiencing hypertension [7]. Midlife hypertension shows consistent associations with later cognitive impairment and dementia [4,8].

Family care partners provide the majority of care for persons living with ADRD, yet they typically lack formal training in managing complex health needs such as hypertension [9,10]. This gap is particularly concerning because hypertension management encompasses multiple demanding tasks: medication

XSL•FO
RenderX

administration, dietary oversight, exercise encouragement, and blood pressure (BP) monitoring, all requiring knowledge and skills that care partners may not possess.

Nearly half of caregivers providing complex care, regardless of care recipient condition, worry about making mistakes, suggesting low self-efficacy [10]. Research demonstrates that low self-efficacy when managing complex tasks, such as hypertension regimens, is associated with adverse caregiver health outcomes, including depression [11]. Behavioral and psychological symptoms of dementia (BPSD), such as refusal of care, can interfere with care delivery and exacerbate caregiver burden [12-14]. These patterns are consistent with predictions from the stress and coping model [15,16], which posits that caregiver outcomes depend on the dynamic interplay between primary stressors (care demands), secondary stressors (role strain, competing responsibilities), appraisal processes (perceived burden and self-efficacy), and coping resources (social support, problem-solving strategies). Pearlin et al [16] adapted this framework specifically for dementia caregiving, emphasizing how chronic care demands can cascade into secondary stress proliferation, affecting caregiver health and well-being. Within this framework, managing hypertension in ADRD represents a significant primary stressor, one that, when compounded by low caregiver self-efficacy and BPSD, may contribute to the broader pattern of caregiver health decline documented in the literature.

Within this framework, managing hypertension in ADRD represents a significant primary stressor. Nearly half of caregivers providing complex care, regardless of care recipient condition, worry about making mistakes, suggesting low self-efficacy [10]. According to the stress and coping model, low self-efficacy when providing complex care, such as hypertension management, among ADRD caregivers contributes to adverse caregiver health outcomes, such as depression [15]. BPSD, such as refusal of care, can interfere with care delivery and exacerbate caregiver burden [11,12,17].

Care partners performing health management tasks report reduced social participation [13], while those with greater social support experience lower burden [14,18]. Online support communities provide caregivers with accessible platforms for social support, including information seeking, emotional support, and shared decision-making [19-21]. A meta-analysis showed positive impacts of internet-based group support on caregiver social support and self-efficacy [22]. Specifically, this meta-analysis synthesized findings from internet-based group support programs—structured, moderated online interventions designed to deliver peer connection, psychoeducation, and coping skills to dementia care partners via videoconferencing or asynchronous message boards—and found improvements in perceived social support, self-efficacy, and reductions in burden across studies. A scoping review of online support forums further identified ALZConnected [23]—the forum examined in this study—as one of the largest and most active peer-to-peer support communities for dementia care partners, with users exchanging practical advice, emotional support, and shared coping strategies asynchronously [24]. Despite these benefits, peer advice exchanged in unmoderated or lightly moderated forums may include medically inaccurate information, highlighting the need for nurses to understand what care partners encounter and discuss in these spaces.

The psychosocial burdens described above do not occur in isolation from physical health. A growing body of evidence demonstrates that the chronic stress of ADRD caregiving has direct cardiovascular consequences. Older adults who provide care to a spouse or family member with dementia have significantly elevated rates of hypertension compared with noncaregiving peers [25,26]. Longitudinal studies indicate that caregiving stress accelerates the development of hypertension and increases the risk of incident cardiovascular disease, even after adjusting for age and baseline health status [16,26]. Two intersecting pathways explain this elevated risk. First, caregivers may develop hypertension de novo as a physiological response to chronic stress, through sustained activation of the hypothalamic-pituitary-adrenal axis and sympathetic nervous system. Second, caregivers who had pre-existing hypertension often experience worsening BP control as caregiving demands displace time and energy for their own health behaviors, including medication adherence, dietary management, and medical appointments [25]. Despite this dual burden—managing their care recipient's hypertension while their own BP goes unmanaged—caregiver cardiovascular health is rarely addressed in clinical encounters focused on the person with ADRD. Nurses are well positioned to bridge this gap, yet they need a clearer understanding of what care partners experience in managing hypertension across the dyad to design effective, targeted interventions.

Objectives

To our knowledge, no study has analyzed online community health data to explore the dual challenges of providing hypertension management to persons living with ADRD while managing caregivers' own hypertension-related health needs. This study examined 2 interconnected aspects: (1) caregivers' perceptions and challenges in managing hypertension for individuals with ADRD and hypertension and (2) caregivers' own hypertension management challenges contributing to their chronic disease burden. Findings will inform nursing interventions supporting caregiver-patient dyads.

Methods

Study Design

This exploratory qualitative study used reflexive thematic analysis, following the Braun and Clarke (2006) 6-phase framework [27] to explore ADRD caregivers' experiences with hypertension management. This inductive approach allowed themes to emerge from the data rather than imposing pre-existing theoretical categories.

Study Setting and Data Source

Data were extracted from ALZConnected [23], a moderated online community platform established by the Alzheimer's Association. The forum provides message boards where care partners and persons across the ADRD continuum—including those with mild cognitive impairment and established dementia—discuss various topics related to dementia care. This forum represents the heterogeneity of ADRD subtypes rather

XSL•FO
RenderX

than reflecting a particular disease experience. While users must register to post content, all posts are publicly accessible without authentication. At the time of data extraction, 11,092 registered users contributed to the forum, with 94% (n=10,427) self-identifying as family caregivers (n=7,543, 68% adult children; n=1,331, 12% partners/spouses; n=776, 7% other relatives; n=776, 7% grandchildren/siblings);2% (n=222) as professional caregivers; and <1% (n=111) as persons with dementia; and 3% (n=333) did not specify a role.

Data Collection

Posts were extracted via web scraping between May 21 and 28, 2019. We used the search terms “hypertension” OR “ blood pressure” to identify potentially relevant posts, yielding an initial set of 1357 results. Posts were subsequently reviewed to confirm that each referenced both a care recipient with ADRD and the management of hypertension or blood pressure; posts discussing only one of these topics were excluded. From this filtered dataset, we systematically analyzed posts until reaching data saturation at 300 posts.

Ethical Considerations

This study was determined to be exempt from full ethics review by the institutional review board at the University of Texas Health Science Center at Houston (HSC20200784N), as it used deidentified, publicly available online forum data. All forum posts are publicly accessible without authentication, and usernames are pseudonyms; no personally identifiable information was collected or retained.

Data Analyses

Analysis followed a systematic 6-phase process:

- *Phase 1—Familiarization*: 2 trained individuals independently read all extracted posts (n=1357) to gain data immersion.
- *Phase 2—Initial coding*: using manual coding, researchers independently applied open coding to identify meaningful units within posts. An initial codebook containing 14 codes was developed after coding the first 50 posts.
- *Phase 3—Code refinement*: researchers independently coded an additional 100 posts, refining code definitions and identifying 9 additional codes, resulting in 23 total codes.
- *Phase 4—Theme development*: researchers met to review all codes and organize them into potential themes through iterative discussion and consensus building.
- *Phase 5—Theme refinement*: continuing independent coding, researchers achieved saturation at 300 posts, defined as the point at which no new codes emerged across 3 consecutive 25-post batches. All 300 posts were then reviewed to ensure thematic coherence and internal consistency.
- *Phase 6—Theme finalization*: the coding team, including a senior qualitative researcher (with more than 10 years’ experience), met to finalize theme names, definitions, boundaries, and relationships. Disagreements were resolved through discussion until consensus was reached.

Each post could be assigned multiple codes reflecting different dimensions of hypertension management experience. Final themes were organized hierarchically with primary themes and constituent subcodes (Table 1).

XSL•FO
RenderX

Table . Full list of all codes generated from the data.

Code name (number of posts)	Description
Theme 1: Pharmacotherapy (155/300, 51.7%)	
Medication in Hypertension Management (n=94)	Management of hypertension with medication(s). Includes both proper and poor management of hypertension with medication.
Medication Management (n=26)	Caregiver opinion or evaluation of the list of medications a loved one was taking or was prescribed. Includes caregivers having added or removed medications with or without physician approval.
Hypertension Medication Side Effects (n=24)	Side effects presumed from a hypertension medication, such as fainting, dizziness, and falls.
Medication Administration (n=11)	Logistics of medication administration, including ways that caregivers have gotten care recipients to take their medications, such as through the use of pill dispensers or crushing medication into food.
Theme 2: Patient Health Care Implementation Strategies (125/300, 41.7%)	
Care Coordination (n=57)	Coordination of care by the caregiver for an individual with ADRD[a]. Includes topics such as medicolegal issues, finding housing care, and decisions about hiring home care services to ease caregiver burden.
Interaction With Health Care Team (n=30)	Caregiver opinions on their interactions with, or decisions made by, medical personnel (any medical professional or hired caregivers) in charge of or familiar with their loved one's medical needs and care.
Responsibility (n=20)	Where the hypertension care management responsibility falls in terms of who is responsible and how much they are responsible for, such as if the individual with ADRD manages it themselves or if this is put on a caregiver.
Blood Pressure Evaluation (n=10)	Evaluating a loved one's blood pressure by either a physician or themselves as the caregiver. Includes confirmation or reevaluation of a previous hypertension diagnosis or taking a blood pressure reading and evaluating what to do.
Palliative Care Versus Health Management (n=8)	Decision of entering palliative care and how to address hypertension in this stage, if at all. Caregivers also discuss whether or not to continue hypertension medications when in palliative care or hospice.
Theme 3: Comorbid Care Management (136/300, 45.3%)	
Multiple Chronic Conditions Management (n=112)	Having a hypertension diagnosis along with another definitive disease diagnosis, including but not limited to ADRD, physical illness, and mental illness.
Caregiver's Theories About ADRD and Hypertension Relationships (n=13)	Speculation or confirmation of the link between ADRD and hypertension as perceived by the caregiver, author of the post. Discussed either as passing speculation or with supporting articles and reasoning.
ADRD as a Barrier to Hypertension Management (n=11)	How an ADRD diagnosis or its symptoms, such as forgetfulness or anosognosia, affect the care management of hypertension.
Theme 4: Hypertension Management and Outcomes (71/300, 23.7%)	
Hypertensive Episodes (n=23)	Particular occasions, time points, isolated situations, or environments that evoked a temporary elevation in blood pressure. A chronic hypertension diagnosis was not necessary for an episode to occur.
Consequences of Noncompliance (n=12)	Effects of not complying with proper hypertension care, or the consequences of poor or noncompliant hypertension management, such as further disease or adverse health events.
Possible Hypertension (n=11)	Appearance or mention of signs and symptoms of hypertension without simultaneous mention of a concrete diagnosis. Assumed to have hypertension but is not confirmed through the post.
Hypertension as a Side Effect (n=10)	Treatment, medication, or underlying comorbidities that may elicit hypertension as a side effect, such as certain oils or over-the-counter therapies.
Hypertension Exacerbation (n=8)	Situations or stressors, usually chronic, that result in the exacerbation of preexisting hypertension. Does not relate to posts for an undiagnosed person having a hypertensive episode.

XSL•FO
RenderX

Code name (number of posts)	Description
Hypertension to Normotension/Hypotension (n=7)	A person going from explicitly diagnosed hypertension to a state of normal blood pressure or even hypotension. Causes for this can include ADRD progression or as a result of or side effect of medications given.
Theme 5: Managing Behavioral Symptoms (38/300, 12.7%)	
Resistance to Care (n=31)	ADRD individual being resistant to care, creating complications for the caregiver when trying to provide care to their loved one. Anosognosia or disease progression leads to ADRD individuals resisting medical care, medications, appointments, and general management of their care.
Strategies for Compliance (n=7)	Strategies that caregivers employ, create, or discuss in an attempt to get their loved one to comply with care. Strategies often include “fiblets” or white lies to achieve compliance or cooperation in tasks such as visiting the doctor.
Theme 6: Peer Medical Advice Exchange in Online Forum (9/300, 3%)	
Unqualified Medical Advice in a Forum (n=9)	Forum user or caregiver who either takes medical advice from another user on the forum or gives their own medical advice within the forum with intentions to guide or assist another caregiver in the decision-making process.
Theme 7: Caregiver Burden and Self-Care for Hypertension (25/300, 8.3%)	
Caregivers With Hypertension (n=25)	Caregivers discuss their own hypertension, whether this is diagnosed, chronic, acute, spontaneous, or a concern for development in the future. Many caregivers attribute high blood pressure, whether diagnosed or situational, to the stress and demands of the caregiving role.

[a]ADRD: Alzheimer disease and related dementias.

Results

Overview of Thematic Analysis

Through reflexive thematic analysis of 300 posts from the ALZConnected online community forum, we identified 7 major themes reflecting the multifaceted nature of hypertension management in persons with ADRD. These themes captured both care partners’ experiences of managing their care recipients’ hypertension and their own hypertension-related challenges. Table 1 presents the themes, their constituent codes, and frequency distributions. In the narrative that follows, codes within each theme are discussed according to three criteria: (1) frequency—codes appearing in a greater number of posts are given priority to reflect the breadth of care partner experience, (2) prominence—codes that were most central to the theme’s conceptual meaning receive fuller treatment regardless of raw count, and (3) richness of illustrative quotations—codes supported by particularly vivid or representative posts are highlighted to preserve the depth of care partner voice. Where codes were closely related in content or addressed the same underlying experience, they were analytically subordinated under a higher-order code and discussed together to avoid redundancy; this is noted explicitly within each theme narrative below.

Theme 1: Pharmacotherapy (n=155, 51.7%)

Overview

This theme captured medication-related aspects of hypertension management, including efficacy concerns, polypharmacy challenges, side effects, and administration difficulties. Four codes comprised this theme: Medication in Hypertension Management (n=94), Medication Management (n=26), Hypertension Medication Side Effects (n=24), and Medication Administration (n=11).

Medication in Hypertension Management

Caregivers frequently discussed inadequate BP control despite medication use, expressing frustration with treatment failures:

> *She (care recipient) has had very high blood pressure for about 10 years that medication is not controlling as well as it should.*

These posts revealed caregivers’ concern about persistent hypertension despite adherence to prescribed regimens.

Medication Management

Caregivers independently evaluated and modified medication regimens, sometimes without provider consultation. Caregivers expressed skepticism about polypharmacy, perceiving that providers prescribed medications to treat side effects of other medications rather than addressing root causes:

> *My mom was on ten plus meds when she was diagnosed with ALZ/Dementia. I went through them and discovered her doctor was just prescribing meds, many of which were dealing with symptoms of previous meds....Anyway, I had her go cold turkey on the meds [so] we could ease her off of the meds [and] that needed to be done slowly (i.e. Prozac).*

This quote illustrates care partners’ autonomous decision-making regarding complex medication regimens, including the abrupt discontinuation of some medications. Notably, the post does not indicate whether medical supervision was involved, and such decisions may reflect distrust of or limited access to provider guidance rather than the absence of oversight.

XSL•FO
RenderX

Theme 2: Patient Health Care Implementation Strategies (n=125, 41.7%)

Overview

This theme encompassed caregivers' roles in coordinating health care, navigating the health care system, and managing relationships with providers. Five codes comprised this theme: Care Coordination (n=57), Interaction With Health Care Team (n=30), Responsibility (n=20), Blood Pressure Evaluation (n=10), and Palliative Care Versus Health Management (n=8).

Care Coordination Complexity

Caregivers described extensive coordination responsibilities spanning medicolegal arrangements (power of attorney, advance directives), specialist appointments, home care services, and housing transitions. Posts revealed the logistical burden of orchestrating multidisciplinary care:

> *Seven months ago my 66 yo SIL (sister in-law) came to a new state to live with my husband and me after a hospitalization due to a perfect storm of heavy drinking/high blood pressure/dementia. We established her with a new primary care, neurologist and psychiatrist.*

This example demonstrates the extensive coordination required following acute events, including establishing care in new locations and navigating insurance coverage for multiple services.

BP Evaluation

Caregivers discussed conducting home BP monitoring and interpreting readings, often without clear guidance on appropriate parameters or when to seek medical intervention:

> *I've been checking Dad's blood pressure at home like the doctor suggested, but I'm confused about what's actually concerning. This morning it was 158/92, this afternoon 142/88. His doctor said to 'keep an eye on it' but didn't tell me what numbers mean I should call. Is 158/92 an emergency? Do I wait and see if it goes down? I'm keeping a log but honestly don't know what I'm looking for.*

Theme 3: Comorbid Care Management (n=136, 45.3%)

Overview

This theme reflected caregivers' understanding of hypertension as one condition among multiple comorbidities and their perception that ADRD complicated hypertension management. Three codes comprised this theme: Multiple Chronic Conditions Management (n=112), Caregivers' Theories About ADRD and Hypertension Relationships (n=13), and ADRD as a Barrier to Hypertension Management (n=11).

Multiple Chronic Conditions Management

Caregivers described managing hypertension alongside numerous other conditions, revealing the complexity of care for medically complex older adults:

> *My dad is very 'weep', just diagnosed two weeks ago after countless falls and cognitive issues. He has other issues, CPAP machine use, 30 pounds overweight, glaucoma and meds taking for high blood pressure. He also suffers from anxiety*

This quote exemplifies the clustering of chronic conditions (ADRD, hypertension, obesity, glaucoma, sleep apnea, and anxiety) requiring simultaneous management.

Caregivers' Theories About ADRD and Hypertension Relationships

Some caregivers speculated about causal relationships between hypertension and ADRD development, drawing connections between poor vascular health and cognitive decline:

> *Mom has had high blood pressure & cholesterol issues for most of her life so at 79 perhaps this is the result. Lack of blood oxygen to the brain, etc.*

ADRD as a Barrier to Hypertension Management

Caregivers identified cognitive impairment as directly interfering with hypertension self-management by the care recipient with ADRD, including tasks such as remembering medications, understanding dietary restrictions, and recognizing symptoms requiring medical attention:

> *The hardest part is the medication schedule. Mom takes her blood pressure pill in the morning and another one at night, but she forgets constantly. I'll find her pills still in the container at bedtime, or she'll ask me three times in one day if she already took them. Last week, she took her morning dose twice because she couldn't remember taking it the first time.*

Theme 4: Hypertension Management and Outcomes (n=71, 23.7%)

Overview

This theme captured acute hypertensive situations, consequences of poor control, and care partners' observations of BP fluctuations. Six codes comprised this theme: Hypertensive Episodes (n=23), Effects of Hypertension Noncompliance (n=12), Possible Hypertension (n=11), Hypertension as a Side Effect (n=10), Hypertension Exacerbation (n=8), and Hypertension to Normotension/Hypotension (n=7).

Acute Hypertensive Episodes and Stress Reactivity

Caregivers described observing acute BP elevations, often triggered by emotional distress or behavioral symptoms:

> *Decided to check blood pressure since she is so upset and it's off the charts. I try to calm her down and within five minutes or so blood pressure is back to normal. Afraid she is going to have a heart attack or stroke!!*

This quote reveals caregivers' recognition of stress-BP relationships and their fear of acute cardiovascular events.

Consequences of Noncompliance

Caregivers connected medication nonadherence to adverse outcomes, particularly cardiovascular events and dementia progression:

XSL•FO
RenderX

> *Don't want to scare you, but my mom's dementia got worse when she had a heart attack. Her heart attack was caused by high blood pressure because she was taking her meds in a sporadic manner.*

Theme 5: Managing Behavioral Symptoms (n=38, 12.7%)

Overview

This theme addressed BPSD that complicated hypertension management. Two codes comprised this theme: Resistance to Care (n=31) and Strategies for Compliance (n=7).

Resistance to Care

Caregivers frequently described care recipients' refusal of medical appointments, medications, or BP monitoring, often attributing resistance to anosognosia (lack of illness awareness):

> *My mom refuses medical care also. Like your dad she could care less what anyone else is doing or what their opinion is.*

This resistance created significant management challenges, forcing caregivers to balance respecting autonomy with ensuring necessary care.

Strategies for Compliance

Caregivers shared strategies for circumventing resistance, including "therapeutic fibbing" or "white lies":

> *Fib, tell her it's a new program that they are using to train young nurses and caregivers, and her insurance wants her to "volunteer..." worth a shot that worked for my mom. [I] told her the insurance company required these for training and a study, to see if blood pressure taken at home was lower than when taken at the doctor's office.*

Theme 6: Peer Medical Advice Exchange in Online Forum (n=9, 3%)

This small but notable theme captured instances of forum users providing medical advice or recommendations to other caregivers, often without identifying professional credentials or citing evidence sources. One code comprised this theme: Peer Medical Advice (n=9).

Caregivers offered opinions on medication efficacy, treatment decisions, and care strategies based on personal experiences:

> *When I read that your Mom "came back" after only 2 days of restarting the Aricept, it just solidified my opinion that this drug may help more than the Drs even know….Its only been on the market for 12 years, which is not a SUPER long time in the pharmaceutical industry.*

Theme 7: Caregiver Burden and Self-Care for Hypertension (n=25, 8.3%)

This theme revealed caregivers' own hypertension experiences, often attributed to caregiving stress. One code comprised this theme: Caregivers With Hypertension (n=25).

Caregivers disclosed developing hypertension or experiencing BP elevations they directly linked to caregiving demands:

> *I was so frustrated with them and the situation I was literally getting sick myself. I needed counselling myself, my blood pressure went up (now I'm on BP meds); my stomach was always in knots.*

This quote exemplifies the bidirectional perceived health impact of caregiving: care partners not only managed their care recipients' hypertension but also attributed the development of hypertension themselves as a manifestation of chronic stress. The psychosomatic framing ("literally getting sick myself") reflected caregivers' understanding of stress-health connections. Few care partners discussed self-care strategies, suggesting limited attention to their own health needs relative to care recipient needs.

Discussion

Study Overview

This qualitative analysis of 300 posts from the ALZConnected forum revealed that informal care partners of persons with ADRD managing comorbid hypertension navigate multifaceted challenges spanning clinical decision-making, behavioral symptom management, and health care system coordination—often developing hypertension themselves as a consequence of caregiving. These findings illuminate the complex intersection of dementia caregiving and chronic disease management, highlighting both the clinical challenges care partners face and the dual role of online forums as sources of peer support and potential misinformation. Importantly, these findings should be interpreted with attention to the population they most likely represent: caregivers who are digitally engaged, motivated to seek peer support, and comfortable sharing health-related experiences in online communities. This profile suggests a relatively activated, help-seeking subset of the broader caregiving population—one that may have higher health literacy, greater social connectedness, or more access to resources than caregivers who do not engage with online forums. Clinicians and researchers should consider how these characteristics may shape the themes identified and whether caregivers who are less digitally engaged or more socially isolated face additional or distinct challenges not captured in this dataset.

Principal Results

The findings from this analysis reflect the profound daily burdens described in existing caregiving literature while offering additional context about how those burdens manifest specifically in the management of hypertension. Posts in the forum frequently depicted care partners as primary decision-makers for complex, chronic disease management—roles for which many felt underprepared. The co-occurrence of ADRD and hypertension created particularly layered challenges, as cognitive and behavioral symptoms of dementia often complicated adherence to hypertension regimens. That some care partners also reported developing hypertension themselves further illustrates how the caregiving role can blur the boundary between caregiver and care recipient, with implications for how

XSL•FO
RenderX

clinicians conceptualize and address the health of the caregiving dyad.

Comparison With Prior Work

ADRD caregiving places heavy emotional and practical demands on family members. Care partners often spend more than 150 hours per month helping with difficult cognitive and behavioral changes [28]. Caregiving can cause long-term physical and psychological strain and create extra stress in multiple life domains, such as work and family relationships, which may lead to health issues, including hypertension [29]. Research demonstrates that caregiving stress increases the risk of developing hypertension and heart disease [25]. Caregivers experiencing high levels of stress frequently neglect their own health-promoting behaviors and self-care. Studies showed that caregiving duties, lack of energy, and breakdown of social networks lead caregivers to defer their own care [16,26]. The posts analyzed in this study suggest that some care partners may manage both their loved ones' BP and their own, resulting in ongoing health challenges for both.

Major interrelated clinical challenges emerged from the analysis.

The theme of *Pharmacotherapy* revealed patterns of autonomous decision-making, with care partners independently modifying or discontinuing medications without consulting health care providers. For example, care partners described making unilateral decisions about BP medications. Although care partners value their loved one's autonomy in medication management, transitions to care partners taking over medication responsibilities often occur after care partners observe medication errors [30]. Care partners in the online forum frequently reported making decisions about medication changes while facing challenges related to managing multiple medications and complex dosage regimens [31]. These accounts align with research showing that caregivers assisting with medication management are often untrained, underresourced, and unsupported, even though caregivers of persons living with ADRD are often required to manage multiple simultaneous medications and complex regimens [32]. Care partner forum comments suggest that the autonomous decision-making described likely results from several factors: distrust related to perceived overmedication, concerns about certain medications and possible drug interactions, limited understanding of drug effects, and a lack of caregiver-focused medication education during clinical encounters. These findings suggest that nurses may be well positioned to address these concerns by providing caregiver education about medication management, including how to communicate concerns about overmedication with health care providers to avoid risky medication changes.

The theme of *Patient Health Care Implementation Strategies* revealed that care partners in this sample described extensive and often uncompensated coordination work—arranging specialist appointments, navigating medicolegal decisions, managing home care transitions, and monitoring BP without clear clinical guidance on when readings warranted intervention. These findings align with a growing literature documenting that family care partners frequently assume quasi-clinical roles for which they receive little preparation or support [9,10]. The gap between what care partners were asked to do—conduct and interpret home BP monitoring, coordinate multidisciplinary care teams—and the guidance they received during clinical encounters was a recurring source of frustration and uncertainty. These accounts underscore the need for explicit caregiver education at clinical touchpoints, including clear parameters for when to act on home BP readings and how to navigate specialist referral pathways.

The theme of *Comorbid Care Management* revealed that care partners consistently described hypertension not as an isolated condition but as one element of a dense cluster of comorbidities, including obesity, sleep apnea, glaucoma, anxiety, and ADRD itself. This framing reflects the clinical reality of older adults with ADRD, who carry an average of 5 or more chronic conditions simultaneously [4]. Notably, care partners in this forum identified ADRD's cognitive and behavioral features—memory failure, anosognosia, and care resistance—as direct impediments to hypertension self-management by the care recipient. This is an important mechanistic observation: the disease that motivates hypertension management also undermines the patient's capacity to participate in it. Clinicians should anticipate this dynamic and explicitly shift responsibility and education toward the care partner rather than assuming the person with ADRD can self-manage.

The theme of *Managing Behavioral Symptoms* revealed that care resistance—rooted in anosognosia or disease progression—emerged as a substantial impediment to routine hypertension management, including medication administration, BP monitoring, and medical appointments. Care partners described developing workarounds such as therapeutic fibbing to achieve cooperation, reflecting the extent to which they absorbed the clinical burden of managing a patient who could not consent to or comprehend their own care. These strategies, while pragmatically effective, raise ethical questions about autonomy and dignity that care partners were navigating without professional guidance. This theme reinforces the value of behavioral symptom training for care partners and highlights a gap in current clinical practice: the management of ADRD-related care resistance is rarely addressed in the context of chronic disease management protocols.

The theme of *Caregiver Burden and Self-Care for Hypertension* revealed that some care partners shared that they developed high BP or saw their BP rise because of the stress of caregiving, even though this topic only came up in a small number of posts. One caregiver said, "I was literally getting sick myself...my BP went up (now I'm on BP meds)." This quote illustrates how caregiving can affect both the caregiver and the person receiving care. Caregivers often had to handle their loved ones' high BP while also dealing with their own. These accounts are consistent with research suggesting that caregiving can cause ongoing physical and mental strain, leading to adverse health outcomes, including hypertension [29]. Not many care partners discussed their own health or ways to care for themselves, which may be because they focus more on their loved ones' needs than on their own, even though many caregivers have high BP. This pattern means that nurses should consider asking caregivers about their own health during appointments with care recipients, including urging care partners to maintain their own medical appointments. Nurses and other health care providers can check

XSL•FO
RenderX

for caregiver stress and high BP, discuss health risks, and encourage caregivers to prioritize their own self-care. Health care systems might consider developing programs that assist care partners in managing both the daily responsibilities of caregiving and the associated health effects, such as offering stress management, health screenings, and practical support. The Guiding an Improved Dementia Experience (GUIDE) pilot program being offered through Medicare, as well as new billing codes to address the needs of care partners, are important advancements that allow nurses to implement person- and family-centered care to support caregivers [33].

Given these substantial burdens, online support groups have emerged as vital resources where care partners seek social support to buffer against the negative health impacts of caregiving [24]. These online platforms provide accessible spaces for informational, emotional, and peer support among individuals who share similar experiences. Notably, online forums offer care partners safe spaces to disclose experiences that might be stigmatized in offline settings, such as expressions of anger or negative emotions toward the care recipient, with such disclosures typically met with understanding and reciprocal narratives from other group members [34]. According to the stress process model of caregiving, access to social support, such as that from peers, has the potential to improve an individual's appraisal of a stressor and buffer the impact of caregiving demands [16,35]. The forum analyzed in this study functioned as precisely this type of space, where caregivers disclosed their daily struggles with others navigating similar circumstances.

Due to the heavy demands on caregivers, online support groups have become crucial places to find help and connection [24]. These forums provide caregivers with a way to support one another, especially for those who live far from others or have limited time. Research shows that caregivers with the highest needs are often the most active in these groups [34]. Peer support can help caregivers handle stress and feel less alone [35]. The forum in this study served as a venue where caregivers could discuss their daily challenges with others facing similar issues. By sharing their experiences, such as discussing ways to help loved ones take their medicine or finding comfort in each other's stories, caregivers received both helpful advice and emotional support that they might not have otherwise. At the same time, some of the information provided on online forums may not be accurate. Nurses could have a role as facilitators within these forums to provide accurate information and debunk potentially harmful advice.

Across all 7 themes, several cross-cutting patterns emerged that reflect broader systemic challenges in dementia caregiving. Care partners consistently reported unmet informational needs—particularly regarding medication management, behavioral symptom interpretation, and care coordination—that were not adequately addressed during clinical encounters. A recurring consequence was autonomous or underinformed decision-making, in which care partners acted independently due to insufficient guidance from health care providers. Fragmented care coordination further compounded these challenges, with care partners frequently navigating multiple specialists and systems without centralized support. Together, these patterns suggest that the needs of care partners managing comorbid hypertension in persons with ADRD extend well beyond the clinical encounter and underscore the value of proactive, family-centered approaches to chronic disease management in this population.

Limitations

These findings should be viewed in light of several limitations. First, the data come from a single online forum (ALZConnected), so they may not reflect the experiences of all caregivers, especially those who do not use online communities or who use different platforms. Caregivers who post online may differ from those who do not in terms of stress, support-seeking, or health care knowledge. Second, since the forum posts are cross-sectional, we cannot track how caregiving experiences and challenges change over time. Third, limited demographic information about forum users made it impossible to analyze differences by age, gender, relationship to the care recipient, or socioeconomic status. The forum data also lacked race and ethnicity information, limiting generalizability to minoritized communities that may face distinct caregiving burdens and health disparities; future studies should intentionally recruit diverse samples. Additionally, we were unable to verify the specific etiology of care recipients' dementia (eg, Alzheimer disease vs vascular or mixed pathology) or other clinical details, which may influence caregiving challenges and the relevance of hypertension management. Fourth, geographic data were unavailable, limiting interpretation of findings related to access to care. Fifth, the self-reported, unverified nature of online forum posts introduces self-report and potential reporting bias. Sixth, the search strategy relied exclusively on fully spelled-out terms ("hypertension" and "BP") and did not include common medical abbreviations such as "hypertension," "BP," "systolic blood pressure," or "diastolic blood pressure." Caregivers with greater medical familiarity or clinical backgrounds may preferentially use these abbreviations, and potentially relevant posts from more health-literate users may therefore have been excluded from the dataset. This represents an additional source of selection bias that could skew findings toward caregivers with less clinical knowledge, and future studies should test whether abbreviation-based search terms yield meaningfully different or additional posts. Finally, thematic analysis is inherently interpretive; future mixed methods studies linking qualitative themes to clinical or registry data would strengthen validation of these findings. Prospective studies with comprehensive demographic data and registry-based diagnosis verification are needed to address these limitations.

Conclusions

This analysis of online forum posts shows that care partners for people with ADRD and high BP face many challenges, such as handling medications, managing difficult behaviors, working with the health care system, and dealing with their own health. In the current sample, care partners frequently reported making medication-related decisions independently, struggled to differentiate between transient and chronic BP elevations, and sought ways to manage care resistance associated with anosognosia. These findings highlight significant gaps in the training and support available to caregivers. Health care

XSL•FO
RenderX

providers and systems should recognize that care partners are essential members of the care team, but they often lack the preparation and support they need.

Future research should investigate ways to address the challenges highlighted here, such as training programs for care partners on medication management, tools to aid in interpreting BP readings, and methods for managing care resistance in individuals with limited awareness of their illness. Long-term studies could help us understand how caregivers' needs change as dementia progresses. Research on how professional moderators influence online support communities could help identify the most effective ways to support caregivers and prevent the spread of incorrect information. Additional studies are also needed to examine caregivers' heart health and whether targeted programs can help prevent or manage high BP in caregivers.

By learning from the experiences shared in these online forums, health care providers and systems can better support care partners in their crucial role and attend to their own health needs. Equipping care partners with targeted education, care coordination support, and access to reliable health information represents a meaningful step toward addressing the dual burden documented in this study.

Abstract

Background: Health care professionals are exposed to high levels of occupational stress, emotional exhaustion, and anxiety-depressive symptoms. Digital interventions using mindfulness- and acceptance-based approaches have shown promising results in improving psychological well-being in this population. The MINDxYOU program is a self-guided digital intervention designed to reduce perceived stress and enhance emotional regulation, resilience, and psychological flexibility. Although its effectiveness has been demonstrated, treatment response may vary substantially between individuals.

Objective: The aims of this study are to explore the sociodemographic, occupational, and psychological moderators of the effectiveness of the digital MINDxYOU program on perceived stress among health care professionals and to identify differential response profiles.

Methods: This study is a secondary analysis of a stepped-wedge cluster randomized trial including 347 health care professionals from 6 clusters allocated to 3 intervention start sequences. The intervention (MINDxYOU) is a self-guided, web-based program designed to be completed over 8 weeks, grounded in third-wave psychological approaches and incorporating mindfulness-, compassion-, and acceptance-based components. Weekly support was provided via WhatsApp Messenger (Meta Platforms Inc), phone calls, or email to promote adherence. Assessments were conducted every 8 weeks across 5 measurement waves. Linear mixed-effects models were used to evaluate moderation effects by testing condition × moderator interactions, accounting for repeated measures within participants and clustering effects.

Results: Moderation analyses showed greater reductions in perceived stress among participants with higher baseline depressive symptom scores (9-item Patient Health Questionnaire [PHQ-9]; B=−0.22, SE 0.08; *P*=.004) and those with higher scores in the observing facet of mindfulness (15-item Five Facet Mindfulness Questionnaire [FFMQ-15]; B=−0.86, SE 0.41; *P*=.04). In addition, nursing staff exhibited greater reductions in perceived stress compared with physicians (B=1.92, SE 0.81; *P*=.02) and other health care professionals (B=1.80, SE 0.90; *P*=.04).

Conclusions: The results suggest that baseline psychological and occupational characteristics may contribute to differences in the effectiveness of the MINDxYOU program in reducing perceived stress. These findings provide preliminary evidence regarding

XSL•FO
RenderX

potential response profiles in digital mental health interventions and support the development of more personalized and targeted approaches to stress management in health care settings.

KEYWORDS

perceived stress; health care professionals; digital intervention; mindfulness; depression; resilience; mental health

Introduction

The increasing levels of occupational stress among health care professionals represent a growing public health concern, with implications at both the individual and organizational levels. Prolonged exposure to high emotional demands, work overload, extended shifts, and ethical conflicts generates emotional exhaustion, compassion fatigue, and a high risk of burnout [1,2]. This situation has worsened in recent years due to the COVID-19 pandemic, which intensified health care pressure and increased levels of anxiety, depression, and psychological distress among health care workers [3,4].

The impact of chronic stress in this population affects not only professionals' well-being but also quality of care, patient safety, and the sustainability of health care systems. Recent studies have shown that workers experiencing high levels of burnout are more likely to commit medical errors, show reduced empathy, and report greater intentions to leave the profession [5]. In this context, promoting the mental health and psychological resilience of health care professionals has become a strategic priority at both the institutional and scientific levels.

Stress-reduction programs delivered face-to-face have demonstrated effectiveness; however, their implementation is often limited by time constraints, rotating shifts, and the emotional demands inherent to clinical practice. In this context, digital interventions based on third-wave cognitive behavioral therapies, such as acceptance and commitment therapy, mindfulness-based interventions, and compassion-focused approaches, have demonstrated effectiveness in reducing psychological distress and improving emotional coping across different occupational and clinical settings [6,7]. These digital interventions offer several advantages, including greater accessibility, lower costs, and scalability, which facilitate their implementation in high-demand health care environments [8]. Recent evidence has further highlighted the potential of digital mental health interventions to support workforce well-being and address unmet mental health needs in occupational settings [9-11]. These findings are particularly relevant in health care settings, where digital interventions have demonstrated promising effects on stress reduction, burnout prevention, and psychological well-being among health care professionals [9,10,12-14].

Within this framework, MINDxYOU was developed as a self-guided digital program designed to promote emotional self-regulation, acceptance, and resilience among health care professionals. Results from a stepped-wedge cluster randomized trial demonstrated that MINDxYOU significantly reduced levels of stress, anxiety, and depression in this population [12]. A subsequent mediation analysis revealed that improvements in resilience constituted a significant psychological mechanism underlying the observed intervention effects [15].

However, even when interventions show overall effectiveness, treatment response may vary substantially across individuals, with previous studies also showing substantial heterogeneity in the outcomes associated with this type of intervention [16]. Increasing attention has been devoted to identifying the moderators of treatment effects, defined as personal or contextual characteristics that determine for whom and under which conditions an intervention is the most effective [9,17]. This approach has gained increasing relevance in digital mental health research, where recent evidence highlights personalization and adaptive intervention strategies as key factors for improving intervention effectiveness, engagement, and implementation outcomes [17-19].

Although the MINDxYOU program has shown beneficial effects in reducing perceived stress among health care professionals, less is known about whether these effects may differ according to participants' baseline characteristics. Exploring potential sources of variability in response is relevant for advancing the personalization of digital mental health interventions and for improving their applicability in health care settings. Therefore, the present study aimed to examine whether individual, psychological, and occupational characteristics were associated with differential responses to the MINDxYOU program in terms of perceived stress reduction.

Methods

Design

This study followed a stepped-wedge cluster randomized trial design, in which 6 clusters of health care professionals were randomly assigned to 3 intervention start sequences. Each sequence began the intervention at different time points separated by 2-month intervals, ensuring that all groups eventually received the program. This design allowed comparisons between participants who had not yet accessed the intervention and those who had already completed it while maintaining temporal control of the intervention effects.

Participants

The sample included 347 health care professionals. Inclusion criteria were (1) employment as a health care professional (eg, physician, nurse, psychologist, or nursing assistant) or enrollment in training in any health-related field, (2) age between 18 and 70 years, (3) ability to understand Spanish, (4)

XSL•FO
RenderX

digital literacy and access to an internet-connected smartphone, tablet, or computer, and (5) expected continued employment in the same workplace for the following 6 months. Participants with incomplete data in the main study variables or with significant changes in their employment status during the follow-up period were excluded.

Participants were grouped into 6 clusters according to their workplace, and these clusters were randomly assigned to an intervention sequence (MINDxYOU) using a computerized simple randomization procedure. Assessments were conducted every 8 weeks across 5 time points throughout the study. At each measurement point, participants completed the same self-report questionnaires through the program's digital platform.

Intervention

The MINDxYOU program is a self-guided, web-based intervention consisting of 4 modules delivered over 8 weeks, integrating mindfulness-, compassion-, and acceptance-based strategies. Content was delivered through videos, audio-guided practices, and interactive exercises. Participants received weekly support via WhatsApp Messenger (Meta Platforms Inc), phone, or email to promote adherence. In the stepped-wedge design, participants in the control condition were placed on a waiting list and received the intervention at later time points. Further details on the intervention components, module contents, and delivery procedures are provided in the study protocol [20].

Ethical Considerations

The study protocol was approved by the Research Ethics Committee of the Autonomous Community of Aragon and the Ethics and Research Committee of Northeast Malaga in July 2022 (approval code PI22/341). All participants provided informed consent prior to participation, and the study was conducted in accordance with the Declaration of Helsinki and European data protection regulations [21].

Measures

In the MINDxYOU clinical trial, a comprehensive set of self-report instruments was administered to assess clinical and psychological variables. Detailed information regarding the structure, reliability, and validity of these measures is described in the study protocol [20].

The primary outcome was perceived stress, assessed using the 10-item Perceived Stress Scale (PSS-10; [22]; Spanish version [23]). Secondary outcome variables included (1) depressive symptoms, assessed with the 9-item Patient Health Questionnaire (PHQ-9; [24]; Spanish version [25]); (2) generalized anxiety, measured with the 7-item Generalized Anxiety Disorder ([26]; Spanish version [27]); and (3) general psychological symptoms, assessed using the 18-item Brief Symptom Inventory ([28]; Spanish version [29]).

Regarding psychological processes associated with change, mindfulness was assessed using the 15-item Five Facet Mindfulness Questionnaire (FFMQ-15; [30]; Spanish version [31]). Psychological resilience was measured using the Connor-Davidson Resilience Scale (CD-RISC; [32]; Spanish version [33]). Compassion and self-compassion were assessed using the Sussex-Oxford Compassion Scales ([34]; Spanish version [35]) and the Acceptance and Action Questionnaire-II ([36]; Spanish version [37]).

Variable Selection

The selection of moderator variables was conducted in several stages. First, a panel of researchers defined an initial set of potential moderators based on the previous literature on stress-reduction programs for health care professionals and on the theoretical plausibility of the programs' relationship with treatment response [38]. Subsequently, a correlation matrix was examined to assess the relationships between baseline variables and perceived stress symptoms. To avoid problems of multicollinearity and conceptual redundancy, priority was given to variables that showed moderate correlations with baseline perceived stress symptoms while representing distinct psychological or contextual constructs. Variables with correlations greater than r=0.65 were excluded.

Following this procedure, a final set of moderators was defined, including (1) sociodemographic variables, including age and gender; (2) work-related variables, including type of contract (temporary vs permanent), occupation (physician, nurse [nurse or nursing assistant], or other health care professional), management position (yes/no), and workplace setting (hospital, primary care center, nursing home, or other); (3) clinical variables, including depressive symptoms measured with the PHQ-9; and (4) process variables, including psychological resilience, measured with the CD-RISC, and the observing facet of mindfulness, assessed with the FFMQ-15.

Additionally, variables related to the intervention were analyzed separately in order to explore whether the level of participation and the timing of intervention initiation influenced treatment outcomes. These variables included the intervention sequence, corresponding to the different start times established by the stepped-wedge design. Adherence was also considered and was defined as completion of at least 3 (out of 4) modules among participants who initiated the program.

Thus, the main set of moderators included sociodemographic factors, occupational factors, clinical factors, and process variables, while intervention-related variables were analyzed in a separate block to provide complementary information regarding the role of program use and adherence in the effectiveness of the intervention, as well as the potential influence of delayed initiation of the intervention across sequences.

Statistical Analysis

Data were analyzed using linear mixed-effects regression models to account for the longitudinal and clustered structure of the data. Repeated assessments were nested within participants, and participants were clustered within health care centers. The primary outcome was the PSS-10 total score. For each potential moderator, a separate mixed-effects model was fitted. Each model included the condition (intervention vs control), the moderator, and the condition × moderator interaction as fixed effects. The interaction term was used to test whether the effect of the intervention on perceived stress differed according to the baseline value or category of the moderator. All models were adjusted for baseline PSS-10 score and assessment time.

XSL•FO
RenderX

Random intercepts were specified at the participant and cluster levels. Collinearity among baseline predictors was examined using a correlation matrix before fitting the models. All potential moderators were then entered into the same multivariable mixed-effects model. This model was used to examine whether each moderator was independently associated with a differential intervention response after adjusting for the remaining moderators. Intervention-related variables, including intervention sequence and adherence, were analyzed separately using mixed-effects models adjusted for the same baseline covariates. All analyses were conducted in R software (version 4.4.1; R Foundation for Statistical Computing) using the *nlme* and *lme4* packages [39]. A 2-tailed significance level of .05 was adopted for all statistical tests.

Results

Sample Characteristics

The final sample consisted of 347 health care professionals, including 297 (85.6%) women with a mean age of 45.01 (SD 11.2) years. Participants were classified as physicians (n=147, 42.4%), nursing staff including nurses and nursing assistants (n=93, 26.8%), and other health care professionals (n=107, 30.8%). Further details of the baseline characteristics of the overall sample and across the randomized intervention sequences are presented in Table 1.

[f]Two missing values.

Moderation Analysis

Professional occupation showed a significant moderation effect. Using nursing staff as the reference category, physicians (B=1.92, SE 0.81; *P*=.02) and other health care professionals (B=1.80, SE 0.90; *P*=.04) exhibited smaller reductions in perceived stress following the intervention. Further details of the univariate moderation analyses are presented in Table 2. Figure 1 graphically illustrates the changes in perceived stress levels during the preintervention and postintervention periods across professional groups.

[e]FFMQ-15: 15-item Five Facet Mindfulness Questionnaire.

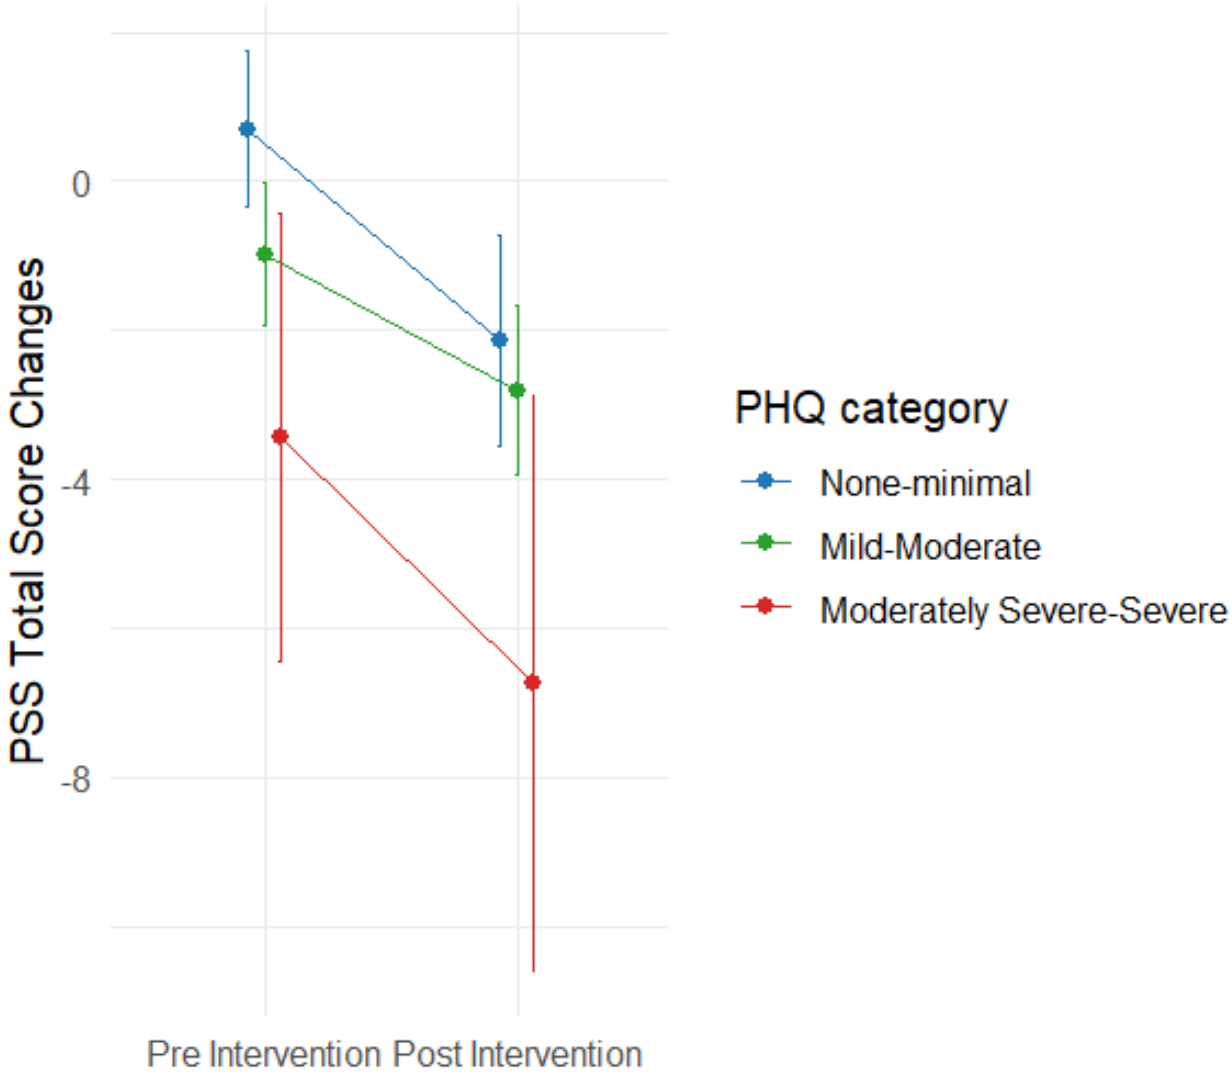

Figure 1. Changes in perceived stress using the 10-item Perceived Stress Scale (PSS-10) by professional category. Error bars indicate 95% CI.

Baseline depressive symptoms significantly moderated the intervention effect on perceived stress (B=−0.22, SE 0.08; *P*=.004). Higher baseline depression symptom scores were associated with greater reductions in perceived stress following the intervention. Further details of these analyses are presented in Table 2. Figure 2 illustrates the reductions in perceived stress during the preintervention and postintervention periods across 3 groups defined by baseline depressive symptom severity.

XSL•FO
RenderX

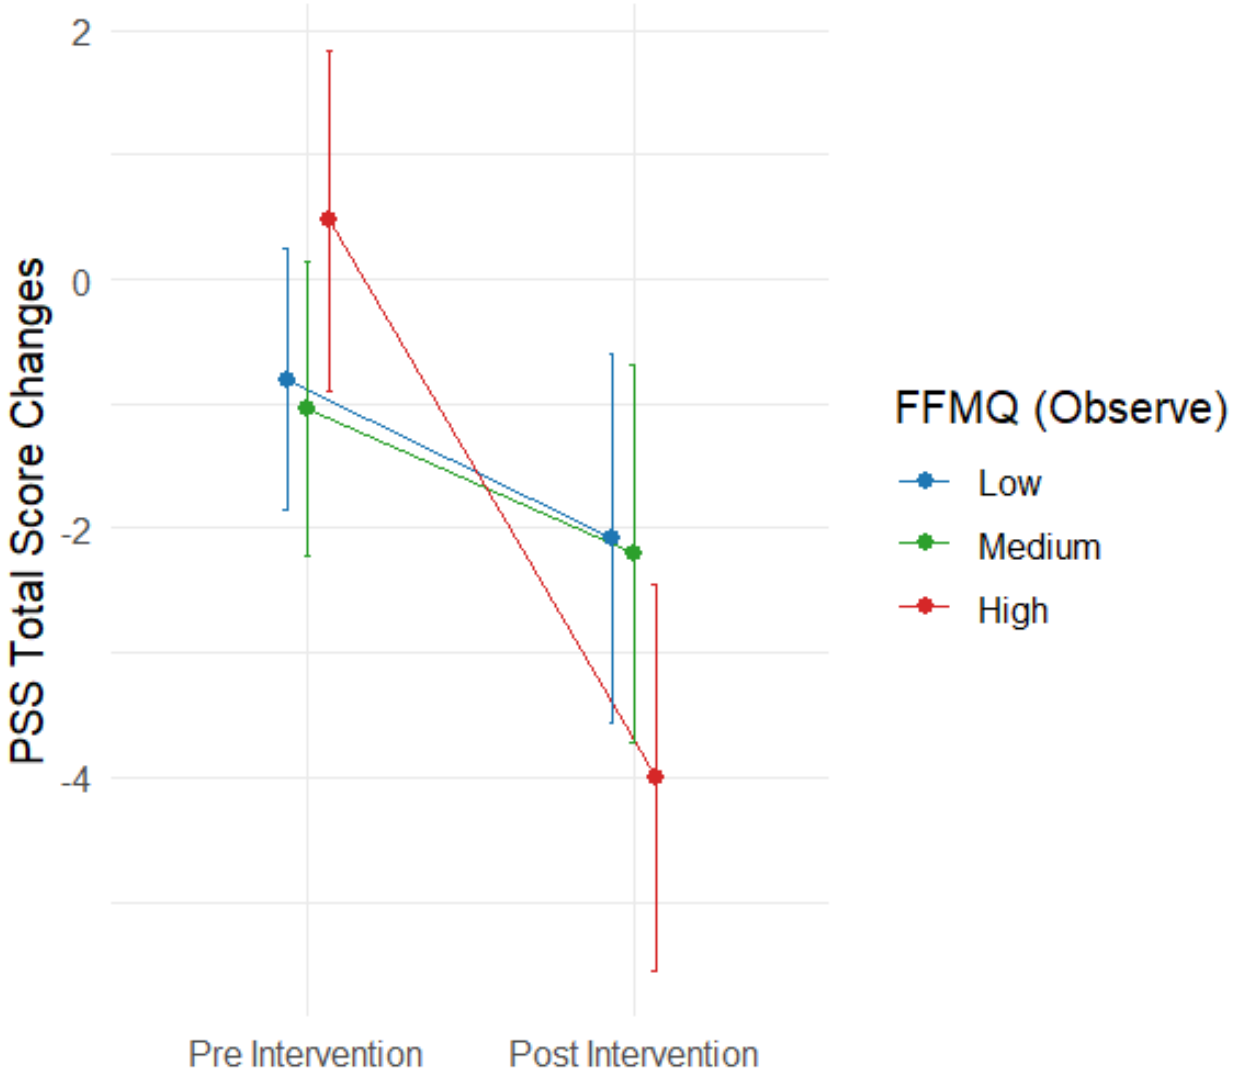

Figure 2. Changes in perceived stress using the 10-item Perceived Stress Scale (PSS-10) before and after the intervention by 9-item Patient Health Questionnaire (PHQ-9) depression severity category. None-minimal (0 - 4 score), mild-moderate (5 - 14 score), and moderately severe to severe depression (15 - 27 score). Error bars indicate 95% CI.

Additionally, the observing facet of mindfulness (FFMQ-15) also showed a significant moderation effect (B=−0.86, SE 0.41; *P*=.04). Health care professionals with higher baseline levels of mindful observation exhibited a more favorable response to the intervention. Further details of these analyses are presented in Table 2. Figure 3 illustrates the reductions in perceived stress during the preintervention and postintervention periods across 3 groups defined by baseline levels of the observing facet (low, medium, and high).

XSL•FO
RenderX

Figure 3. Changes in perceived stress using the 10-item Perceived Stress Scale (PSS-10) by levels of the 15-item Five Facet Mindfulness Questionnaire (FFMQ-15) observing facet. Low, medium, and high FFMQ—observing groups are defined using baseline tertiles. Error bars indicate 95% CI.

The results of the multivariate analysis are presented in Multimedia Appendix 1 and confirm the findings obtained in the univariate models. The moderating effects of baseline depressive symptoms (PHQ-9), nursing occupation, and the observing facet of mindfulness (FFMQ-15) on the effectiveness of the program remained statistically significant. In the multivariate model, these variables continued to play a significant moderating role in the reduction of perceived stress, whereas the remaining sociodemographic and occupational factors did not reach statistical significance.

In addition, the role of program adherence and the temporal sequence of the stepped-wedge design was explored. In the adjusted mixed-effects models, completing the program was not significantly associated with changes in perceived stress (B=−0.65, SE ##; *P*=.33), and no significant interaction was observed between the experimental condition and program completion (B=−0.99, SE 0.78; *P*=.20). Similarly, the temporal sequence of intervention implementation was not significantly associated with changes in perceived stress (B=−0.45, SE ##; *P*=.25) and did not moderate the intervention effect (B=0.61, SE ##; *P*=.19).

Discussion

Principal Findings

The present study explored individual, occupational, and psychological characteristics that may be associated with differential responses to the digital MINDxYOU program in reducing perceived stress among health care professionals. The findings suggest that baseline depressive symptoms, nursing occupation, and the observing facet of mindfulness may be potential moderators of intervention response. Although these results should be interpreted cautiously, they may provide preliminary insights into the characteristics of participants who could benefit most from this type of digital intervention. In this sense, the findings may contribute to ongoing efforts to develop more personalized and context-sensitive digital mental health programs for health care professionals.

First, the most robust finding of this study was the moderating role of baseline depressive symptoms. Participants with higher levels of depressive symptomatology at baseline benefited more from the intervention, showing larger reductions in perceived stress. This aligns with previous findings from an

XSL•FO
RenderX

internet-delivered mindfulness-based cognitive therapy study [40], in which more severe baseline depression predicted greater posttreatment improvement in anxiety among cancer survivors. Although further research is needed, this suggests that individuals with greater initial distress may benefit more from online mindfulness-based interventions. This finding is consistent with the literature describing a bidirectional relationship between stress and depression, in which chronic stress acts as both a precipitating and a maintaining factor of depression, while depressive symptoms increase threat perception and reduce coping resources [41]. From this perspective, it is plausible that an intervention based on acceptance and commitment principles and on mindfulness, both of which have demonstrated efficacy in reducing depressive symptoms, may be particularly beneficial in this subgroup [42,43]. These interventions promote acceptance of internal experiences, psychological flexibility, and self-compassion, processes that counteract the cognitive mechanisms underlying depression, such as rumination and experiential avoidance [44]. Thus, participants with more severe depressive symptoms may have benefited more from acquiring adaptive coping and self-compassion strategies targeting processes common to both stress and depression. These findings suggest the potential usefulness of MINDxYOU for health care professionals with greater emotional vulnerability.

Second, professional occupation showed a significant moderating effect. The results indicated that the magnitude of change in perceived stress differed across professional groups, with nursing staff showing greater reductions after the intervention than physicians and other health care professionals. These findings should be interpreted cautiously, as the present analyses do not establish the mechanisms underlying these differences. Nevertheless, professional roles in health care may involve distinct emotional, organizational, and caregiving demands, which could influence how participants engage with and respond to stress-reduction interventions [2,6]. These findings highlight the importance of adapting the content and support structure of digital interventions according to the specific emotional demands associated with different health care roles.

Finally, the observing facet of mindfulness appeared to moderate the intervention effect, suggesting that observing may be associated with differences in response to the program. Previous evidence has shown that mindfulness facets may have differential associations with stress and anxiety responses: whereas acceptance-related facets were associated with lower subjective and cortisol stress reactivity, monitoring-related facets such as observing were associated with higher cortisol reactivity and anxious arousal [45,46]. This result may also complement previous mediation analyses of the MINDxYOU trial [12] that identified resilience and the describing and nonreactivity facets of mindfulness as potential mechanisms of change. Existing evidence suggests that mindfulness-related processes may operate differently depending on the clinical outcome, context, and level of practice, with some studies identifying emotional regulation processes as potential mechanisms linking mindfulness to anxiety and depression, while others show that increases in mindfulness facets may mediate the association between formal practice and improvements in stress, symptoms, and well-being [47,48]. However, evidence regarding the moderating role of the observing facet remains limited, and the present findings should therefore be considered preliminary. Future studies are needed to clarify whether baseline mindful observation contributes to differential responses in digital mindfulness-based interventions.

The digital format of the intervention may facilitate the implementation of personalization strategies in real-world health care settings. These findings are consistent with the idea that mindfulness-based and third-wave digital interventions may not be uniformly effective across all users and that their impact may vary according to psychological and contextual factors. From an applied perspective, this knowledge may inform the development of more personalized digital mental health programs, in which the level of guidance, support, or sequencing of content could be adapted to the user's baseline profile [8]. Future studies should further investigate dynamic personalization mechanisms, integrating digital indicators of progress and hybrid clinical support to maximize the effectiveness of such interventions and enhance their real-world applicability in high-demand health care environments.

Limitations

This study has several limitations. Although the stepped-wedge design and the use of mixed-effects models allow partial control of time-related effects, the influence of unmeasured variables cannot be ruled out. In addition, the sample consisted predominantly of women health care professionals working in the public sector, which may limit the generalizability of the findings to other professional or health care contexts. Furthermore, the use of self-report measures may introduce potential biases, such as social desirability or recall bias. Future studies should incorporate physiological indicators and objective measures of program use to provide a more comprehensive assessment of intervention effects. Additionally, the relatively large number of moderators that were examined increases the possibility of a type I error. Therefore, the findings should be interpreted cautiously and considered exploratory and hypothesis-generating until replicated in future confirmatory studies specifically designed to evaluate moderation effects. Finally, interactions between moderators and patterns of digital adherence were not examined. These aspects could be explored in future research using adaptive and personalized intervention models, which may help optimize the personalization and effectiveness of digital mental health interventions for health care professionals.

Conclusions

The present study provides preliminary evidence that baseline psychological and occupational characteristics may influence responses to the MINDxYOU intervention among health care professionals. Higher depressive symptom scores, nursing occupation, and greater mindful observation were associated with larger reductions in perceived stress. These exploratory findings support the importance of considering individual characteristics when developing personalized digital mental health interventions.

Abstract

Background: Assistive robots have been proposed to support nursing work by offloading routine, logistical, and physically demanding tasks. However, existing research has largely focused on postimplementation acceptance or usability, with fewer studies examining how nurses conceptualize assistive robots before routine deployment, particularly in settings where exposure remains limited.

Objective: This study aimed to explore inpatient nurses' anticipatory perspectives on assistive robots and to examine how perceived benefits, concerns, and implementation conditions are constructed at the preimplementation stage.

Methods: A qualitative descriptive study was conducted using semistructured, face-to-face interviews with 16 registered nurses aged 21 to 32 years from 4 general medical wards in a public tertiary hospital in Singapore. At the time of data collection, assistive robots had not been routinely implemented; participants' exposure was limited to pilots, demonstrations, and indirect sources. Interview transcripts were analyzed using reflexive thematic analysis.

Results: Participants' accounts reflected anticipatory acceptance characterized by cautious optimism regarding the potential of assistive robots to support nursing work, alongside concurrent concerns about safety, professional identity, relational care, and implementation feasibility. Four themes were developed: anticipatory optimism shaped by indirect exposure; negotiating uncertainty, safety, and professional boundaries; imagining assistive robots as workload and workflow support; and conditions for responsible implementation. Concerns centered on professional identity, patient safety, ethical boundaries, loss of human touch, technical reliability, cost-effectiveness, and organizational feasibility. Participants viewed assistive robots as acceptable only if they were integrated into nursing workflows, preserved clinical judgment and relational care, and were supported by training, technical infrastructure, leadership commitment, and clear governance.

Conclusions: Nurses' anticipatory perspectives suggest that acceptance of assistive robots depends not only on perceived usefulness, but also on alignment with professional values, patient safety, relational care, and organizational readiness. Early nurse involvement, human-centered implementation, structured training, and clear governance are needed to ensure that assistive robots augment rather than undermine nursing practice.

Introduction

Assistive Robots and Their Emergence in Health Care

Assistive robots are increasingly positioned within the broader category of service assistive robots. Service assistive robots are commonly defined as assistive robots for personal or professional use that perform useful tasks for humans or equipment, excluding industrial automation applications [1]. In health care, assistive robots have been applied in multiple areas, including rehabilitation, patient mobility support, logistics, medication or supply delivery, socially assistive companionship, monitoring, and patient-facing support functions [2-6].

Interest in assistive robots has grown in response to workforce shortages, aging populations, infection-control demands, and pressure to improve productivity in health care systems [7-9]. Developments in sensor technology, AI, autonomous navigation, and human-robot interaction have expanded the potential functions of assistive robots beyond fixed repetitive tasks toward more adaptive forms of clinical and social support [2-4]. These capabilities not only make assistive robots potentially useful in care environments but also raise questions about safety,

XSL•FO
RenderX

accountability, workflow integration, and the boundaries of human-centered care [4,10,11].

During the COVID-19 pandemic, socially assistive robots were deployed in some care settings to support symptom screening and exposure assessment, illustrating one way assistive robots were used to reduce infection-related contact while maintaining service delivery [12,13]. However, pandemic-related deployments also highlighted that assistive robots must be evaluated not only for technical feasibility but also for acceptability, workflow fit, and their effects on human interaction [12,13].

Within nursing contexts, the term "assistive robots" refers to robots designed to support care through routine, physical, logistical, automated, or interactive functions. These include assistive robots and automated devices used in nurses' work, physically assistive technologies, and socially assistive robots intended to support interaction, engagement, or care delivery [4-6,10]. By reducing physical strain and repetitive workloads, assistive robots may help support nursing work and preserve time for patient-centered care [4,5,10]. However, their introduction into nursing practice is not merely a technical intervention. It may reshape task ownership, professional responsibility, nurse-patient interaction, and perceptions of what constitutes appropriate care [4,10,11].

Technology Acceptance and Preimplementation Perspectives

Technology acceptance research provides a useful starting point for understanding how health professionals respond to emerging technologies. The Technology Acceptance Model (TAM) and its extensions, including the Unified Theory of Acceptance and Use of Technology (UTAUT), emphasize constructs such as perceived usefulness, perceived ease of use, social influence, facilitating conditions, and intention to use [14,15]. In robot acceptance research, the Almere Model further adapts technology acceptance concepts for assistive and socially assistive robots by incorporating constructs such as trust, anxiety, social presence, perceived enjoyment, and perceived sociability [16].

However, acceptance is not formed solely through direct use. In preimplementation contexts, health professionals may construct expectations through demonstrations, workplace discourse, media narratives, peer accounts, or limited observational exposure. These anticipatory judgments can influence whether a technology is perceived as useful, safe, legitimate, or compatible with professional values before it becomes part of routine practice [15-18].

In this study, these anticipatory judgments are conceptualized as *anticipatory acceptance*, referring to nurses' prospective evaluation of whether assistive robots are likely to be useful, safe, appropriate, and compatible with nursing practice before routine implementation occurs. Unlike postimplementation technology acceptance, which develops through direct interaction and accumulated user experience, anticipatory acceptance is informed by indirect exposure and expectations about future clinical practice. It is also distinct from organizational readiness, which reflects preparedness for implementation, and from general attitudes toward technology, which do not necessarily consider how an innovation may be integrated into everyday nursing work. By focusing on anticipatory acceptance, this study seeks to understand how nurses begin to negotiate the potential role of assistive robots in nursing practice before assistive robots become part of routine care.

In nursing, the preimplementation stage is especially important because assistive robots enter a practice environment where clinical judgment, embodied care, emotional labor, accountability, and workflow coordination are central [4,10,11]. Nurses' early interpretations may therefore shape not only their willingness to use assistive robots but also how they define appropriate task delegation, human oversight, and acceptable limits of automation.

Nurses' Acceptance of Assistive Robots

Existing studies suggest that nurses and care professionals often hold cautiously positive attitudes toward assistive robots [6,13,17-20]. Positive perceptions are commonly associated with the potential to reduce physical strain, support routine or repetitive tasks, improve workflow efficiency, and alleviate aspects of the nursing workload [4-6,10]. At the same time, concerns persist regarding technical reliability, patient safety, the loss of human touch, privacy, ethical accountability, costs, and potential effects on employment or professional identity [6,10,11,13,17-20].

Acceptance also appears to be shaped by task type and perceived fit with professional values. Assistive robots tend to be viewed as more acceptable for logistical, repetitive, or physically demanding tasks than for emotionally sensitive, relational, or judgment-intensive aspects of care [5,6,13,17,20]. This distinction is important in nursing because care work is not only defined by task completion but also by surveillance, interpretation, communication, and relational presence [10,11].

The work by Turja et al [17,18] is particularly relevant because it moves beyond general technology acceptance to examine care workers' readiness for robotization and their intention to use assistive robots in professional contexts. Their Robot Acceptance Model for Care (RAM-care) highlights that robot acceptance is shaped not only by perceived usefulness but also by social influence, attitudes, and whether robot use is perceived as consistent with personal and professional values [17]. This suggests that acceptance of assistive robots in nursing cannot be understood as an individual preference alone; it is also shaped by organizational expectations, task legitimacy, perceived value alignment, and the wider social meaning of robotized care [17,18].

Despite this growing literature, important gaps remain. Much of the existing evidence is quantitative, cross-sectional, or based on attitude and acceptance measures [17-20]. These studies are useful for identifying predictors of acceptance, but they provide limited insight into how nurses interpret, negotiate, and anticipate the implications of assistive robots before routine implementation. Existing qualitative work has begun to examine nurses' experiences and perceptions of socially assistive technologies, including during COVID-19-related deployments

[13], but fewer studies have explored anticipatory perspectives in acute inpatient settings where assistive robots remain emergent rather than embedded. This limits understanding of how nurses anticipate the ethical, professional, operational, and economic implications of robotic systems before they become part of everyday clinical workflows.

Conceptual and Ethical Considerations in Nursing Practice

The integration of assistive robots into nursing practice raises conceptual and ethical questions about professional identity, task ownership, accountability, and the boundaries of relational care [4,10,11]. Although these technologies are often framed as supportive tools, their introduction may reshape how nursing work is organized, experienced, and valued.

Existing literature reflects these tensions. Some nurses and care professionals view assistive robots positively, emphasizing their potential to alleviate workload and support care delivery, whereas others express concerns about technical reliability, reduced human interactions, ethical trade-offs, and accountability when care is mediated by machines [10,11,13,16,19]. Practical barriers, including high acquisition and maintenance costs, technical complexity, maintenance requirements, and limited institutional support infrastructure, may further complicate adoption [8,10]. Hesitancy may also reflect anxieties about job displacement or perceived misalignment between robotic functions and core nursing values [6,10,11,17,18].

Local Context and Study Aim

Nurses play a central role in inpatient care delivery and are directly affected by how assistive robots may reshape workflows, task boundaries, and clinical responsibility. At the same time, the nursing workforce faces sustained pressure from staff turnover, aging populations with complex needs, and increasing care demands [7,8]. Assistive robots and other automated technologies have been proposed as potential tools to support nursing work and care delivery [4,5,10,21], yet successful integration depends heavily on nurses' engagement, trust, and sense-making [6,13,17-19].

As primary users and workflow mediators, nurses' involvement in the design, implementation, and evaluation of assistive robots is critical, as they hold firsthand knowledge of clinical demands, patient needs, workflow constraints, and contextual risks [4,5]. Prior research suggests that attitudes toward assistive robots are shaped by familiarity, perceived usefulness, perceived ease of use, and prior or indirect exposure [6,16-20]. However, much of the existing evidence relies on quantitative instruments such as robot attitude or acceptance scales [17-20]. These approaches are useful for measuring acceptance-related constructs but provide limited insight into how nurses interpret, negotiate, and anticipate the implications of assistive robots in everyday inpatient practice.

In the study hospital, assistive robots had been piloted on a limited basis, but were not routinely implemented in inpatient nursing care. Local exposure was primarily limited to demonstrations, institutional briefings, and small-scale pilots involving nonclinical robotic functions, such as logistics support (eg, supply delivery) and task-support activities, such as providing on-demand audio-visual support for patient orientation and educational activities. This created an opportunity to examine how nurses formed anticipatory perspectives in the absence of sustained hands-on experience with assistive robots. This study, therefore, aimed to explore how inpatient nurses conceptualized, interpreted, and anticipated the use of assistive robots in clinical practice, including their perceived benefits, concerns, ethical boundaries, and conditions influencing future adoption.

Methods

Study Design

This study used a qualitative descriptive design to explore inpatient nurses' anticipatory perspectives on assistive robots in clinical care. This design was appropriate because the study sought to generate a practice-near understanding of their expectations, concerns, and perceived implementation conditions in a context where routine exposure to assistive robots was limited. Interview data were analyzed using reflexive thematic analysis.

Participants and Setting

A convenience sampling strategy was used to recruit registered nurses from 4 general medical inpatient wards in a public tertiary hospital in Singapore. These wards were selected because they were the clinical areas where small-scale pilots, demonstrations, and informal exposure to assistive robots had occurred. At the time of data collection, assistive robots had not been routinely implemented in inpatient nursing care at the study site. Nurses' exposure was therefore largely indirect and was limited primarily to small-scale pilots and demonstrations involving nonclinical robotic functions, particularly logistics and task-support activities, together with institutional briefings, educational videos, and informal discussions among colleagues. None of these robotic systems were routinely integrated into bedside nursing practice, and participants did not report sustained hands-on experience using assistive robots during their daily clinical work. Consequently, the study explored anticipatory perspectives informed by limited local exposure rather than reflections based on routine clinical use.

Eligible participants were registered nurses working in the selected wards who had direct experience with inpatient nursing workflows. Potential participants were identified through ward rosters and approached by members of the research team during nonclinical hours. Convenience sampling was used because the pool of nurses with contextual exposure to assistive-robot pilots was limited.

The possibility of sampling bias cannot be excluded. Nurses who participated in the interviews could have held stronger preconceptions about assistive robots compared to those who declined. In addition, the sample comprised mainly early-career nurses, which may have shaped the concerns and expectations, and professional identity negotiations reflected in the findings. Nonetheless, the findings may be transferable to similar acute inpatient settings where assistive robots are at an early or anticipatory stage of implementation.

XSL•FO
RenderX

Researcher Positionality and Reflexivity

The research team comprised registered nurses with at least 5 years of clinical experience in acute inpatient care and prior experience conducting qualitative research. None of the team members had direct hands-on responsibility for implementing assistive robots in clinical practice. This positioned the team as clinically informed about inpatient nursing work but not directly invested in any specific implementation outcome.

Interviews were conducted by 2 members of the research team, TLTC and MWT, both registered nurses who did not hold supervisory, managerial, or appraisal responsibilities for the participants. This helped reduce potential power imbalances during recruitment and interviews.

The researchers recognized that their nursing backgrounds could sensitize them to issues such as workload, patient safety, professional accountability, and relational care, while also potentially shaping how participants' accounts were interpreted. At the same time, the shared professional background between interviewers and participants was considered likely to facilitate rapport and enable discussion of workplace realities using familiar clinical language. The researchers remained mindful; however, that this insider position could also encourage implicit assumptions about nursing practice or shared understandings that might otherwise have been explored more explicitly during interviews. Interviewers therefore used follow-up and clarifying questions to encourage participants to elaborate on their perspectives rather than assuming shared meanings.

To support reflexivity, the team held regular analytic discussions throughout data collection and analysis. These discussions examined assumptions, considered alternative interpretations, and avoided framing participants' views as either simple resistance to innovation or uncritical acceptance of technology.

Procedures

Potential participants were approached in-person by members of the research team during nonclinical hours and provided with an information sheet detailing the study aims and procedures. They were given time to consider their participation. Of the 20 nurses approached, 16 consented to participate, while 4 declined due to scheduling constraints or lack of interest. Written informed consent was obtained from all participants.

A pilot interview was conducted with one registered nurse from a general medical inpatient ward within the same hospital to assess the clarity, flow, and relevance of the interview questions. The pilot also provided the interviewers with an opportunity to familiarize themselves with the interview process and refine their interviewing approach. No substantive revisions to the interview guide were required following the pilot interview, and the same interview guide was subsequently used for all participants. Consistent with qualitative research practice, the pilot interview was not included in the final analysis.

Semistructured, face-to-face interviews were conducted with the 16 participants between October 2023 and June 2024. Interviews took place in a private room within the hospital to ensure confidentiality and minimize interruptions. Both interviewers received the same training to ensure consistency in interview conduct and reduce variation in interview style.

At the start of each interview, participants were provided with a brief description of assistive robots to establish a common frame of reference. Examples included nursing-care assistive robots (eg, medication delivery and patient transport), physically assistive robots (eg, patient lifting and mobility support), and socially assistive robots (eg, companionship and cognitive support). These examples were presented solely to ensure a consistent understanding of the terminology and did not imply that such assistive robots were routinely available at the study hospital. Participants were subsequently invited to describe what they understood by the term "assistive robots" and to reflect on how such technologies might influence nursing practice based on their own observations, indirect exposure, or personal interpretations.

The interview guide explored participants' perceptions of assistive robots, including perceived benefits, concerns, ethical considerations, and expectations for implementation. Open-ended questions were used, and participants were encouraged to provide concrete examples. Interviews lasted between 60 and 90 minutes. All interviews were audio-recorded with participants' permission and transcribed verbatim. Identifying information was removed from transcripts to protect participant anonymity.

Data Adequacy

Recruitment and data collection occurred concurrently with preliminary analysis. Data adequacy was assessed iteratively during data collection, with attention to code saturation and thematic sufficiency rather than to exhaustive meaning saturation. After approximately 14 interviews, no substantially new codes were identified across the main topic areas, and participants' accounts showed repeated patterns regarding perceived benefits, safety concerns, professional boundaries, and implementation conditions. Two additional interviews were conducted to assess the stability of the developing thematic structure. The final sample of 16 participants was judged sufficient for the study aim, design, and focused clinical context, while recognizing that findings remain contextually situated rather than statistically generalizable.

Data Analysis

Interview transcripts were analyzed using reflexive thematic analysis as described by Braun and Clarke [22]. The analysis involved iterative phases of familiarization, initial coding, theme development, reviewing, and defining and naming themes.

Consistent with the qualitative descriptive design, the analysis aimed to provide a clinically grounded account of nurses' perspectives while recognizing that theme development involved active interpretation by the researchers. Themes, therefore, moved beyond simple topic summaries to capture patterns of shared meaning across participants' accounts, while remaining closely anchored in their descriptions of anticipated experiences with assistive robots.

Initial coding was conducted by 1 author (TCLT) to generate codes that captured patterns of meaning relevant to the study

XSL•FO
RenderX

aims. Coding was conducted primarily inductively, while remaining sensitized to concepts identified in prior literature, including perceived usefulness, workflow fit, patient safety, ethical concerns, and professional boundaries. Codes were revised as the analysis progressed and as new interpretations emerged from repeated engagement with the data.

Theme development was interpretive and reflexive rather than based on consensus coding. Provisional themes were generated through repeated engagement with coded data extracts, the full dataset, and emerging analytic interpretations. Regular analytic discussions were held among the research team to interrogate assumptions, explore alternative explanations, and refine the coherence and distinctiveness of themes. These discussions were used to support reflexive interpretation rather than to achieve intercoder agreement.

Themes were finalized based on coherence, distinctiveness, and explanatory relevance to the research questions. An audit trail documenting coding decisions, theme development, and analytic refinements was maintained throughout the process. Data were managed using Microsoft Excel to support systematic coding and documentation.

The study is reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) Checklist 1 [23].

Ethical Considerations

The study was conducted in accordance with the ethical principles outlined in the Declaration of Helsinki. Ethical approval was obtained from the National Healthcare Group Domain Specific Review Board (reference number: 2023/00679). Written informed consent was obtained from all participants prior to the interviews.

Participants were informed that participation was voluntary and that refusal or withdrawal would not result in any adverse consequences, including effects on employment status or performance appraisals. Participants were advised that they had the right to decline to answer any interview questions and to withdraw from the study at any time prior to data analysis.

No reimbursement or incentives were provided for study participation. Participant confidentiality and anonymity were ensured throughout the study. Audio recordings and interview transcripts were stored securely, with access limited to members of the research team. All personally identifiable information was removed during transcription and data analysis. Patients and/or the public were not involved in the design, conduct, reporting, or dissemination plans for this research.

Results

Participant Characteristics and Overview of Themes

Demographic characteristics of the 16 participants are presented in Table 1. No participants withdrew after providing informed consent. Participants ranged in age from 21 to 32 years, with a mean age of 26 (SD 2.94) years. The majority of participants were Singaporean citizens or permanent residents (n=11). Five participants were foreign nurses: 4 were from Malaysia and 1 was from Myanmar. The mean duration of professional nursing experience was 34 (SD 2.05) months.

20 - 25	7 (43.8)
26 - 30	7 (43.8)
31 - 35	2 (12.5)
Designation	
Staff nurse	10 (62.5)
Senior staff nurse	6 (37.5)
Professional nursing experience (y)	
<1	4 (25)
1 - 5	11 (68.8)
6 - 10	1 (6.3)
Highest nursing education level	
Polytechnic diploma	8 (50)
University degree	8 (50)
Nationality or residency status	
Singapore citizen or permanent resident	11 (68.8)
Foreign nurse: Malaysia	4 (25)
Foreign nurse: Myanmar	1 (6.3)

Four themes were developed from the analysis: (1) anticipatory optimism shaped by indirect exposure; (2) negotiating uncertainty, safety, and professional boundaries; (3) imagining assistive robots as workload and workflow support; and (4) conditions for responsible implementation. Table 2 summarizes the relationship between initial codes, subthemes, and overarching themes. The thematic structure illustrates that participants' perspectives were not formed through routine use of assistive robots, but through anticipatory sense-making shaped by limited exposure, imagined use, perceived usefulness, safety concerns, professional boundaries, and implementation conditions.

Table . Development of themes from initial codes to subthemes and overarching themes.

Initial codes or analytic ideas	Subthemes	Overarching themes
Curiosity, demonstrations, media exposure, imagined use, and cautious optimism	Indirect exposure, imagined usefulness, and conditional openness	Anticipatory optimism shaped by indirect exposure
Malfunction, overreliance, patient safety, job displacement, human touch, counseling discomfort, and cost concerns	Safety and reliability, professional role boundaries, relational care limits, and organizational feasibility	Negotiating uncertainty, safety, and professional boundaries
Lifting support, patient turning, transport, basic requests, information retrieval, workload reduction, and staff retention	Physical workload support, routine task support, workflow responsiveness, and organizational benefits	Imagining assistive robots as workload and workflow support
Training, hands-on practice, protected time, phased pilots, technical support, leadership, and champions	Competency development, gradual implementation, support infrastructure, and leadership and buy-in	Conditions for responsible implementation

Table 2 illustrates how participants' anticipatory perspectives on assistive robots were shaped by perceived usefulness, safety concerns, professional boundaries, workload expectations, and implementation conditions.

Theme 1: Anticipatory Optimism Shaped by Indirect Exposure

Participants expressed curiosity and cautious optimism toward assistive robots as potential tools to support nursing work and alleviate routine workload. Although most nurses had limited

XSL•FO
RenderX

direct exposure to assistive robots in health care, they articulated generally positive expectations about their future role in nursing practice, particularly in relation to physically demanding, repetitive, or time-consuming tasks.

Participants' perspectives were shaped largely by anticipatory and indirect exposure rather than sustained hands-on use. They drew on demonstrations, informal observations, media portrayals, peer discussions, and imagined future scenarios to consider how assistive robots might function in clinical practice. These indirect forms of exposure contributed to both interest and caution, suggesting that nurses began forming views about assistive robots before routine implementation. One participant stated, "But hopefully in the future I have a robot to help us to turn the patient, take orders from the patient… and engage the patient as well" (P13).

Some participants envisioned assistive robots as intelligent support tools that could enhance efficiency at the point of care by facilitating rapid access to information:

> *If the robot… can act like a computer, like Siri… then it can show me immediately. Don't need to search.* [P10]

Despite this openness, participants' optimism was tempered by uncertainty. Nurses emphasized the need for evidence of effectiveness, reliability, and sustainability before fully trusting assistive robots in clinical care. Concerns were raised about the overreliance on technology and the potential consequences of system failure in patient care settings:

> *It's 50–50… it would be really helpful if you can rely on it. But sometimes I'm worried that we might over rely on it.* [P14]

Others questioned whether assistive robots would genuinely reduce workload or instead introduce additional responsibilities for nurses, particularly if the technology requires ongoing supervision or troubleshooting. One participant stated, "Will it be a helping hand or extra workload for us?" (P13).

Overall, nurses' accounts reflected openness to innovation alongside a cautious appraisal. Their optimism was not unconditional but grounded in practical concerns about whether assistive robots would be reliable, useful, and compatible with everyday nursing work.

Theme 2: Negotiating Uncertainty, Safety, and Professional Boundaries

Participants articulated several uncertainties about the integration of assistive robots into nursing practice. A prominent concern was related to job security and role displacement. Some nurses worried that assistive robots might encroach on aspects of nursing work, while simultaneously emphasizing that core nursing functions involving human judgment, accountability, and emotional engagement could not be replicated by machines. One participant stated, "I hope we can use it to relieve the workload, but not totally relying on it… otherwise they would take over our role" (P14).

Concerns about technical reliability were also prominent. Participants highlighted the risk of system malfunction and stressed the importance of maintaining human oversight, particularly in situations where patient safety could be affected. One participant stated, "Assistive robots can malfunction… we as humans should know how to override it and take over" (P07).

Several participants cautioned against excessive reliance on assistive robots, emphasizing that patient safety ultimately remains dependent on nurses' situational awareness, monitoring, and ability to intervene when needed. One participant stated, "You still need to check the robot because it is about patient safety" (P01).

Participants consistently raised concerns about the potential loss of human touch in nursing care. Emotional support, physical reassurance, and empathetic communication were described as fundamental aspects of nursing that should not be fully delegated to assistive robots. Importantly, nurses did not frame these concerns as a rejection of assistive robots, but rather as boundary-setting around the relational and emotional dimensions of care. One participant stated, "Touch therapy is one aspect that can't be replaced by assistive robots" (P14).

Some participants expressed discomfort with the idea of assistive robots engaging in emotionally sensitive interactions, such as counseling or responding to patient distress, suggesting limits to the appropriateness of robotic involvement in relational care. One participant stated, "If you have a robot coming to give you counseling, that's a bit weird… they probably need a human" (P06).

Beyond clinical and ethical considerations, participants framed assistive robots in explicitly economic terms. Bedside nurses-raised concerns about cost-effectiveness, maintenance burden, and return on investment, reflecting a pragmatic awareness of organizational resource constraints and sustainability. One participant stated, "If it's very expensive and doing very minimal work, then definitely not sustainable" (P06).

Together, these uncertainties show that participants' concerns were multidimensional. They involved not only whether assistive robots would work technically but also whether they would preserve safety, professional identity, ethical boundaries, organizational feasibility, and relational care.

Theme 3: Imagining Assistive Robots for Workload and Workflow Support

Despite these uncertainties, participants identified several ways in which assistive robots could positively contribute to nursing practice. Many viewed assistive robots as potential tools for increasing nursing capacity by taking over selected routine or physically demanding tasks. This was perceived as a way to reduce physical strain, conserve cognitive resources, and allow nurses to focus on more complex clinical responsibilities. One participant stated, "It can help reserve our brain power for more critical things" (P08).

Participants anticipated benefits for physically demanding activities, such as patient lifting and transport, which they believed would reduce occupational strain and help prevent injury. One participant stated, "If there is a robot that can help lift a heavy patient, it helps prevent back pain" (P09).

XSL•FO
RenderX

Some participants also linked assistive robots to improved responsiveness to patients' basic needs. They suggested that assistive robots could help reduce waiting times for simple requests, such as obtaining water or retrieving items, thereby improving the patient experience while allowing nurses to attend to more urgent clinical priorities. One participant stated, "If the robot can help take simple things like water immediately, then the patient will be happy" (P10).

At the organizational level, participants perceived that the use of assistive robots could reap potential operational benefits, including improved productivity, staff satisfaction, and retention. One participant stated, "The staff workload can be a bit lesser… then you can retain your staff" (P02).

Some nurses also noted that visible adoption of assistive robots could enhance the hospital's public image as innovative and technologically progressive. Importantly, participants consistently framed the benefits of assistive robots as contingent on their integration into nursing practice, emphasizing alignment with nursing workflows, the reduction rather than the addition of workload, preservation of clinical judgment, and the protection of relational care.

Theme 4: Conditions for Responsible Implementation

Participants emphasized that successful integration of assistive robots would depend on several implementation conditions. Structured and ongoing training was viewed as essential for building confidence and competence, with nurses highlighting the importance of hands-on learning, clear guidance, and opportunities to practice using the technology before being expected to incorporate it into routine care. One participant stated, "If I want to use this robot, I would really want to go for a training session first" (P13).

Protected training time during working hours was considered critical to prevent cognitive overload and ensure meaningful engagement. Participants were concerned that implementation would be less effective if training were added on top of the existing workload or delivered without sufficient opportunity for practice.

Participants also emphasized the importance of phased implementation through small-scale pilots. Gradual introduction was viewed as a way for nurses to assess reliability, understand the robot's functions, and build trust over time. One participant stated, "Give the staff some time to get used to how reliable the robot is" (P14).

Adequate technical support and rapid troubleshooting were identified as essential to prevent assistive robots from becoming additional burdens rather than supportive tools. One participant stated, "It's supposed to offload us, not add on" (P08).

Stakeholder buy-in was another key implementation condition. Participants highlighted the role of leadership support, clear communication, feedback mechanisms, and staff champions in encouraging adoption. One participant stated, "You just need a champion… then everybody will hop on to the idea" (P05).

At the same time, nurses acknowledged variability in receptivity to assistive robots, noting differences in comfort with technology among individuals. Participants suggested that tailored training, leadership engagement, and clear expectations may be required to support successful integration. Overall, participants viewed responsible implementation as requiring more than access to the technology itself. It depended on preparation, training, technical infrastructure, leadership support, and governance processes that ensured assistive robots were introduced as supportive tools rather than additional burdens.

Discussion

Principal Findings

This study explored inpatient nurses' anticipatory perspectives on assistive robots in a clinical context where such technologies had been piloted on a limited basis but were not routinely implemented. Participants' accounts reflected anticipatory acceptance characterized by cautious optimism regarding the potential of assistive robots to support nursing work, alongside concurrent concerns about safety, professional identity, relational care, and implementation feasibility.

The findings extend existing literature by demonstrating that nurses' views on assistive robots are formed before routine use through anticipatory sense-making. Participants' perspectives were shaped largely by indirect exposure, including demonstrations, peer discussions, and imagined future use. This preimplementation perspective is important because early interpretations may subsequently influence trust, acceptance, resistance, and implementation trajectories.

Importantly, nurses did not view assistive robots merely as technological devices. Instead, they assessed these technologies in relation to their potential impact on patient safety, professional responsibility, therapeutic relationships, clinical workflows, and the long-term sustainability of health care organizations. Their acceptance of assistive robots was, therefore, contingent upon the extent to which these technologies were perceived as supporting and enhancing, rather than substituting, professional nursing judgment and the relational aspects of care.

Anticipatory Acceptance Before Routine Implementation

Participants' cautious optimism is consistent with previous studies showing that nurses and other care professionals often view assistive robots positively when they are perceived to reduce physical workload, support routine tasks, and improve workflow efficiency [4-6,10]. Concerns relating to technical reliability, reduced human interaction, cost, and role displacement align with prior research on nurses' and care professionals' attitudes toward assistive robots in health and social care settings [6,13,17-20].

This study adds nuance by focusing on the preimplementation stage. TAMs such as the TAM and the UTAUT emphasize perceived usefulness, perceived ease of use, social influence, facilitating conditions, and intention to use as key determinants of acceptance [14,15]. The Almere model further highlights constructs such as trust, anxiety, perceived sociability, and enjoyment [16]. Building on these concepts, our findings suggest that anticipatory acceptance extends beyond conventional

XSL•FO
RenderX

technology assessments of usefulness and usability to include concerns about safety, professional boundaries, relational care, and potential consequences of implementation for everyday work (ie, whether the technology will add to or reduce work).

This finding is consistent with the work by Turja et al [17] which demonstrated that assistive robot acceptance is influenced by factors beyond technical utility. RAM-Care highlights that the intention to use assistive robots is shaped by attitudes, social influence, perceived usefulness, and value alignment, while research on care workers' readiness for robotization has identified psychological and sociodemographic influences on readiness and acceptance [18]. Our present study extends this literature by showing how nurses reason through these issues before routine implementation, particularly in an acute inpatient environment where assistive robots remain an emerging rather than an embedded technology.

Task Boundaries, Professional Identity, and Relational Care

Rather than rejecting assistive robots outright, participants appeared to define moral and professional boundaries around their use. Their accounts suggest that acceptance depended less on the technology itself than on whether its intended role aligned with nurses' expectations regarding appropriate task delegation, clinical judgment, accountability, and relational care. Concerns about "human touch" therefore reflect efforts to preserve aspects of nursing work regarded as fundamentally human, rather than resistance to technology. Viewed in this way, participants' concerns functioned as a form of boundary-setting through which nurses distinguished tasks that could appropriately be supported by robotic tools from those that should remain primarily human.

This interpretation aligns with the literature suggesting that assistive robots may support selected nursing tasks while also raising questions about the fundamentals of care, professional identity, and relational practice [4-6,10]. Archibald and Barnard [10] argue that assistive robots should be considered in relation to fundamental nursing care goals rather than being treated only as technological innovations. Ethical analyses of assistive robots in health care have also emphasized how robotic systems may alter responsibility, agency, and human interaction in care contexts [11].

Participants' view that assistive robots should augment rather than replace nursing work is also consistent with local policy directions that position technology as an enabler of care rather than a substitute for professional expertise [24]. Our study findings contribute a frontline perspective by illustrating how nurses define the acceptable limits of robotic assistance in relation to patient safety, accountability, and relational care.

Safety, Trust, and Human Oversight

Trust emerged as a governance issue rather than merely being an individual attitude. Participants' accounts suggest that confidence in assistive robots depends on organizational arrangements that ensure reliability, transparency, accountability, and appropriate human oversight. These concerns are consistent with the broader human factors literature on automation bias and complacency, where users may place excessive trust in automated systems or fail to detect errors despite their fallibility [25]. Recent health care–focused work similarly highlights automation bias as a risk associated with the increasing introduction of AI applications into clinical practice when failure modes, accountability, and user oversight are not adequately addressed [26].

For nursing practice, these concerns are especially important because patient safety depends on continuous surveillance, contextual judgment, and timely escalation. Participants not only framed assistive robots as autonomous replacements for nurses but also as tools that should operate under human supervision. This supports a governance approach in which assistive robots are introduced with clear task boundaries, escalation criteria, downtime procedures, incident-reporting mechanisms, maintenance responsibilities, and competency requirements.

The implication is that trust should not be treated as a matter of users' attitudes alone. Trust must be designed and governed. Nurses are more likely to view assistive robots as acceptable when systems are reliable, transparent in function, supported by technical infrastructure, and embedded within clear accountability arrangements.

Economic Reasoning and Organizational Readiness

A noteworthy finding was that frontline nurses incorporated organizational and economic considerations into their anticipatory evaluations of assistive robots. Participants questioned whether assistive robots would deliver sufficient benefits to justify investment, whether they could perform meaningful functions within existing workflows, and whether maintenance or troubleshooting would create additional workload. Although economic evaluation and return on investment are often assumed to be managerial concerns, our study findings suggest that frontline nurses also consider organizational sustainability when judging the value of emerging technologies.

This finding extends the literature on robot acceptance by demonstrating that nurses evaluate assistive robots not only through individual acceptance constructs but also through broader considerations such as perceived organizational value. Practical implementation barriers such as cost, technical complexity, and institutional support have similarly been identified in studies of robotic surgery and socially assistive robot implementation [27,28]. Our study's findings indicate that these considerations are also evident in nurses' own reasoning even before routine implementation.

The findings also align with implementation science perspectives that view technology adoption as a complex systems process rather than a simple user acceptance issue. The Non-Adoption, Abandonment, Scale-up, Spread and Sustainability (NASSS) framework highlights that adoption and sustainability of health technologies are influenced by the technology, value proposition, adopters, organizational context, wider systems, and adaptation over time [9]. Applying this lens, successful implementation of assistive robots in nursing would depend not only on whether nurses perceive assistive robots as useful but also on whether the organization can provide infrastructure, technical support,

XSL•FO
RenderX

workflow redesign, training, maintenance, and credible evidence of value.

Practical Implications

Our findings suggest that the implementation of assistive robots in inpatient nursing should follow a staged and governance-oriented approach.

First, organizations should conduct workflow mapping before procurement or implementation. This will allow organizations to identify tasks that are repetitive, physically demanding, time-consuming, or logistical, and distinguish them from tasks requiring clinical judgment, emotional support, complex communication, or relational presence. This approach may help ensure that assistive robots are introduced in ways that are most likely to complement, rather than disrupt, nursing work.

Second, implementation should begin with small-scale pilots before wider deployment. Pilot evaluation should assess not only technical performance but also the impact on nursing workload, patient safety, patient experience, staff trust, workflow integration and/or disruption, maintenance burden, and unintended consequences. This is especially important given participants' concerns that assistive robots could increase rather than reduce workload if poorly integrated.

Third, training should be structured, hands-on, and competency-based. Training should include technical operation, troubleshooting, escalation procedures, downtime management, infection prevention, patient communication, and the limits of robotic assistance. Protected training time may be necessary, as training delivered on top of the routine workload may reinforce perceptions that assistive robots add to the burden rather than reduce it.

Fourth, governance structures should clearly define accountability and support nurses' involvement throughout the implementation process. Organizations should define who is responsible for monitoring robot performance, responding to malfunctions, reporting incidents, maintaining equipment, reviewing safety data, and deciding when human intervention is required. These arrangements are essential to address participants' concerns about overreliance, malfunctions, and patient safety.

Fifth, there should be organizational support for nurses' involvement throughout the implementation stage. Nurses should be engaged early in design, procurement, pilot testing, and evaluation to help identify workflow mismatches, clarify appropriate task boundaries, and address concerns about professional identity and relational care. Nurse champions may support engagement, but champion-led adoption should be accompanied by leadership support, technical infrastructure, and feedback mechanisms.

Overall, implementation strategies should frame assistive robots as supervised tools that augment nursing work, rather than as substitutes for professional judgment or human interaction. Organizations should also establish predefined evaluation metrics to determine whether assistive robots achieve their intended clinical and organizational benefits. These measures may include nursing workload (eg, time spent on routine tasks), operational efficiency (eg, response times and task completion rates), patient safety (eg, robot-related incidents and downtime events), patient experience (eg, patient satisfaction and acceptability), workforce outcomes (eg, nurse satisfaction, perceived workload, and confidence in using assistive robots), and organizational outcomes (eg, robot use, maintenance burden, and service interruptions). Routine monitoring of these indicators would enable organizations to evaluate implementation effectiveness, identify unintended consequences, and refine deployment strategies over time.

Theoretical Implications

This study contributes to the technology acceptance and robot acceptance literature by foregrounding the anticipatory stage of acceptance. Existing models such as TAM, UTAUT, the Almere Model, and RAM-Care provide useful constructs for understanding perceived usefulness, ease of use, social influence, trust, anxiety, and intention to use [14-17]. The findings suggest that in inpatient nursing, anticipatory acceptance also involves professional and ethical reasoning. Nurses evaluated assistive robots in relation to patient safety, relational care, task legitimacy, accountability, workload implications, and organizational sustainability.

The study also contributes to the sociotechnical understanding of health care technology adoption. Participants evaluated assistive robots within broader clinical, organizational, and professional contexts rather than as isolated technological artifacts. Acceptance was shaped by anticipated interactions between technology and existing staffing pressures, workflow demands, patient needs, professional values, maintenance systems, and leadership support. Taken together, our findings support the view that the implementation of assistive robots represents a sociotechnical change in nursing work rather than simply the introduction of a new device.

Limitations

This study has several limitations. First, participants were recruited from 4 general medical inpatient wards in one public tertiary hospital in Singapore where assistive robots had been piloted on a limited basis but were not routinely embedded in practice. The findings therefore reflect anticipatory perspectives rather than experiences of sustained use. Nurses' views may change after direct and repeated interaction with assistive robots in routine care.

Second, convenience sampling may have introduced selection bias. Nurses with stronger views about assistive robots may have been more willing to participate than those who declined participation.

Third, the sample consisted mainly of early-career nurses, which may have shaped the emphasis on professional identity, role security, and confidence in managing emerging technologies. More experienced nurses, advanced practice nurses, and nurse leaders may place greater emphasis on clinical governance, service redesign, workflow integration, and organizational implementation considerations. Future studies should therefore include participants across different career stages and nursing roles.

XSL•FO
RenderX

Fourth, the study was conducted in a digitally enabled hospital context, which may limit transferability to settings with different staffing models, technological maturity, infrastructure, or organizational readiness. Although the findings may be relevant to similar acute inpatient settings where assistive robots are at an early stage of implementation, they should not be assumed to represent all nursing contexts.

Future research should examine how nurses' perceptions evolve after sustained exposure to assistive robots and should incorporate the perspectives of multiple stakeholders. Given participants' concerns about human touch, counseling, and patient experience, future studies should also explore how patients and family caregivers perceive acceptable uses for assistive robots in inpatient care, particularly for activities involving communication, emotional support, and relational aspects of care. Longitudinal and comparative studies are also needed to evaluate the effects of assistive robots on workload, patient safety, patient experience, staff trust, cost-effectiveness, and long-term sustainability.

Conclusions

This study demonstrates that inpatient nurses form nuanced anticipatory judgments about assistive robots before routine implementation. Participants expressed cautious optimism about the potential for assistive robots to reduce workload and support selected nursing tasks, but their acceptance was conditional on safety, reliability, workflow fit, human oversight, relational care, cost-effectiveness, and organizational readiness.

The findings suggest that assistive robot implementation should not be viewed as a purely technical undertaking. Responsible and successful integration will depend on early nurse engagement, workflow-sensitive design, phased piloting, structured training, clear governance, and safeguards that ensure assistive robots augment rather than undermine nursing practice. Nurses' acceptance depends on whether robotic systems are perceived as compatible with professional judgment, patient-centered care, ethical accountability, and practical realities of inpatient work. By foregrounding the anticipatory stage of acceptance, this study highlights how nurses evaluate assistive robots not merely as technical tools, but as potential change agents that may shape professional work, relational care, safety, accountability, and organizational resource use.

Acknowledgments

The authors acknowledge the participants in this study for sharing their time and insights and the Woodlands Hospital nursing leaders for their guidance and support throughout the study. The authors also thank Yong Keng Kwang for his input on the initial study design and Dong Lijuan, Chia Rui Lin, and Sheena Nishanti D/O Ramasamy for their constructive comments and suggestions, which helped improve the quality and clarity of this manuscript. During manuscript revision, the authors used ChatGPT (OpenAI) to assist with language editing, manuscript organization, reviewer-response drafting, and identification of areas requiring clearer explanation. The authors reviewed, edited, and verified all AI-assisted output, including references and substantive claims, and take full responsibility for the accuracy, integrity, and final content of the manuscript. ChatGPT was not used to generate or analyze study data, conduct coding, develop themes, or make final analytic interpretations.

Funding

This work was supported by the Woodlands Health Small Projects Utilising Teams (SPROUTS) Grant (SPR5-24-CI-02).

Data Availability

Deidentified data excerpts relevant to the findings are included in the article. Full interview transcripts are not publicly available due to participant confidentiality and ethical restrictions.

Authors' Contributions

All authors contributed to study conceptualization, methodology, investigation, data curation, formal analysis, funding acquisition, project administration, and manuscript writing, review, and editing. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Assessing the current landscape of nurses' knowledge and attitudes is a critical first step in facilitating a smooth and effective transition toward artificial intelligence (AI)–enhanced critical care.

Objective: This study aimed to assess the levels of and factors affecting the knowledge of and general attitudes toward AI in critical care among nurses.

Methods: A cross-sectional correlational design was used with 203 critical care nurses in Hail, Saudi Arabia, using the Nurses' AI Knowledge Questionnaire and the 20-item General Attitudes Toward Artificial Intelligence Scale from May 2025 to July 2025. Data were analyzed using 2-tailed *t* tests, ANOVA, Pearson correlation, and multivariable linear regression. Statistical significance was set at $P<.05$.

Results: Critical care nurses demonstrated moderate knowledge of (mean score 4.93, SD 1.78) and positive attitudes toward AI (mean score 64.39, SD 8.26). A moderate positive correlation was found between knowledge of and attitudes toward AI ($r=0.45$; $P<.001$). In multivariable analyses, older age was associated with lower knowledge (≥40 years: β=−1.29, 95% CI −2.12 to −0.45; $P=.003$) and less positive attitudes (β=−8.97, 95% CI −12.49 to −5.44; $P<.001$). Female nurses reported lower knowledge (β=−0.69, 95% CI −1.20 to −0.19; $P=.007$) and less positive attitudes (β=−2.65, 95% CI −4.78 to −0.52; $P=.02$) than male nurses. Greater experience (>5 years) was positively associated with knowledge (β=1.20, 95% CI 0.65 - 1.75; $P<.001$) and attitudes (β=8.08, 95% CI 5.76 - 10.41; $P<.001$).

Conclusions: Critical care nurses in Hail demonstrated moderate knowledge of and positive attitudes toward AI, which varied based on their demographic and professional characteristics. These findings highlight the need to strengthen AI literacy and provide targeted support to groups with lower scores, which may enhance readiness for AI integration in critical care settings.

KEYWORDS

artificial intelligence; AI; knowledge; attitudes; factors; critical care nurses; Saudi Arabia

Introduction

The global health care model is undergoing a great revolution directed by the rapid incorporation of artificial intelligence (AI) [1,2]. AI is defined as a system designed to perceive the environment and take action to achieve specific goals [3]. AI encompasses machine learning, natural language processing, and robotics [2,4]. In medicine, AI has vast and promising potential for enhancing diagnostic precision; personalizing treatment plans; optimizing operational efficiency; and, ultimately, improving patient outcomes [5,6]. This technological shift aligns with global initiatives such as Vision 2030, which actively encourages innovation and digital transformation within its health sector to build a robust, data-driven health care system [7,8].

Critical care units, including intensive care units and emergency departments, represent environments with exceptionally high pressure [9]. Clinicians in these settings are required to process large amounts of complex, real-time patient data to make swift decisions. AI applications can be leveraged for the early detection of patient deterioration, prediction of sepsis, forecasting intensive care unit length of stay, and managing ventilatory support. These capabilities support clinical decision-making and potentially reduce human burden [10]. By

XSL•FO
RenderX

automating routine tasks and administrative burdens, AI can free critical care nurses (CCNs) and physicians to focus on more complex clinical reasoning and direct patient care. This shift enhances both the efficiency and humanistic aspects of treatment [11].

As frontline clinicians, nurses are pivotal to the successful adoption of new technologies in clinical practice [12]. Their role involves continuous patient monitoring, assessment, and execution of complex care plans, making them key end users of AI-driven tools. Therefore, the effective integration of AI into critical care is linked to nurses' acceptance, which is shaped by their knowledge, attitudes, and willingness to incorporate these technologies into their workflow [13,14]. However, the introduction of AI in the nursing domain has sparked debate. While some view AI as a tool to augment nursing practice and mitigate workload, others perceive it as a threat to the essential human-to-human interactions that form the bedrock of compassionate care. This difference in perspective raises concerns about dehumanization and ethical implications [15-17].

A significant barrier to AI's integration is the current underrepresentation of nurses in the development, implementation, and evaluation of AI systems for health care [18,19]. This gap can lead to a misalignment among technological solutions, actual clinical needs, and workflow. Furthermore, studies have indicated that nurses' perceptions of AI are mixed and vary widely based on their understanding of its capabilities, reliability, and potential to replace human judgment [20]. Therefore, assessing the current landscape of nurses' knowledge and attitudes is a critical first step in facilitating a smooth and effective transition toward AI-enhanced critical care.

Previous research has begun to explore health care professionals' perspectives on AI, but studies focused on CCNs within the Middle Eastern context, particularly in Saudi Arabia, remain limited. Understanding the demographic, educational, and experiential factors that influence these perceptions is crucial for developing targeted educational and training programs. As critical care environments become increasingly technologically advanced, ensuring that the nursing workforce is not only proficient but also confident and ethically grounded in using AI is paramount.

This study aimed to bridge this knowledge gap by assessing CCNs' level of knowledge of and general attitudes toward AI in Hail, Saudi Arabia. The findings provide valuable insights for hospital administrators, educators, and policymakers in designing strategies that foster AI literacy and address concerns. The ultimate goal is to harness the full potential of AI to support rather than replace the critical role of nurses in delivering high-acuity patient care.

Methods

Design, Setting, Population, and Sample

A cross-sectional correlational design was used in this study. The target population of this study comprised CCNs employed in public hospitals located in the Hail region. After obtaining institutional review board approval, meetings were conducted with the heads of critical care units across participating hospitals. In addition, formal communication was established with continuing nursing education offices within these institutions. The survey was designed using Google Forms. The link to the questionnaire and informed consent form was disseminated to the CCNs. Participants were first given an electronic information sheet outlining the study's goals, procedures, risks, benefits, confidentiality measures, and voluntary nature of participation. Data collection was conducted over 3 months, from May 2025 to July 2025. Eligibility criteria required participants to have at least 1 year of continuous experience working in critical care departments, ensuring that only nurses with sufficient exposure to clinical practice in critical situations were included. Nurses serving primarily in administrative roles, as well as those with less than 1 year of critical care department experience, were excluded to maintain a focus on direct patient care providers with adequate professional backgrounds. The required sample size was determined using OpenEpi (version 3.01). On the basis of an estimated total population of approximately 420 CCNs in the region, the minimum sample size necessary to achieve adequate statistical power was 201, with a 95% confidence level and 5% margin of error. To enhance representativeness and mitigate the potential impact of nonresponses, 220 self-administered questionnaires were distributed. Of these 220 questionnaires, 203 (92.3%) were returned. The electronic survey required responses to all the items before submission; therefore, there were no missing data.

Instruments

The questionnaire consisted of 3 parts. In the first part, the characteristics of the nurses, including their age, sex, marital status, educational level, years of experience, type of shift work, unit type, and prior experience with AI in health care, were examined. We used a previously validated tool by Swed et al [21] (the Nurses' AI Knowledge Questionnaire) in the second segment of the questionnaire to gauge nurses' awareness of AI. It consists of 7 yes-or-no questions regarding common AI terms used in health care designed to gauge nurses' familiarity with this key vocabulary. The scoring system is as follows: "yes" answers are scored as 1 point, and "no" answers are scored as 0 points. The total score ranges from 0 to 7, with a higher score indicating a higher level of knowledge regarding AI terminology [21]. As Swed et al [21] noted, the Cronbach α value of 0.795 demonstrated the tool's internal consistency among the subscales. In this study, the reliability of this instrument was confirmed with a Cronbach α of 0.765.

The 20-item General Attitudes Toward Artificial Intelligence Scale (GAAIS) created by Schepman and Rodway [22] constituted the third section of the questionnaire. It gauged nurses' opinions on the use of AI in medical environments. The items are divided into positive (12 items) and negative (8 items). Positive items are scored on a 5-point Likert-type scale, with 1 denoting "strongly disagree" and 5 denoting "strongly agree." Negative items are reverse scored, with 1 denoting "strongly agree" and 5 denoting "strongly disagree." Thus, the scores range from 20 to 100, with higher scores on each subscale reflecting more positive attitudes [22]. According to Schepman and Rodway [22], the GAAIS has demonstrated a high degree of internal consistency, with Cronbach α values for the 12

XSL•FO
RenderX

positive items and 8 negative items being 0.88 and 0.82, respectively. In this study, reliability was confirmed with a Cronbach α of 0.969 for positive items and 0.952 for negative items.

Ethical Considerations

Institutional review board approval was obtained from the University of Hail (H-2025-718) on March 10, 2025, and from the Ministry of Health (2025-37) on March 18, 2025. In compliance with institutional review board approval, informed consent was obtained electronically: participants were required to study the information page before completing and submitting the survey, which constituted informed consent. The participants' anonymity and confidentiality were maintained throughout the study. As the survey platform required all items to be completed before submission, there were no partial responses or missing data. No compensation or incentives were provided for participation in the study.

Data Analysis

SPSS Statistics (version 27; IBM Corp) was used to analyze the data. The Shapiro-Wilk test was used to test for normality of the data ($P>.05$). Independent-sample *t* tests and one-way ANOVA were used to investigate the relationship between the dependent and independent variables. Using multivariable linear regression analysis, significant factors affecting CCNs' knowledge and attitudes were identified. Correlations between variables were assessed using the Pearson correlation coefficient. The *P* value was set at less than .05.

Results

Table 1 shows that most participants were aged 20 to 29 years (121/203, 59.6%), male (129/203, 63.5%), and single (140/203, 69%). Most nurses held a bachelor's degree (141/203, 69.5%), worked rotating shifts (131/203, 64.5%), and had 5 years or less of nursing experience (117/203, 57.6%). Younger nurses showed significantly higher knowledge of ($P=.01$) and more positive attitudes toward AI ($P=.002$) than older nurses. Male nurses reported higher knowledge and more positive attitudes than female nurses ($P<.001$ in both cases). Single nurses scored higher on knowledge ($P=.03$) and attitudes ($P=.046$) than married nurses. Nurses with a master's degree had higher knowledge ($P=.02$) and more positive attitudes ($P<.001$) than those with a bachelor's degree. Additionally, nurses with more than 5 years of experience exhibited higher knowledge ($P=.02$) and more positive attitudes ($P<.001$) than less experienced nurses.

≤5	117 (57.6)	4.67 (1.78)			62.30 (6.91)		
>5	86 (42.4)	5.27 (1.73)			67.23 (9.12)		

[a]*F* test.

[b]2-tailed *t* test.

The mean score for CCNs' knowledge of AI was 4.93 (SD 1.78; range 2 - 7), indicating a moderate level of knowledge. The mean score for attitudes was 64.39 (SD 8.26; range 47 - 95), reflecting a generally positive attitude toward AI (Table 2).

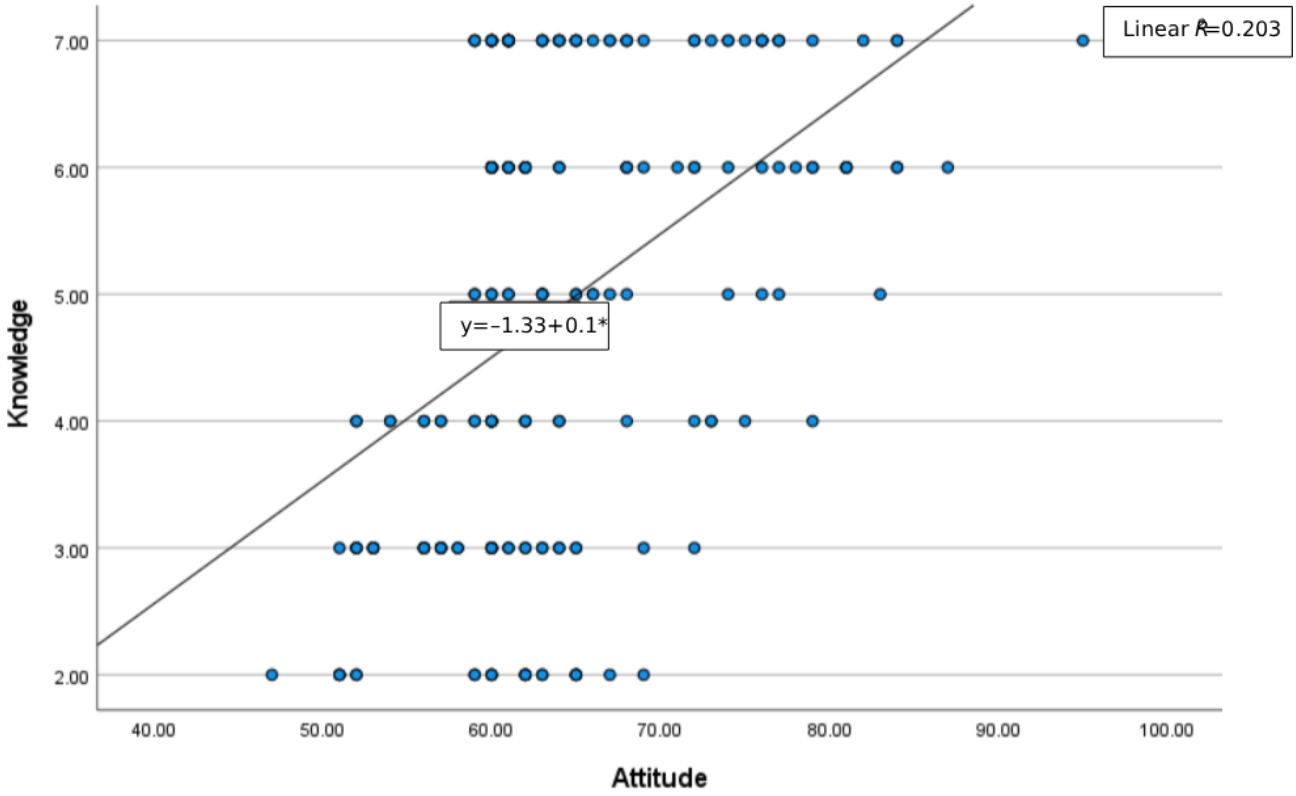
Table 3 shows that there was a moderate positive correlation between CCNs' knowledge of and attitudes toward AI (r=0.45; P<.001). This finding indicates that higher knowledge levels are associated with more positive attitudes.

Table . Means of critical care nurses' knowledge of and attitudes toward artificial intelligence (N=203).

Variable	Score, mean (SD; range)
Knowledge (0-7)	4.93 (1.78; 2-7)
Attitudes (20-100)	64.39 (8.26; 47-95)

Table . Correlation between study variables (N=203).

	Knowledge	Attitudes
Knowledge	1	0.45
Attitudes	0.45[a]	1



[a]Correlation is significant at the .01 level (2 tailed).

Figure 1 illustrates the moderate positive correlation between CCNs' knowledge of and attitudes toward AI. The scatterplot shows that higher attitude scores were associated with higher knowledge levels. The regression line indicates a significant positive linear relationship (R^2=0.20, P<.001), suggesting that

XSL•FO
RenderX

attitudes were associated with approximately 20% of the variance in knowledge.

Figure 1. Scatterplot of the correlation between critical care nurses' knowledge of and attitudes toward artificial intelligence.

The regression models identified several sociodemographic predictors of CCNs' knowledge of and attitudes toward AI. Age and sex were found to be significant predictors of knowledge. Nurses aged 30 to 39 years (β=–0.80; *P*=.02) and those aged ≥40 years (β=–1.29; *P*=.003) had lower knowledge scores than those aged 20 to 29 years. Similarly, female nurses reported significantly lower knowledge scores than their male counterparts (β=−0.69; *P*=.007). In contrast, nurses with more than 5 years of experience had significantly higher knowledge levels (β=1.20; *P*<.001). The model's R^2 was 0.19 (adjusted R^2=0.17; *P*<.001), indicating that the included predictors were associated with approximately 19.4% of the variability in knowledge scores.

Age, sex, educational level, and experience were significant predictors of attitudes. Nurses aged 30 to 39 years (β=–4.81; *P*=.001) and those aged ≥40 years (β=–8.97; *P*<.001) reported less positive attitudes than those aged 20 to 29 years. Female nurses had significantly less positive attitudes than male nurses (β=–2.65; *P*=.02). Conversely, nurses with a master's degree (β=3.38; *P*=.002) and those with more than 5 years of experience (β=8.08; *P*<.001) demonstrated more positive attitudes. The model's R^2 was 0.33 (adjusted R^2=0.31; *P*<.001), indicating that the included predictors were associated with approximately 33.2% of the variability in attitude scores (Table 4).

[b]R^2=0.33; adjusted R^2=0.31; P<.001.

Discussion

CCNs' Knowledge of and Attitudes Toward AI

This study provides a timely investigation of CCNs' knowledge of and attitudes toward AI in the Hail region of Saudi Arabia, a context undergoing rapid digital transformation as part of Vision 2030. The findings revealed a moderate level of AI knowledge (mean score 4.93, SD 1.78) and a generally positive attitude (mean score 64.39, SD 8.26) among CCNs. Crucially, a significant positive correlation was established, indicating that higher levels of AI knowledge were associated with more favorable attitudes. This aligns with the technology acceptance model (TAM), which posits that perceived usefulness and ease of use are key determinants of technology adoption and that these perceptions are inherently linked to an individual's understanding of the technology [23-25]. Our results suggest that educational interventions aimed at improving AI literacy could be a powerful lever for enhancing acceptance among the nursing workforce.

Predictors of CCNs' Knowledge of and Attitudes Toward AI

Sociodemographic analyses yielded insightful results. Younger nurses (aged 20-29 years) exhibited significantly higher knowledge and more positive attitudes than their older counterparts. This generational divide is consistent with the broader literature on technology adoption, where younger individuals, often "digital natives," tend to be more comfortable and familiar with emerging technologies [26,27]. This finding underscores the need for age-tailored training programs that support more experienced nurses in developing comparable levels of perceived ease of use and usefulness, thereby reducing TAM-related barriers among older staff while leveraging their clinical expertise.

Gender emerged as a significant predictor, with male nurses reporting higher knowledge and more positive attitudes than female nurses. This disparity may reflect broader societal and educational trends in the science, technology, engineering, and mathematics fields, where gender gaps in confidence and participation persist [28]. In the nursing context, which is predominantly female in many countries but has a different demographic profile in regions such as Saudi Arabia, this finding underscores the need for equitable access to AI training and leadership opportunities. Ensuring that these opportunities are encouraging and available to all genders is essential to preventing a new form of digital gender divide within the profession. From a TAM perspective, such differences may translate into unequal perceptions of ease of use and self-efficacy with AI systems, highlighting the importance of designing AI training and leadership opportunities that actively foster confidence and perceived control among women to prevent a digital gender divide in nursing.

Educational attainment has a strong positive influence. Nurses with a master's degree had significantly more positive attitudes and higher knowledge scores than those with a bachelor's degree. This finding reinforces the pivotal role of advanced education in fostering a forward-looking, evidence-based, and innovative mindset. This suggests that integrating AI concepts and applications into postgraduate nursing curricula is essential

XSL•FO
RenderX

for preparing future nurse leaders [6,29]. Furthermore, contrary to what might be assumed, nurses with more than 5 years of experience reported higher knowledge and more positive attitudes. This compelling finding challenges the notion that experienced clinicians are resistant to change. Instead, it implies that experienced nurses, with their developed clinical expertise, may better appreciate AI's potential to alleviate cognitive burdens, reduce errors, and enhance patient safety [11].

The regression models indicated that 19.4% of the variance in knowledge and 33.2% of the variance in attitudes were related to demographic factors. However, other variables not measured in this study also played a significant role. These could include organizational culture, quality of previous technology implementation experiences, perceived organizational support for training, and the level of trust in the institution's data governance and ethical frameworks [30,31]. Future research should explore these organizational and psychological determinants to provide a more holistic understanding of the factors that influence AI integration in nursing.

Correlation Between CCNs' Knowledge of and Attitudes Toward AI

The moderate positive correlation between knowledge and attitude (r=0.45; P<.001) strongly implies that resistance or skepticism toward AI is not unchangeable but can be mitigated through education and exposure. Within the TAM framework, this implies that structured education and meaningful hands-on experience can reshape nurses' beliefs about AI's usefulness and ease of use, moving them from passive compliance to active, informed adoption of AI tools in clinical workflows. This finding aligns with the work by Dornan [32], who suggested that a basic understanding of AI is essential for its acceptance and use in clinical practice. When nurses understand how AI works, what it can offer, and what its limits are, the technology becomes less intimidating [32]. This awareness helps them move from being passive recipients of change to being active and informed participants. Such a shift encourages genuine engagement rather than simple compliance [32]. Therefore, the observed link highlights the need for targeted education programs designed to build nurses' confidence and skills in working with AI, ensuring that technology, rather than distance, enhances nursing care. Thus, the primary barrier is not an inherent opposition to technology but a lack of structured and accessible education on what AI truly entails in nursing practice.

Implications for Nursing Education and Practice

The findings underscore the need for specific measures to improve AI preparedness among nurses through education. Older, female, and less experienced nurses had less knowledge of and a negative attitude toward AI, suggesting possible gaps in confidence and exposure that must be addressed through systematic training activities. Incorporating fundamental AI principles and practical applications into undergraduate and postgraduate nursing courses is critical for ensuring that all future nurses are prepared to work with developing technology. In nursing practice, continuing professional development programs that include practical training, simulation-based learning, and case-based scenarios can help improve comprehension and minimize anxiety. Furthermore, nursing professionals with a more optimistic mindset can act as clinical representatives to assist in collaborative learning and ensure the smooth integration of AI in critical care settings. Improving AI literacy across the nursing profession will eventually lead to safer and more efficient clinical practice and successful incorporation of AI-driven strategies in patient care.

These findings are particularly important in the context of Saudi Arabia's ambitious health sector reforms. For AI to be successfully leveraged to build a robust, data-driven health care system as envisioned in Vision 2030, the readiness of the nursing workforce is fundamental. Aligning educational strategies, professional development, and organizational policies with TAM principles by explicitly targeting perceived usefulness, ease of use, and supportive conditions can help translate the current foundational willingness among nurses into sustained, confident use of AI in everyday practice. Our study confirms that foundational willingness is present but must be actively cultivated through targeted, demographically sensitive, and continuous educational strategies.

Strengths and Limitations

This study has several strengths. First, it addresses a significant gap in the literature by focusing specifically on CCNs in the underresearched Middle Eastern context, thus providing valuable insights for regional policymaking and educational planning. The use of validated instruments such as the Nurses' AI Knowledge Questionnaire and the GAAIS enhances the reliability and validity of the findings. Furthermore, the high response rate (203/220, 92.3% returned questionnaires) and rigorous sample size calculation strengthened the statistical power and representativeness of the results for the target population in Hail.

Despite these strengths, this study has several limitations that must be acknowledged. The cross-sectional correlational design captures a snapshot in time and cannot establish causality between the variables. This study was conducted in a single region of Saudi Arabia (Hail), which may limit the generalizability of the findings to other regions or countries with different cultural and health care infrastructures. The reliance on self-reported data for knowledge and attitudes is susceptible to social desirability bias, in which participants may have provided answers that they believed were expected rather than their true beliefs. Finally, the knowledge assessment was based on a 7-item yes-or-no questionnaire, which, while reliable, may not capture the full depth and nuance of a nurse's understanding of AI concepts and applications.

Recommendations

On the basis of this study's findings, the following recommendations are proposed.

Recommendations for Practice

Health care institutions should implement structured, ongoing AI education programs that build basic literacy for all CCNs and provide advanced modules for those in higher-responsibility roles. These programs should use practical, critical care examples to enhance perceived usefulness and ease of use. Targeted support is also needed for older and female nurses

XSL•FO
RenderX

who showed lower knowledge and more negative attitudes through tailored workshops, mentorship, and simulation-based training to ensure equitable AI readiness. Additionally, nurses with master's degrees and more than 5 years of experience should be leveraged as AI champions to mentor colleagues and support effective implementation across critical care teams.

Recommendations for Education

Nursing schools and universities should integrate core AI content—concepts, clinical applications, ethics, and limitations—into undergraduate curricula while expanding advanced, practice-oriented AI training in postgraduate programs, reflecting the strong association between higher education and more positive perceptions. Alignment between academic preparation and workplace training will create a continuous pipeline of nurses who are both knowledgeable about and favorably disposed toward AI in critical care.

Recommendations for Policy

Hospital leadership and AI developers should systematically involve CCNs from diverse age groups, genders, and educational backgrounds in the design, piloting, and evaluation of AI tools because the regression results suggest that attitudes and knowledge are shaped partly by contextual and experiential factors beyond demographics alone. Participatory implementation can improve the perceived relevance and usability of AI systems, thereby reinforcing the positive relationship between knowledge and attitudes and supporting Saudi Arabia's Vision 2030 for a technology-driven, nurse-ready health care system.

Conclusions

This study demonstrated that CCNs in Hail, Saudi Arabia, possess a moderate level of knowledge and a generally positive attitude toward AI, with a clear correlation between the 2. Key sociodemographic factors, including age, sex, educational level, and clinical experience, significantly influenced these perceptions. The findings underscore that the successful integration of AI into critical care is not a technological challenge but a human-centric one. Readiness of the nursing workforce is a critical determinant of success. By investing in comprehensive, inclusive, and continuous education and actively involving nurses in the development process, health care leaders can harness the full potential of AI. This will ensure that these powerful technologies act as supportive tools that augment the clinical judgment and compassionate care provided by nurses, ultimately leading to enhanced patient outcomes and the realization of a technologically advanced, efficient, and resilient health care system as envisioned in the Saudi Vision 2030.

Acknowledgments

The authors express their gratitude to all critical care nurses who participated in their research.

Funding

This research was funded by the Deanship of Scientific Research at the University of Hail, Saudi Arabia, under project RG-23 048.

Abstract

Background: Integrating artificial intelligence (AI) systems into nursing care often encounters obstacles stemming from unmet requirements and insufficient engagement with well-documented sociotechnical pitfalls. Readiness models offer a systematic way to evaluate project preparedness and to build the capabilities needed for successful artificial intelligence in nursing care (AINC) research, development, and implementation. As of yet, an evidence-based AI readiness assessment prioritizing AINC projects and accounting for their diversity in care settings is missing.

Objective: This study aimed to develop a comprehensive artificial intelligence nursing care readiness assessment (AINCRA) to support planning, execution, and evaluation of AINC projects.

Methods: In a sequential exploratory multimethods bottom-up approach to maturity model development, key AI readiness dimensions and attributes were identified to develop a pilot readiness assessment. The pilot version was grounded on insights from an expert workshop (n=21) and expert interviews (n=14), an online survey (n=53), a rapid review (n=292), and a nominal group consensus process. A systematic literature review (n=7) further triangulated AI readiness attributes. Finally, a think-aloud interview study and focus group discussions involving experts (n=18) from nursing practice, nursing science, and AI research and development who had conducted AINC projects prior to data collection validated the attributes.

Results: The resulting AINCRA encompasses 5 core dimensions: regulatory, processual, technical, social, ethical, and community building requirements and aspects. Including 69 attributes and capabilities of AI nursing care readiness, the core dimensions reflect key areas of action where AINC project stakeholders can influence project outcomes. Clinical partners can assess their organization's maturity level in relation to the implementation of AI. An assessment of each dimension and its attributes across 5 maturity levels allows reflecting on and proactively shaping individual project approaches. Overall, experts regarded AINCRA as a useful instrument for the development, management, and evaluation of AINC projects while emphasizing that established principles of good practice in project and data management should not be neglected when using AINCRA as a project management tool.

Conclusions: AINCRA enables practitioners from AI research and development, clinical partners, and nursing and health scientists to plan, evaluate, and enhance AI projects across their lifecycle, thereby supporting effective AI integration in nursing care. While AINCRA was developed within the European and German legal framework for AI in health care settings, respective attributes can be adapted to international requirements.

Introduction

Artificial intelligence (AI) systems promise to contribute to process optimization, workload reduction, patient safety, and quality assurance in nursing care worldwide [1-3]. Following the European Commission's guidelines on AI system definition as entailed in the European Union's Artificial Intelligence (EU AI) Act, AI systems in nursing care refer to machine-based systems developed to function with different degrees of autonomy and potentially adapt over time after being deployed [4]. AI systems process input data to produce outputs such as predictions, content, recommendations, or decisions based on explicit or implicit goals, and these outputs can affect physical or digital environments [4]. Main AI techniques encompass machine learning (ML) approaches including methods such as supervised learning, unsupervised learning, self-supervised learning, and reinforcement learning, or deep learning [4]. Additionally, AI systems include logic- and knowledge-based approaches that infer from encoded human knowledge or symbolic representation of the task to be solved [4]. Logic- and knowledge-based methods encompass areas such as knowledge representation, inductive logic programming, inference engines, expert systems, symbolic reasoning, and search and optimization techniques [4], highlighting diverse methodological possibilities for the development of AI systems in nursing care. Currently, opportunities for AI system development arising from applying generative AI models specifically trained on electronic medical record (or nursing record) data [5] further expand the scope of methods and use cases.

While AI is already supporting clinical decision-making of nurses in wound assessment [6] or diabetes care [7], monitoring and detection of risks and clinical deterioration throughout the care process [8-10], or nursing documentation via hybrid speech assistants [11,12], many unexplored use cases in acute and long-term care persist [13]. Furthermore, studies aiming to assess the effectiveness of AI systems in nursing care under real-world conditions using designs capable of determining cause-and-effect relationships are still scarce [14,15]. The potential benefits and expectations of artificial intelligence in nursing care (AINC) are high and are emphasized by professional associations and the World Health Organization, in light of growing global challenges to ensure high-quality care despite a declining number of health care professionals and increasingly complex disease and care trajectories of patients [16,17]. Funding bodies are investing in AI research and development (R&D), and the number of AINC projects is growing. In Germany, for example, the Federal Ministry of Health and the Federal Ministry of Research, Technology and Space support AINC projects in the areas of new care models, health care research, assistance of nurses and family caregivers, and enhancing autonomy and quality of life of people in need of care.

AINC projects face not only technical and regulatory requirements (eg, aspects of interoperability, compliance with national or international data laws, such as privacy and data protection laws, medical device regulations, or the EU AI Act) but also procedural, ethical, and social challenges of AI development and deployment (eg, the micro-, meso-, and macro-level impact of AI on nursing care, ethical-normative values of nursing and care, and translational factors such as acceptance of AI or added practical value) [14,18,19]. This applies to the planning, implementation, and evaluation phases of AINC projects. Project leaders encounter different care settings with many possible use cases for AI (such as AI systems for care in hospitals, nursing homes, outpatient care, or in initial, further, and continuing education) [2], with each care setting influencing the project process with its own unique organizational logic and culture. AI systems may be more complex to implement and use than many other digital technologies [20]. Organizations that aim to develop, deploy, and use AI systems face technical and human-centered challenges that can be overcome by building AI maturity and ensuring they are well-prepared for AI within their organizational context [20-22]. We propose that the same holds true for AINC projects, for which a systematic, comprehensive reflection of AI readiness attributes across various dimensions can help align, justify, and document actions and strategies across all project stages, and may serve as a motivation to foster communication and collaboration within interprofessional project consortia.

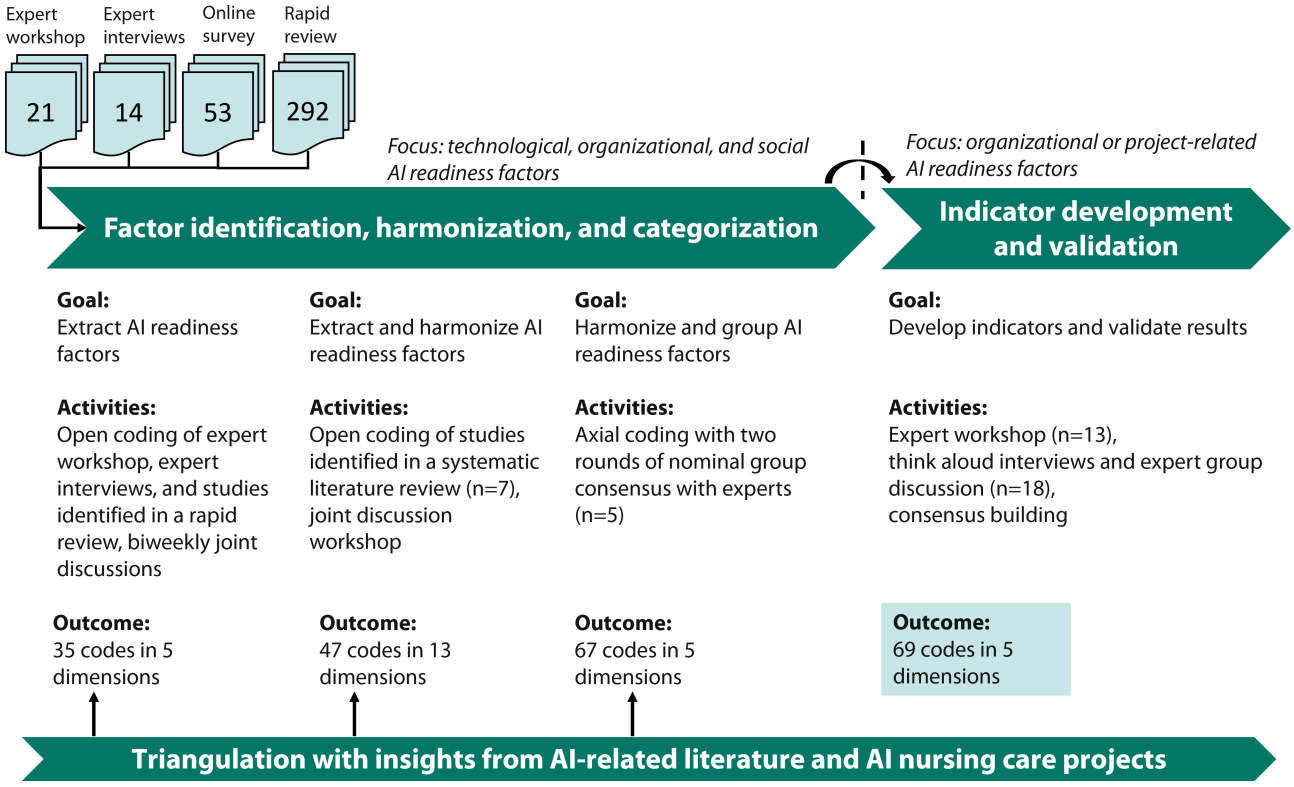
Maturity or, often synonymously used, readiness models provide structured guidance to enhance capabilities for effective (AI) technology integration [20,23,24]. Transferred from insights on organizations, readiness models provide features and guidance that help AINC projects to consider context-specific factors while not overlooking humanistic objectives and aspects of sociotechnical interplay next to focusing on technical and regulatory requirements [20,21]. There is a growing body of both theoretical and empirical research on readiness and maturity models [24]. Among these, stage growth models are particularly prevalent in information systems research [24]. These models typically define a progression of maturity levels, applied to an organization or process, ranging from minimal capability to full maturity, outlining an expected or ideal development path, accompanied by a measurement instrument [23,24]. As an example, in hospitals, the maturity model for ML systems [25] is structured around 3 dimensions: organization, adopter system, and patient data. These are broken down into 12 attributes and assessed across 5 maturity levels [25]. The model addresses aspects such as ML strategy, technical infrastructure, ML expertise, user acceptance, and the quality and standardization of patient data [25]. However, so far, an evidence-based AI readiness assessment prioritizing AINC projects and accounting for their diversity beyond R&D on ML in diverse nursing care settings is missing. Hence, the objective for our research is to develop a comprehensive artificial intelligence nursing care readiness assessment (AINCRA) tool for planning, conducting, and evaluating AINC projects responsibly. Therefore, in a sequential exploratory multimethods study, we ask the following questions:

1. What are dimensions, attributes, and levels of a readiness assessment intended to support those responsible for AINC projects as a reflection tool during the planning, implementation, and evaluation phases of their projects?
2. How do experts with practical experience in planning, implementing, and evaluating AINC projects understand

XSL•FO
RenderX

and use the AINCRA, and how do they assess it with regard to selected evaluation criteria?

We present AINCRA as a tool for decision-makers in R&D and clinical partners in AINC projects to reflect on their handling of prerequisites and aspects of these projects and for designing AINC projects in a promising and successful way. Further, we compare with recommendations for the development of maturity models and common criticisms of maturity models [24] to highlight methodological strengths and weaknesses of AINCRA.



Methods

Overview

We conducted a sequential exploratory multimethods study following established design recommendations and structures of maturity models [20,23,24] to develop AINCRA. Figure 1 presents the research approach, highlighting goals, activities of data collection, analysis, and outcomes for the study period lasting from December 2021 to March 2025. In a stepwise bottom-up approach, we categorized AI readiness factors into capabilities, applying an iterative validation process. Building on preliminary qualitative and quantitative findings from our research group [3,13], we extracted AI readiness factors and conducted a complementary systematic literature review to inform the development of an initial AINCRA version as well as guiding questions for subsequent think-aloud interviews and discussions with experts. Additionally, we triangulated results and findings from the different steps of data collection with insights from AI-related literature and from 8 AINC projects we had been involved in or which we had been accompanying during the last 5 years by repeatedly comparing preliminary drafts of AINCRA with documented project plans to assess completeness.

We follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 statement for reporting systematic reviews (Checklist 1) [26]; furthermore, the COREQ (Consolidated Criteria for Reporting Qualitative Research; Checklist 2) [27] and criteria on mixed methods reporting [28] guide this research where applicable. A short description of the rationale, basic methods of development, and a short generalized overview of the AINCRA dimensions has been published elsewhere [29].

Figure 1. Overview of the research approach. AI: artificial intelligence.

Systematic Literature Review: Information Sources, Eligibility Criteria, and Review Protocol

Leading health and information sciences databases Scopus, PubMed, ACM Digital Library, AIS Electronic Library, and EconLit were searched in February 2023 for English- or German-language articles published from 2012 onward which either refer to a specific AI readiness assessment tool (defined by containing at least one specific question or evaluation criterion of AI readiness or maturity with a qualitative assessment option) or refer to frameworks or single studies that theoretically or empirically define AI readiness. Further, articles had to refer to AI readiness of institutions, organizations, projects, teams, or higher-level units (sectors and disciplines). Health care and nursing settings differ from other business sectors and societal areas, among other things, in that they often process highly sensitive personal data and aim to make it usable for AI systems. In addition, they are based on different sociocultural and organizational logics compared to, for example, the agricultural or logistics sector or the timelines and work culture of data science [30]. Therefore, following the assumption that AI readiness models established for other

XSL•FO
RenderX

sectors cannot be transferred directly to the nursing care context, publications had to refer to nursing or health care settings. Eligibility criteria were established before conducting the initial searches, and a review protocol was developed but not registered.

Search Strategy and Selection Process

The search strategy followed a block building approach [31] applied to title, abstract, and keyword searches using the Boolean operator OR within a single block and the Boolean operator AND across blocks to combine the search terms and synonyms for the blocks encompassing "artificial intelligence," "readiness," and "assessment" are depicted in Multimedia Appendix 1. Two independent reviewers (KS and DW) screened titles, abstracts, and full texts according to predefined inclusion and exclusion criteria using the online resource Rayyan [32]. Conflict between reviewers was resolved by including a third reviewer (DD).

Data Collection Process and Data Items

Data extraction was carried out by one reviewer (KS) in a data extraction form created in Microsoft Excel for this purpose. Data items extracted from each included study entail the following: reference (author, year of publication, and title), country in which the study data were collected, objective of study, study design as stated, setting as stated; population: type and sample size (N); definition of AI: presented (yes or no), definition as stated; AI readiness: addressed (yes or no), definition as stated, explicit readiness assessment presented (yes or no), level of application (organization, project, team, and setting), health or nursing care addressed (yes or no), reporting of attribute origin (yes or no), origin of attributes as stated, number of attributes, description or labels of attributes, and labels of dimensions; readiness framework: presented (yes or no), name as stated, empirically tested (yes or no); success factors and challenges: reported (yes or no), success factors and challenges as stated; limitations as stated; ethics vote obtained: yes or no; funding; conflicts of interest. Missing data were coded as not reported.

Study Risk of Bias Assessment, Effect Measures, and Synthesis Methods

As a conclusion on the effectiveness of interventions was not an intended result of the systematic literature review, we did not conduct a risk of bias assessment and other assessments associated with good practice of methodology for meta-analysis. Results were summarized narratively after inductively developing structuring categories for readiness descriptions and dimensions, as well as for readiness attributes. Key findings are described narratively in the results section and supplemented with tables and figures where appropriate.

Think-Aloud Interviews and Group Discussions

Think-aloud interviews and group discussions were conducted online and digitally recorded with OBS Studio (version 29.1.3; OBS Project) in December 2024 and January 2025. Due to individual availability, 3 experts did not participate in a group discussion but answered group discussion guiding questions (Multimedia Appendix 1) in an interview following the think-aloud task. Details about the involved researcher's background and relationship with participants are provided in Multimedia Appendix 1.

Selection and Recruitment of Expert Participants

We applied a purposive sampling approach [33] by sending personalized, electronic invitations to 42 experts who had either been actively involved in AINC bar camps held by our study team in the past or had conducted and published AINC-related R&D in Germany and were known to the study team. A total of 19 of 42 experts replied (response rate of 45.24%), and 17 experts consented to participation. The reason for nonparticipation was unavailability during the data collection phase. Additionally, all project leads of AINC projects in the German funding program "Making Repositories and AI Systems Usable in Everyday Care" were contacted via email and invited to participate or invite members of their project teams to participate. The possibility for participation was also advertised in the newsletter for said funding program, resulting in recruitment of one participant. We also asked the funding body to propose additional experts but did not receive a response.

Ethical Considerations

The ethics committee of the German Society of Nursing Science granted ethical clearance and approved this study (application 22 - 030). Participation was voluntary, and participants received no monetary or immaterial incentives or compensation. After receiving written information including statements on data protection, privacy, and confidentiality as well as concordance with the European General Data Protection Regulation, all participants provided a written informed consent to participation as well as to the pseudonymized analysis of the data obtained and to the publication of anonymized results. The study was not of an interventional nature. Participants were considered a nonvulnerable population, and participation was not classified as of particular risk.

Data Collection

An interview guideline structured and semistandardized the data collection process, which started with a 5-minute introduction of the interviewers, including their academic degree, field of research, and personal involvement in the research project, followed by an overview of the data collection process, an explanation of data protection, consent, and voluntary participation. After that, participants were asked to introduce themselves (name, work setting, and focus) and provide a short statement on their experiences with AINC projects and implementing AINC settings. A 10-minute introduction to the objectives of the study and AINCRA, during which participants were able to ask questions for clarification, made way for the 30-minute think-aloud interview. Participants were assigned to online breakout rooms with 1 or 2 members of the study team who also took field notes. The AINCRA dimension to be discussed was accessible on a Miro Board on which participants could navigate freely. Using the prompt outlined in the "Results" section, participants reflected on an AINC project they either had conducted, were conducting at the time of data collection, or were planning. They were asked to imagine that they are alone in the room and to talk to themselves. All thoughts were allowed to be expressed. If they

XSL•FO
RenderX

were silent for a longer period, the interviewer asked them to continue to speak. Concurrent verbal probing [34] completed the think-aloud interview strategy. After the think-aloud interview, participants were guided into an online meeting room, where one researcher (KS) moderated the 35-minute group discussion structured by the guiding questions (Multimedia Appendix 1). Other researchers took field notes and asked follow-up questions at the end of the discussion but did not intervene. Guiding questions were based on prior national research on maturity model development [35], and refined in consultation with project members. A 5-minute exit phase concluded data collection, during which participants were informed about the availability of results and invited to the final study event. Afterward, researchers held a 15-minute debriefing to discuss key impressions and themes from their field notes.

Qualitative Content Analysis

Applying a deductive qualitative content analysis approach [36], coding was done by 5 members of the study team (KS, JA, LB, AN, and JP) using a coding form developed in Microsoft Excel for this purpose. Deductive content analysis allows for retesting existing data in a new context, involving testing of models [36]. Units of analysis are the participants' verbal contributions during the think-aloud interviews and focus group discussion. Audio files recorded during the think-aloud interview were randomly assigned to one coder, who listened to the recording, transcribed anchor statements, and paraphrased them. A second coder (KS) reviewed all transcripts and codes to validate the first coder's analysis. The structured categorization matrix [36] consisted of all dimensions and attributes of the AINCRA pilot version. For each interviewed person and AINCRA dimension, attribute, and level description, statements were documented as anchor statements. The same was done for statements on the relevance of attributes and suggestions made for revision or changes to AINCRA. The coding framework for the focus group discussion followed the guiding questions, with the overall coding process being the same as for the think-aloud interviews, using an unconstrained categorization matrix, where various categories were formed within the deductive framework based on the principles of inductive content analysis [36].

Mixing of Results and Consensus-Building on Final AINCRA Version, Translation Strategy

Overall, our integration strategy consisted of the following steps: deriving AI readiness attributes and dimensions from prior work and the results of the systematic review. Building on this, an initial AINCRA version was developed, including the definition of attributes for discussion with experts. The results of these discussions were taken into account in the development of the final AINCRA version: in a half-day consensus-building workshop, results from the think-aloud interviews and focus group discussions were reviewed by 6 members of the study team and discussed one last time against overlapping or contrasting themes derived from the systematic literature search. Further, consensus on which changes suggested by the experts should be incorporated into the final AINCRA version was established by discussion, and the final AINCRA version and a user manual were developed in German and English language. As the qualitative data collection was conducted in the German language, results were first compiled in German and then translated into English for publication. Primary translation was performed by the first author (KS) who was the main researcher involved in data collection and data analysis. All members of the study team had access to the German-language results and validated and revised the translated results, with multiple researchers having extensive experience in English-language knowledge transfer and dissemination of research results (DF, FB, KWO, MS, JP).

Results

Overview

Multimedia Appendix 2 presents the final AINCRA and Multimedia Appendix 3 contains the AINCRA user manual. An open-access online version of AINCRA is available [37]. In the following, we outline the iterative research process to contextualize the results contributing to the final AINCRA, before presenting an overview of AINCRA and its recommended application.

Preliminary Database

First, we built on preliminary work from our working group which has been published elsewhere: data from a rapid review [3] including 292 publications on AI systems in nursing care, an expert workshop with 21 experts (including nurses, nursing directors, health care managers from hospitals, nursing homes, and home care services, digitalization officers and professionals with experience in digital health or routine nursing data analysis, informal caregivers, nursing scientists, and researchers in nursing education, computer science, AI, and ethics) as well as interviews with 14 experts and an online survey (n=53) were used to identify success factors and prerequisites of AINC projects [13]. Five initial key dimensions (namely, regulatory requirements, processual and translational requirements and aspects, technical requirements, social and ethical aspects, and community building) entailing 35 codes emerged as a result of qualitative structuring content analysis involving deductive as well as inductive category and code building.

Systematic Literature Review on AI Readiness Models in Health Care and Nursing

Second, we conducted a systematic literature review to identify existing AI readiness models focusing on nursing or health care settings and harmonize AI readiness capabilities, attributes, and dimensions with results from the first step. Screening of 4748 records identified from 5 leading health and information sciences databases resulted in the inclusion of 7 single publications (Figure 2) which reported either at least one question or evaluation criterion of AI readiness with a qualitative assessment option or a framework for theoretically or empirically defining AI readiness in health care or nursing care.

XSL•FO
RenderX

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of identification of studies via databases. AI: artificial intelligence.

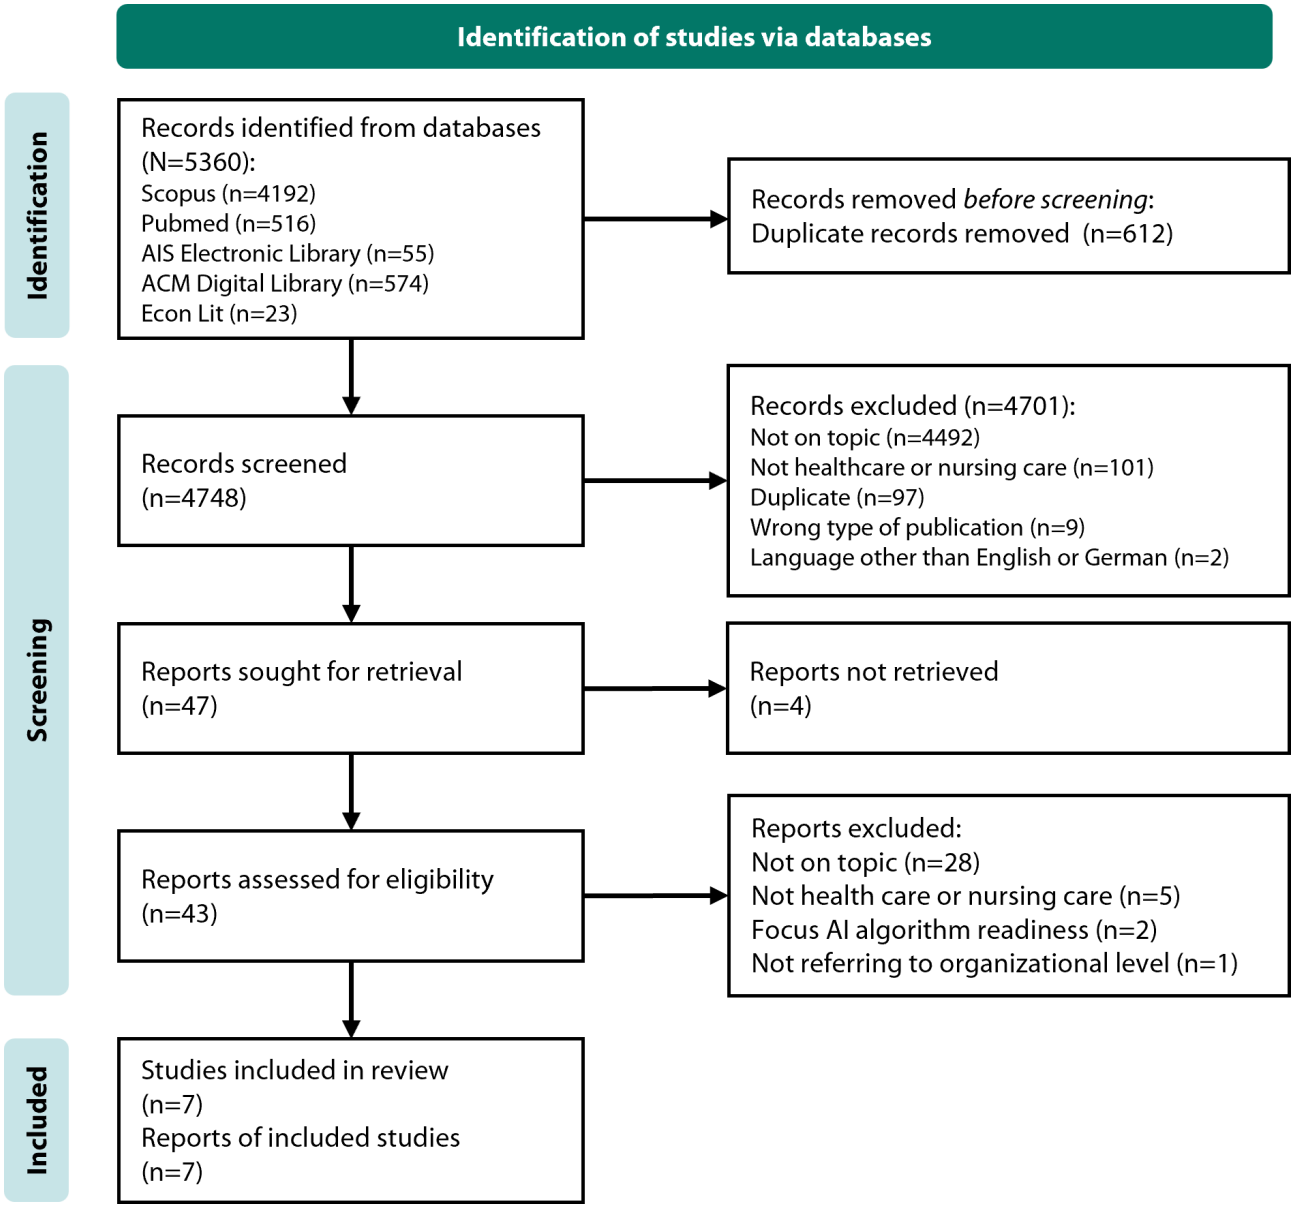


Table 1 provides an overview of the included studies and reports, 3 of which used observational designs with cross-sectional surveys among health care and IT professionals [38-40]. One study applied a qualitative design [25], 1 paper was classified as an expert reflection [41], and 2 papers did not report specific study designs to derive their results from [30,42]. Health care settings focused on either hospitals or selected professional groups or remained unspecified, without referencing specific nursing care settings in acute or long-term care. Overall, we extracted 74 single AI readiness attributes, which we inductively grouped into 47 codes in 13 AI readiness dimensions depicted in Table 2.

[a]AI: artificial intelligence.

Axial coding and contrasting of these 74 readiness attributes with the 35 codes extracted in step 1 provided the database for 2 rounds of nominal group consensus involving 5 experts (2 nursing scientists, 1 ML expert, 1 information systems specialist, and 1 expert representing the German association for digitalization in the social economy with experience in consulting of clinical partners) to harmonize and group AI readiness factors. By merging semantically equivalent attributes and removing those not directly influenced by AINC stakeholders, the AI readiness attributes were reduced to 67 codes in 5 dimensions, serving as the baseline for the development of a pilot AINCRA version.

XSL•FO
RenderX

Indicator Development and Expert Validation

The pilot AINCRA version included feedback from 13 AINC project experts to establish a common AI readiness vocabulary for level distinctions. Building on vocabularies of existing maturity or readiness models [23,44], expert feedback was obtained from researchers and practitioners working in ongoing AINC projects at the time of data collection during a 45-minute bar camp session in September 2024 which was open for participation for all people currently used in 1 of 9 AINC projects in the German Ministry for Research, Technology and Space's funding program "Making Repositories and AI Systems Usable in Everyday Care." Further, level labels, frequencies, and numbering reported in the literature [23,25] were discussed with these experts, resulting in the decision to adopt 5 levels (1: initial, 2: assessing, 3: determined, 4: managed, and 5: optimized) with the possibility to rate an attribute as not applicable depending on the type of AINC project, AI system, or organizational features of clinical partners. The complete AI readiness vocabulary for level distinction is included in Multimedia Appendix 3. The use of the vocabulary and the 67 attributes derived from the third step of the research process as input for GPT-4o (OpenAI)–generated 335 level descriptions, which, after expert review and revision by all members of the study team, were incorporated into the AINCRA pilot version.

Finally, to evaluate the AINCRA pilot version, we applied a think-aloud interview approach [45,46] including a concurrent think-aloud session and reflexive group discussion with 18 experts with a proven track record in carrying out AINC projects to refine AINCRA dimensions, attributes, level distinctions, and descriptions. The think-aloud approach can be useful to "better understand thought processes during assessments as a strategy to describe what [an] assessment is measuring" [46]. Further, the think-aloud approach provided information about the cognitive thought processes of AINC project stakeholders using AINCRA "pertaining to usability problems they would encounter" [47] to reflect on a specific AINC project. Considering possible ways to evaluate maturity models, we followed good-practice recommendations by involving experts "on the type of process that is intended to be improved by the maturity model, but who have not been involved in the actual development of the maturity model" [48].

Characteristics of Think-Aloud Study Participants

At the time of data collection, 10 experts are involved in AINC projects outside of the German funding program "Making Repositories and AI Systems Usable in Everyday Care," while 8 experts are working in ongoing AINC projects in said funding program (characteristics of participants are depicted in Multimedia Appendix 1). Eight experts report less than 5 years of experience with AINC projects, while 5 experts indicate experience of 5 years or longer. These 5, as well as 5 experts who did not report conclusively on the duration of their experience, had also been involved in projects focusing on developing and implementing other digital technologies in nursing care, digitalization, and advancement of IT infrastructures in hospitals and long-term care for several years. Considering the main AINC project stakeholder groups regarding the composition of project consortia, 9 experts represent a nursing or health science perspective, often accompanied by responsibilities and roles connected to project coordination, while in some cases also holding topic-related qualifications or work experience such as nursing informatics expertise. Five experts represent clinical partners in AINC projects, and 5 experts represent AI R&D, 2 of them working for tech companies compared to 3 experts working for institutes affiliated with universities or independent research institutions. In the think-aloud interview, 13 experts reflect on an ongoing AINC project, 4 experts reflect on a completed project, and 1 expert reflects on a project in planning.

Think-Aloud Interview and Expert Group Discussion

Individual 30-minute think-aloud interviews and subsequent 35-minute group discussions were conducted online by 1 to 3 members of the study team in an overall 90-minute session. All participants received an overview of all AINCRA pilot version dimensions and attributes in advance. However, detailed level descriptions were only presented during the interview, along with the verbal prompt to evaluate an ongoing, in planning, or past AINC project they were familiar with. They were asked to do so by using the attributes and level descriptions of one or more selected AINCRA dimensions, referring to a recalled point in time (eg, planning, implementation, or evaluation phase), while verbalizing all their thoughts aloud. Since we anticipated the pilot version to be a complex and time-consuming assessment, participants were only presented with selected dimensions, never all of them. The selection was made with knowledge of the participants' areas of expertise, with a slight emphasis on process-related requirements. This focus was chosen because these dimensions included attributes that are described in the literature as being often neglected in AI maturity models [20], and which, according to our preliminary study, are known to significantly influence project flow and success [13].

We obtained expert statements and comments on 64 of 67 attributes with a total of 70 suggestions for changes to the AINCRA pilot version (Multimedia Appendix 1). Changes suggested included adding definitions, or explanations, or examples for selected terms (eg, "data champion" and "ontological representation"), simplification of terms, reordering and grouping of attributes within 1 dimension or across 2 dimensions, splitting of attributes, and adding of examples in level descriptions (eg, sponsor role as a required responsibility when compliance with the EU Medical Device Regulation is mandatory for the AI system). Some comments highlighted the need for adding information to the AINCRA user manual without resulting in changes to dimensions, attributes, or level descriptions. Overall, 37 of 70 (53%) changes suggested were realized in the final AINCRA version.

In the group discussions, experts rated and discussed the AINCRA dimensions, attributes, and level descriptions they had applied to their own AINC projects in the think-aloud interview. An overview of the discussed evaluation criteria with their respective guiding questions for the discussion can be found in the "Methods" section. In summary, AINCRA was assessed as a valuable tool for AINC project development, management, and evaluation by the experts. However, some

XSL•FO
RenderX

experts pointed out that not all influencing aspects of AINC projects can be foreseen using AINCRA, and that a project process can also be set up without applying AINCRA. Further, general aspects of good practice of project or data management that still need to be considered in each project should not be overlooked when focusing on AINCRA as a project management tool. Multimedia Appendix 1 displays expert ratings and feedback for each evaluation criteria. Results for each evaluation criteria are summarized below and highlighted with selected expert statements.

Benefits and Consequences of Applying AINCRA

Considering benefits and consequences of applying the AINCRA to AINC projects, experts generally see added value. Advantages of applying the complex AINCRA are seen by some as being more suited to larger research projects rather than smaller initiatives or in-house projects, while others also recognize its value for those smaller endeavors. Added value was also noted for project consortia with little prior experience in conducting AINC projects. For clinical partners, AI R&D, and nursing or health science research partners in AINC projects, AINCRA is seen as useful for decision-making, planning, grant applications, coordination among partners, identifying resources and expertise, aligning goals, managing projects, and conducting evaluations. Experts also pointed out AINCRA's usefulness for AINC project funding bodies, as AINCRA may support documentation, monitoring, evaluation, and comparison of AINC projects. Expert participants representing tech companies pointed out that AINCRA may help with their project management activities, client consulting, and long-term support of AI implementations.

> *I think another advantage is that with [AINCRA], you can already identify project risks [...] during project planning, for example the area of social and ethical success factors [...] which is very helpful if such a dimension is already represented here.* [IP2, 00:48:18]

Results of AINCRA may lead to various consequences for AINC projects: positive consequences entail advantages in grant applications for high-scoring applicants, identification of improvement areas and necessary changes, support for go or no-go AINC project decisions, and early reflection on and evaluation of an AI system's practical value. However, an AINCRA result may evoke emotional effects in the individuals conducting the assessment, influencing their motivation to engage with AINC readiness attributes or to push an AINC project forward. Low AINCRA scores may cause frustration or disappointment but can also spark motivation and ambition to improve. However, low-level placement may demotivate clinical partners or discourage participation if initial AINC readiness appears too low and difficult to improve.

> *Especially if the requirements are not met at the beginning, it can quickly give the impression that one doesn't want to do it and doesn't see the benefit for the effort that has to be put in, even though there actually is one.* [IP14, 00:54:16]

Rater Entity

When asked who should carry out the assessment, experts agree that AINCRA is unlikely to be effectively carried out by a single individual. Depending on the dimension and attribute, different individuals should be involved, or AINCRA should be conducted collaboratively, either in a group or in a tandem (eg, between clinical and AI R&D partner) within an interprofessional team. For assessing processual and translational requirements and aspects, suitable raters include experienced personnel from the clinical partner with nursing and digitalization expertise, and IT staff of the clinical partner in collaboration with nursing management with a focus on joint assessments by AI R&D and clinical partners. Conducting AINCRA as a guided, participatory assessment involving frontline nurses was stated as a suitable approach. However, some experts caution against including certain roles (eg, nursing assistants) and emphasize that nurses should be supported during their involvement. Experts also raise the question of who holds responsibility for the AINCRA result, especially if the result impacts, for example, project funding decisions.

> *I think it would be good if the evaluation is done at the start by the project consortium, not by the individual specialists [...] it would be good if everyone in the consortium, with its different disciplines, is clear about [...] all five dimensions [...] so that together they have a clearer idea of what lies ahead.* [IP3, 00:52:05]

Attainability of Levels

Assessing the attainability of AINCRA levels, overall, experts view the levels as realistic and reflective of the diversity among clinical partners and AINC projects. However, not all levels appear to be achievable. They emphasize that this should not necessarily be the expectation for AINC projects, as attainability of levels depends on the dimension assessed and the project context. Level 5 is ambitious and currently hard to reach for most clinical partners. But experts emphasize that level 5 should be a long-term goal and is seen as achievable, especially for clinical partners with extensive AINC project experience, but is considered unrealistic for R&D projects. Level 4 is regarded as the upper realistic limit for R&D projects and a desirable target for clinical partners. Level 3 is also seen as a satisfactory goal for clinical partners. While level 2 was not discussed in detail, for level 1, experts point out that some clinical partners already start AINC projects while scoring above level 1.

> *I would definitely say that we have developed. There were some levels that, from our perspective, were not achievable. But the question is also whether that's the goal. Maybe it's enough to say that you get through with a 3.* [IP11, 00:51:18]

Achievability of Levels

Reflecting on past AINC projects that, from the experts' point of view, were successful, experts discussed the achievement of the AINCRA levels regarding the level at the start of a project and the evolution of levels throughout the project process until completion. Overall, the achievement of AINCRA levels is rated as depending on individual goals and structures of an

XSL•FO
RenderX

AINC project. Progression is inherent to AINC projects, as no project meets all requirements from the start. Participation in an AINC project can lead to the development of new structures and processes at the clinical partner organization that go beyond AINCRA attributes. In contrast, some AINC projects may not show improvement despite great efforts to advance AINC readiness attributes. All types of development trajectories are possible, with advancement, remaining, or regression of levels. Entry levels and basic conditions may help industry (or R&D) partners to more easily identify suitable clinical partners, with level 1 being rated not as a general exclusion criterion, but a knockout criterion for certain attributes (eg, data availability).

> *I do believe that there can be deal-breaker criteria in attributes. Off the top of my head, I thought of data quality and data availability in our project. Especially structural things – if those aren't in place, we don't need to start an AI project. If my data are just scattered on paper.* [IP13, 00:53:24]

Step Size of Levels and Influenceability of Attributes

Step size of AINCRA levels is rated as sufficient, appropriate, and distinct with little in-depth discussion. Influenceability of the AINCRA attributes was discussed in depth: most attributes are considered influenceable within AINC projects. However, some less influenceable attributes are still important, such as regulatory requirements or legal framework changes, which are typically beyond a project's control. Experts highlight influenceability as a reflection criterion, especially when a project receives a low maturity level rating. Attributes considered particularly influenceable are related to attitudes, acceptance, knowledge, and willingness to change of stakeholders at the clinical partners' organization. Limited influenceability is assigned to attributes requiring fundamental corporate decisions (eg, developing and committing to an internal AI strategy) as well as attributes dependent on external conditions of clinical partners (eg, staff shortages, turnover, and financial resources).

> *[AINCRA attributes are] all topics that I can address within the project.* [IP11, 00:55:39]

Availability of Information, Comprehensibility, and Applicability

Discussion of the availability of the information or data needed to carry out the AINCRA revealed that the required information is rated as available or obtainable with reasonable effort for AINC project stakeholders by the experts. Involving additional stakeholders is emphasized, supporting the previous assessment that AINCRA should be conducted as an interprofessional assessment. However, the availability of additional stakeholders may be limited, for example, if IT staff of clinical partners have competing responsibilities and carrying out AINCRA is considered a lower priority compared to other tasks.

> *All [attributes] I have seen so far [.] are definitely such that you can either answer them yourself or at least know who to turn to in order to get the information.* [IP12, 01:14:26]

Regarding the comprehensibility of the AINCRA, some experts consider the instrument to be low-threshold and emphasize its comprehensibility for AINC project leaders. However, some wording is not familiar to all nursing professionals. There is also concern about whether nonnative speakers in nursing leadership or administrative roles will understand the expressions and terminology used in AINCRA. Referring to statements made in the think-aloud interview, experts provide suggestions for logically ordering, rephrasing, or explaining selected attributes, as details of the attributes and level descriptions were rated as not quickly to be grasped.

> *So, I would assess it as very understandable [...] of course, during the [think aloud interview], I naturally picked out the things I understand in order to be able to answer them [...] the comprehensibility depends on who from the consortium is conducting the assessment [...] regarding nursing topics, the IT partners probably would have said, 'I don't understand anything about that at all' [...] it depends on who is sitting in front of it and which professional domain it is.* [IP2, 01:03:33]

For the applicability of AINCRA, experts assess the AINCRA pilot version as a complex, text-heavy instrument that, when applied thoroughly, can take several hours to complete depending on the dimension rated. This long application duration may reduce acceptance of AINCRA. Initial use in particular requires time to understand the instrument and is not necessarily intuitive. However, experts expect that the time required will decrease over time and that the application will become easier with continued use. Conducting AINCRA in an interprofessional team enhances its applicability. Some experts attest to the very good usability of AINCRA, though it should be noted that no expert applied the entire instrument. Application seems challenging for stakeholders in long-term care facilities due to lack of expertise in certain attributes. Experts discussed whether a shortened AINCRA version could be provided.

Comparability and Completeness

Comparability of AINCRA results between AINC projects is assessed heterogeneously between the experts, with some pointing out that comparability is difficult, and others emphasizing that comparability of individual dimensions and attributes is possible. Further, multiple practice partners within one AINC project may be compared with AINCRA, as well as multiple AINC projects within the same funding program, and comparability can be ensured through external evaluation.

> *Of course, it's a self-assessment tool [...] the question is whether it's answered honestly and whether that allows for comparability. If it's evaluated in a review process by external parties, then I do believe that good comparability can be achieved.* [IP8, 00:21:20]

Completeness of AINCRA overall is rated as given, with some experts highlighting suggestions for additions or change. These address the inclusion of staff representatives of clinical partners as important stakeholders, allowing for custom attributes to be added by users, and enabling mapping of multiple clinical partners within a single AINC project.

XSL•FO
RenderX

Overview of AINCRA Dimensions, Attributes, and Levels

AINCRA consists of 69 AINC readiness attributes across five dimensions: (1) regulatory requirements and aspects (9 attributes), (2) processual and translational requirements and aspects (40 attributes), (3) technical requirements and aspects (6 attributes), (4) ethical and social requirements and aspects (11 attributes), and (5) community building requirements and aspects (3 attributes). Table 3 provides an overview of the 5 dimensions. For each attribute, 5 maturity levels are described, a recommendation for stakeholders considered as most suitable as assessors is given, along with a reference to the source from which the attribute or the justification for the relevance of the attribute is derived (Multimedia Appendix 2).

Table . Overview of AINCRA[a] dimensions.

Dimension	Description
Regulatory requirements and aspects (9 attributes)	• This dimension takes into account the necessary legal frameworks and data protection regulations that require an analysis of the data and an examination of data-sharing models to enable the use of AI[b] systems in everyday nursing practice.
Processual and translational requirements and aspects (40 attributes)	• This dimension captures the human, material, temporal, and intangible resources available for AI in nursing care projects in care facilities or hospitals, as well as their general and AI-specific level of digitalization. • It also assesses the maturity of overarching strategies for AI, data governance, and IT governance, as well as plans for long-term external support and evaluation of AI implementation. • Engagement with the implementation of needs-based research and development of AI systems—focused on practical benefits and added value—as well as the existing AI-related knowledge and competencies within care facilities and clinics, is intended to support the seamless integration of AI systems into existing care processes. • This dimension also includes reflection on attitudes toward AI, acceptance of AI technologies, and trust in their use in daily nursing practice, to foster adoption and address concerns of those affected by the deployment of AI.
Technical requirements and aspects (6 attributes)	• This dimension addresses the availability and functionality of the technical infrastructure, including aspects of data protection and data security, which are essential for reliable data use and analysis. • To ensure smooth, secure, and efficient data integration and exchange between different systems and stakeholders in everyday nursing practice, this dimension also considers the integration of AI systems into data infrastructures or data platforms, as well as the use of technical interoperability standards and nomenclatures.
Social and ethical requirements and aspects (11 attributes)	• This dimension encompasses ethical and methodological considerations related to voluntariness, privacy, fairness, and transparency, as well as the ethical and normative value orientations of the field and individual practice partners. • Engaging with the impacts of AI use at the micro, meso, and macro levels, along with a responsible approach to data handling, is intended to support the use of AI systems in everyday nursing practice.
Community building requirements and aspects (3 attributes)	• This dimension aims to promote a network that strengthens knowledge exchange and the collective advancement of AI systems in everyday nursing practice. Researchers, developers, and stakeholders from nursing practice and nursing management are involved in this network.

[a]AINCRA: artificial intelligence nursing care readiness assessment.

[b]AI: artificial intelligence.

AINCRA dimension 1, regulatory requirements and aspects, involves the assessment of how detailed and specific methodological and regulatory decisions, definitions, and limitations are being addressed by an AINC project. This includes, among other things, attributes reported by Pumplun et al [25] for analyzing the dataset, as well as the operationalization of data-sharing models [30,41,49]. In the latter case, for example, the degree of finalization and the progress of the implementation of the model serve as reflection criteria. This dimension also relates to the engagement with requirements arising from the EU AI Act. AINC project stakeholders recommended for assessing dimension 1 are mainly

XSL•FO
RenderX

individuals representing AI R&D, supplemented by a clinical partners' and nursing science perspective for some attributes. An example of the attributes 1.6 Data-sharing Models and 1.9 EU AI Act, corresponding level descriptions, recommended rater entity, and sources of attribute origin is shown in Table 4.

AINCRA dimension 2, processual and translational aspects and requirements, evaluates the resources, general as well as AI-specific digital readiness, and strategic planning in place for implementing AINC. It considers infrastructure, staff skills, governance, and external support, as well as how well AI aligns with care needs and existing workflows. It also examines staff attitudes, acceptance, and trust in AI to support successful integration into everyday practice. Most attributes are targeted at the clinical partner, whose expertise is crucial for assessing this dimension and which needs to be supplemented by nursing science and AI R&D expertise to arrive at a comprehensive assessment. This is reflected, for example, in attributes targeting the degree of digitization, which includes the use of data quality standards [25], the availability of data champions [30] as a personnel resource, or the systematic demonstration of practical benefit and added value of an AI system (Table 4).

AINCRA dimension 3, technical requirements and aspects, focuses on the technical infrastructure needed for reliable and secure data use in AINC projects. It includes data protection, system integration, and the use of interoperability standards to ensure smooth data exchange and effective AI implementation in clinical practice. The main AINC project stakeholder to assess dimension 3 is AI R&D. While the technical infrastructure at clinical partner sites is an essential and priorly described prerequisite for AINC project success [30,41,49], we recommend especially assessing IT infrastructure with a focus on AI compute capabilities and dedicated hardware, for which requirements are often underestimated or not clearly communicated between AI R&D and clinical partners during initial AINC project planning (Table 4).

AINCRA dimension 4, ethical and social requirements and aspects, covers ethical and methodological aspects such as voluntariness, privacy, fairness, and transparency. It also considers the values of the nursing field and its practitioners, as well as the broader impacts of AI use and responsible data handling to support ethical AI integration in daily nursing care. Dimension 4 should be assessed from a multifaceted perspective, including nursing science and clinical partners. In collaboration with clinical partners and AI R&D, nursing scientists should drive the assessment of whether and how structured engagement with ethical-normative values of nursing and care [49] is operationalized in an AINC project. The same holds true for reflecting on the impact of AI on the nursing profession [49], and how this impact informs AI system development, implementation, and evaluation (Table 4).

5.3	Strategic partnerships	• Existing strategic partnerships are unknown or there are no strategic partnerships in the AINC project or among individual project partners.	• Initial strategic partnerships are being explored, but have not yet been fully concluded or formalized.	• Strategic partnerships are partially established, but not all partners in the AINC project have strategic partnerships. • Clinical partners in particular do not have strategic partnerships outside of the project consortium.	• Comprehensive strategic partnerships are established. • Clinical partners also have strategic partnerships outside of the project consortium. • Existing strategic partnerships are regularly reviewed and expanded, especially on a national level.	• Proven and effective strategic partnerships are established for all partners in the AINC project. • Existing strategic partnerships are continuously and internationally expanded.	Not applicable	• AI R&D • Nursing • Science • Clinical partner	[42]

[a]AINCRA: artificial intelligence nursing care readiness assessment.

[b]AINC: artificial intelligence in nursing care.

[c]AI: artificial intelligence.

[d]R&D: research and development.

[e]EU: European Union.

[f]Data Champions understand the types of data generated at the clinical partner, advocate for proper data handling, and mediate between nursing staff and IT. They ensure data are correct, complete, and up to date, identify and resolve data collection issues, enhance staff data literacy through training, and raise awareness about the importance of data in nursing care and research.

AINCRA dimension 5, community building requirements and aspects, promotes a collaborative network to support knowledge exchange and the shared development of AI systems for nursing care, involving researchers, developers, and professionals from nursing practice and management, ideally reaching beyond single-project boundaries and striving for national and international networks and shared knowledge. All AINC project stakeholders can assess dimension 5 with AI R&D and nursing science, especially reflecting on their involvement in technical knowledge transfer [49], while clinical partners should also reflect on existing strategic partnerships and how to foster these [42] (Table 4).

Applying AINCRA

AINCRA is primarily designed as a self-assessment tool for AINC project partners. It addresses topics such as the use and benefit of AINC, data representativeness and sharing, participatory design, and ethical and professional implications of AI implementation. AINCRA can be used at any project stage: a single assessment provides a snapshot of current AI readiness, while repeated assessments enable monitoring progress over time. It may also serve as an external evaluation tool. In all cases, AINCRA should be applied by an interprofessional team, ideally involving representatives from

XSL•FO
RenderX

AI R&D, nursing science, and clinical partner organizations. The tool can be used for an entire AINC project or for selected dimensions or sub-areas.

Interpreting AINCRA

In the absence of an internationally agreed consensus on which factors most strongly determine the success of AINC projects, AINCRA does not produce an overall score. Instead, it prompts users to reflect systematically on all dimensions and attributes, which are consistently considered important for project success. AINCRA results provide a snapshot of an AINC project's current readiness with regard to known prerequisites for successful AI development and implementation in nursing care. The tool can be used in context analysis, project planning, and formative evaluation to identify areas for further development or prioritization, and in summative evaluation to reflect on factors that influenced project outcomes. Across all project phases, AINCRA supports alignment, justification, and documentation of strategies while fostering constructive, content-focused dialogue among project partners.

Discussion

Principal Findings

Despite AI's high potential to support nursing care, many use cases in acute and long-term care are still underexplored [13], and R&D projects face multifaceted challenges when designing, implementing, or evaluating AI systems in everyday nursing care. In this study, we systematically developed dimensions, attributes, and levels of AI readiness based on published empirical evidence as well as insights from experts with practical experience in conducting AINC projects. Integrating findings from prior work, a systematic literature review and expert discussions directly shaped the development of AINCRA. Attributes and dimensions identified in earlier work provided an initial conceptual structure that was operationalized in a first AINCRA version. This version served as the basis for think-aloud interviews and discussions with experts during which the relevance, clarity, and completeness of individual attributes were critically examined. Feedback from these discussions led to the refinement and consolidation of attributes and informed adjustments. As a result, the final AINCRA reflects a synthesis of theoretical grounding, empirical evidence, and practical expert insight. The resulting AINCRA comprises 5 dimensions and 69 AI readiness attributes across 5 readiness levels that can guide AINC project planning, implementation, and evaluation. While experts with practical experience in conducting AINC projects rated the readiness level 5 (optimized) as ambitious and often unrealistic for AINC projects, they recognized AINCRA's value and overall benefit to support AINC projects, especially with respect to early identification and thus avoidance of common pitfalls of these projects.

A major strength of AINCRA is its comprehensive inclusion of evidence-based, previously established AI readiness factors, with a focus on processual and translational aspects. Prior research on a sociotechnical perspective for responsible AI maturity models has shown that organizations often focus on technical and business assessments when developing and deploying AI systems, while overlooking critical ethical, social, and human dimensions [20]. We argue that this holds true for AINC projects as well, so that they will benefit from recognizing and systematically addressing the importance of both technical and social aspects [20]. In addition, AINCRA sets itself apart from other freely available or commercial instruments, such as the analytics maturity assessment model promoted by the Healthcare Information and Management Systems Society through its consistent focus on the specific application context of nursing care. Many of the models existing before the AINCRA development have not been thoroughly reviewed by the scientific community. Therefore, they were not identified during the systematic literature review. AINCRA goes beyond preexisting models, offering a framework that is both more specialized and scientifically validated for use in AINC projects. As most attributes were derived from and may be transferred to a global context, we see overall generalizability of our results, even though AINCRA was developed within the European legal framework for AI in health care settings. While experiences of AINC experts stem from a German health care and research system perspective that may differ from other countries' prerequisites and available resources, for example, for funding AINC project staff, technical infrastructure or knowledge transfer and dissemination activities, as well as structures, processes, and outcomes of nursing care, we believe that European-centric attributes can be easily adapted to other regional or national requirements.

Implications for AI R&D, Nursing Science, and Clinical Partner Organizations

Given the widely reported issue that actors from health care and information science often do not share the same domain language in R&D projects and frequently work past one another [50], creating transparency and a common understanding of project aims and key concepts should be a shared goal among AINC project partners. AINCRA contributes to achieving this goal by raising awareness of relevant aspects. It also provides a foundation for decision-making at the project initiation phase, helping to determine which partners need to be involved, at what stages, and with what level of resource commitment. Additionally, it enables a better estimation of the risks and costs associated with AI development and deployment. By operationalizing and making the AINC project's progress more visible across different domains and project partners, it fosters a shared basis for discussion and terminology, promoting more effective collaboration.

Leveraging the potential of AI in health and nursing care requires robust estimates of a variety of factors relevant for such an investment, including implementation time, associated costs, regulatory risks, and technology acceptance among potential users and patients [21,25,30]. These estimates call for a thorough understanding of the status quo of health care institutions with respect to a variety of dimensions as detailed in AINCRA. The structure provided with AINCRA can support strategic decisions on investments by providing reliable insights on the efforts required to implement AI technology in clinical practice. The attributes developed in this study can also help to identify gaps and future areas of improvement with regard to AI technology in nursing practice. In addition, the insights gained in expert interviews help to manage expectations in translating and

XSL•FO
RenderX

disseminating AI research to nursing practice. It is evident that an assessment of AI readiness will be challenging or even impossible without transdisciplinary teams that combine expertise in technical, regulatory, and ethical questions with expertise in nursing care.

Although AINCRA is extensive and complex, by advocating for an interprofessional approach, it enables a comprehensive evaluation of AINC projects, due to its high level of detail, ensuring that no blind spots are overlooked. Furthermore, AINCRA is applicable to a wide range of projects, as the term AI is defined broadly, making it relevant across various areas within the field.

Comparison With Design Recommendations and Common Criticism of Maturity Models

Eight requirements for designing maturity models [23] were applied throughout the AINCRA development process. Table 5 outlines how these requirements were addressed and implemented in this study. Above all, the comprehensive comparison with existing maturity models, alongside an iterative approach and the sequential expert evaluation of attribute and level descriptions, strengthens the presented research.

Table . Incorporation of design recommendations in the AINCRA[a] development process.

Requirement (R) derived from [23]	Incorporation of requirement through...
R1: Comparison with existing maturity models	• Systematic literature review • Further development of own prior work • Focus on AI[b] readiness or maturity models in health or nursing care
R2: Iterative procedure	• Research process with 3 iterations
R3: Evaluation	• Application and rating of AINCRA pilot version through experts
R4: Multimethodological procedure	• Sequential exploratory multimethods design
R5: Identification of problem relevance	• Rating and confirmation of AINCRA's relevance in expert group discussions
R6: Problem definition	• Results of preliminary work [13]
R7: Targeted presentation of results	• Feedback from the target group of intended users • Use of discipline-specific terminology • Development of a standard vocabulary for level distinctions together with the intended users
R8: Scientific documentation	• Study documents • Ethics application • Mandatory reporting for funding body • Open access publication of AINCRA

[a]AINCRA: artificial intelligence nursing care readiness assessment.

[b]AI: artificial intelligence.

Three main criticisms of maturity models [24] should be reflected on regarding AINCRA's internal and external validity: (1) lack of a solid theoretical foundation without grounding elements such as maturity levels and dimensions in established academic literature [24], (2) lack of sufficient empirical support for the selection of dimensions or variables, and (3) lack of a clear definition of how maturity should be measured [24]. While we rigorously aimed to address the first 2 criticisms during development by review of the academic literature and iterative evaluation and consensus building with domain experts, a degree of ambiguity in the measurement of AINC readiness remains. This arises partly from the nature of AINCRA as a self-assessment instrument. On the other hand, it is worth noting that AINCRA provides qualitative but not quantitative criteria for assigning a maturity level. Hence, an answer to the question, for example, whether simply participating in one regional network is sufficient to meet the requirements for community building attributes, or whether involvement in at least 3 different networks is needed, remains open to interpretation. Users may assess individual attributes with varying degrees of realism and flexibility. Further operationalization is therefore strongly recommended.

Limitations and Future Research

Our results have limitations that call for further research. First, experts commented on 66 of 69 readiness attributes only. Attributes 2.39 strategies for long-term external support: software and hardware: upgrades, 2.40 strategies for long-term external support: software and hardware: maintenance, and 2.29 financial resources and investments: exploring alternative financing models for including clinical partners remained without comments. Why these attributes were not addressed, even though they have been identified as relevant for AI [41], is not obvious. Most likely is the limited time span of the think-aloud task, which may have constrained responses. Toward the end of the task, experts focused particularly on attributes

XSL•FO
RenderX

they found interesting or especially relevant. Besides, not all invited experts participated. The findings are based on the expertise of a subset of participants. Although key stakeholders were represented, it cannot be assumed that data saturation was fully achieved, as not all invited experts took part in the study, and data collection concluded after interviewing all experts who had agreed to participation.

Second, as research on organizational AI readiness has previously highlighted as a relevant limitation [21], while AINCRA was developed to systematize key attributes of AINC readiness, overlaps with readiness or frameworks for adopting and implementing other digital technologies can be recognized, such as stakeholder acceptance as a key attribute for technology adoption [51]. However, the project-specific perspective of AINCRA expands preexisting frameworks, which predominantly adopt an organizational perspective, thus providing AINC projects with a reflective tool and instrument to support project management.

Third, we decided against substantially shortening or prioritizing AINC readiness attributes, despite suggestions from some experts. This makes AINCRA more time-consuming and potentially less practical for everyday project work. However, this decision is informed by our experiences with multiple AINC projects over the past 5 years, which show that many projects underestimate their complexity and are affected by domain-specific blind spots that hinder collaboration. At the same time, our findings do not fully clarify how individual attributes interact or which should be addressed together when strengthening AINC readiness. While we applied an established method for maturity model evaluation that is being used in information science for decades [48], future research may strive for validating our results by applying AINCRA to real process improvement activities [48] in future AINC projects.

Conclusion

In a field where many use cases remain underexplored and R&D projects often face substantial barriers, AINCRA offers structured guidance to enhance AI readiness for research, development, and implementation of AI projects in nursing care. AINCRA provides a balanced integration of technical, organizational, ethical, and social aspects of AI readiness, addressing a common shortcoming of existing maturity models that tend to prioritize technical or business considerations. Its nursing-specific focus further distinguishes it from other generic or commercially available assessment instruments, making it both context-sensitive and scientifically grounded. Overall, AINCRA offers both a practical tool for current projects and a foundation for future research and refinement in the evolving field of AI systems in nursing care.

Acknowledgments

The authors declare the use of generative AI in the research and writing process. According to the GAIDeT taxonomy, the following tasks were delegated to GAI tools under full human supervision: Translation. The GAI tool used was: ChatGPT 5. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes. Declaration submitted by: Kathrin Seibert Additional note: We used ChatGPT-5 to assist with translating the German language full AINCRA version and user manual to English language. We used for GPT-4o to generate initial level descriptions based on the AI readiness vocabulary for level distinction developed by the authors for this study.

Funding

This study was funded by the German Ministry for Research, Technology and Space, Grant ID 16SV8835, the Einstein Center Digital Future, Berlin, and the German Research Foundation (Project number: 528483508 - FIP 12). The funders played no role in study design, data collection, analysis, and interpretation of data, or the writing of this manuscript.

Data Availability

All data generated or analyzed for the systematic literature review are included in this published article and its supplementary information files. The datasets generated and analyzed based on think-aloud interviews and focus group discussions are not publicly available, to ensure participant privacy but are available from the corresponding author upon reasonable request. Data are stored in a controlled access data storage at the University of Bremen.

Abstract

Background: The integration of robotic systems into nursing practice is increasingly discussed as a potential strategy to alleviate workload and support care processes in response to demographic changes and staffing shortages. However, the acceptance of nursing staff as primary end users remains a critical determinant for successful implementation. Despite technological advances, the practical requirements and perspectives of nursing staff have not been adequately considered in research and development efforts to date.

Objective: Building on the user-centered development approach applied, this study aimed to examine nursing staff's evaluation of a service robot designed to assist with routine tasks in inpatient care, as well as their intention to use it, while accounting for technology-specific and psychological determinants of acceptance.

Methods: A total of 30 nurses tested the robot across 3 application scenarios (information service, item delivery, and beverage delivery) in a simulated care setting, alternating between the roles of nurse and care recipient. Acceptance-related constructs, including intention to use, were measured using the Technology Usage Inventory. General attitudes toward robots were assessed via the General Attitudes Towards Robots Scale. Participants' prior experience with robotics was also documented. Spearman rank correlations and Mann-Whitney *U* tests were used for analysis.

Results: The robot was rated positively across all dimensions. Usability was high (median 20, IQR 18-21; scale range 3 - 21), as was perceived usefulness (median 21, IQR 16-24; range 4 - 28). Skepticism was low (median 10.5, IQR 7-12; scale range 4 - 28), and accessibility was moderate (median 10, IQR 8-13; scale range: 3 - 21). Intention to use was strong (median 224.5, IQR 157-248; scale range 0 - 300) and correlated positively with usability (r_s(28)=0.505; *P*=.004), perceived usefulness (r_s(28)=0.74; *P*<.001), and accessibility (r_s(28)=0.628; *P*<.001), and negatively with skepticism (r_s(28)=–0.516; *P*=.004). More positive personal attitudes toward robots were also associated with higher perceived usefulness (r_s(28)=0.549; *P*=.002) and greater intention to use (r_s(28)=0.483; *P*=.007). No significant differences in intention to use were found between participants with and without prior robotics experience (*U*=83.5; *P*=.62).

Conclusions: The findings indicate a high level of acceptance among the participating nursing staff for the developed service robot within the tested scenarios. Considering the chosen user-centered development approach, they further underscore the need for strategies that combine participatory design, transparent communication of system capabilities and limitations, and structured opportunities for hands-on experience. Such measures, together with proactive knowledge transfer and skills development, are essential to sustainably leverage the practical potential of service robotics in nursing practice.

Introduction

Background

Against the backdrop of an aging population and a shortage of nursing staff [1,2], robotic assistance is being discussed as a promising form of support in inpatient and hospital care [3,4]. A recent scoping review by Ohneberg et al [5] identified assistive robotic systems in nursing and categorized applications into domains, including information and data-related support, monitoring and safety functions, communication and telepresence, and task-oriented assistance in everyday care processes, alongside socially assistive functions targeting emotional care and cognitive support. Against this broader landscape, this paper focuses on service robotics as one class of assistive robotic systems in inpatient care.

Service Robotics in Nursing: Scope and Status Quo

Service robotics denotes technical systems that support people in the partially or fully automated execution of services and tasks. In addition to information-processing and sensory functions, service robots can move autonomously or carry out complex tasks comprising several work steps and materials [5]. Current developments in the nursing context aim at deploying service robots to support administrative tasks such as digital patient data collection and assistance during medical rounds [6,7]; logistical functions, including the transport of medication, supplies, and laundry [8-10]; as well as physically demanding care activities like patient lifting, transferring, and hygiene-related procedures involving both personal care and environmental cleaning tasks [11-14]. At present, the use of assistive robotic systems in nursing remains heterogeneous and occurs primarily during development phases and pilot implementations, although wider practical implementation is anticipated in the coming years [5,15,16].

Early evidence suggests that diverse stakeholder groups, such as nursing staff, are generally open to the integration of robotic assistance, provided that the technology complements rather than replaces human care [4,17]. The expectation is for robots to act as collaborative assistants, reducing the high workload without fully substituting nurses' tasks [18,19]. Their introduction, however, entails a fundamental transformation of nursing work processes [3,5,20]. Consequently, in light of these systemic changes, end user acceptance emerges as a critical factor in the development and deployment of assistive robotic systems in nursing, as it has been consistently identified as a key enabler for successful implementation, as well as for their effective and efficient long-term use [21,22].

Conceptual Background: Technology Acceptance and Intention to Use

In technology research, acceptance is commonly defined as users' willingness to use a technology for the tasks it is intended to support [23]. This broad definition is typically operationalized in technology-acceptance frameworks through users' perceptions of a technology's characteristics and its suitability for intended tasks and conditions of use. In turn, these perceptions shape intention to use, with intention to use serving as the most proximal predictor of actual system use [24,25].

A prominent intention-based framework is the technology acceptance model (TAM) by Davis [26]. The TAM explains intention to use primarily through perceived usefulness and perceived ease of use, linking these perceptions to attitudes toward using the technology and, ultimately, to behavioral intention. While the TAM has been widely applied in health care contexts, its comparatively narrow focus has been criticized for failing to capture the full complexity of technology acceptance in such settings [27]. This critique aligns with a growing body of research highlighting limitations of established acceptance models and calling for broader conceptual frameworks that account for both technical attributes and individual-level factors, a perspective supported by recent reviews [28,29] and empirical studies [30-32].

In contrast to TAM's parsimonious focus, broader implementation-oriented models such as the unified theory of acceptance and use of technology extend the explanatory scope by incorporating social and organizational determinants relevant to real-world implementation [25]. Diffusion-of-innovation perspectives, in turn, address adoption dynamics over time at the system level [33]. These approaches, as well as more general behavioral and health-behavior frameworks such as the theory of reasoned action, the theory of planned behavior, or the health belief model, were not adopted because this study targets technology-specific acceptance perceptions in a workplace context rather than implementation processes or health behavior change [34-36].

Nursing Staff Perspectives on Robotic Assistance

From this perspective, nursing staff perceptions and acceptance criteria are particularly relevant given their role as the primary end users of assistive robotic systems. Although nursing staff play a central role in implementation and everyday use of such systems, their perspectives have long been underrepresented in technology acceptance research [3,37]. Recent studies have begun to address this gap, offering initial insights into nurses' acceptance criteria. However, findings to date point to a complex and multifactorial picture.

Consistent with prior technology acceptance research, the robot's perceived usefulness remains pivotal. Nurses are more likely to adopt a system that demonstrably reduces workload by assisting with physically demanding tasks such as lifting, transferring, or routine deliveries [3,38,39]. Ease of use is equally critical, as increased operational complexity or system failure can offset intended benefits [40]. Acceptance is further shaped by perceptions of reliability and safety. Only a system that performs dependably and poses no risk to care recipients is likely to be entrusted with responsibilities in patient care [41].

Beyond these technology-related considerations, individual-level factors such as attitudes, perceptions, and prior experiences play a critical role. A key factor is nurses' general attitude toward technology and robots in particular. Nurses who are technologically inclined or have had positive experiences with new technologies tend to be more receptive to robotic assistance [21,32,42,43]. Multiple studies, including a large-scale survey of nursing staff, have repeatedly found that prior experience and knowledge specifically related to robotics positively influence acceptance. Nurses with first-hand experience and

XSL•FO
RenderX

greater confidence in operating such systems consistently evaluate their usefulness and applicability more positively [31,38,44].

Taken together, this evidence suggests that acceptance is not a static reaction to technological features, but a dynamic process shaped by individual attitudes, prior experiences, and progressive familiarization. Moreover, empirical findings highlight the importance of early end user involvement in fostering acceptance. When nurses are engaged in planning, adaptation, and decision-making processes, they are more likely to perceive the robot as useful and aligned with their workflow, which in turn strengthens their intention to use the system in everyday nursing practice [45].

Rationale and Objectives

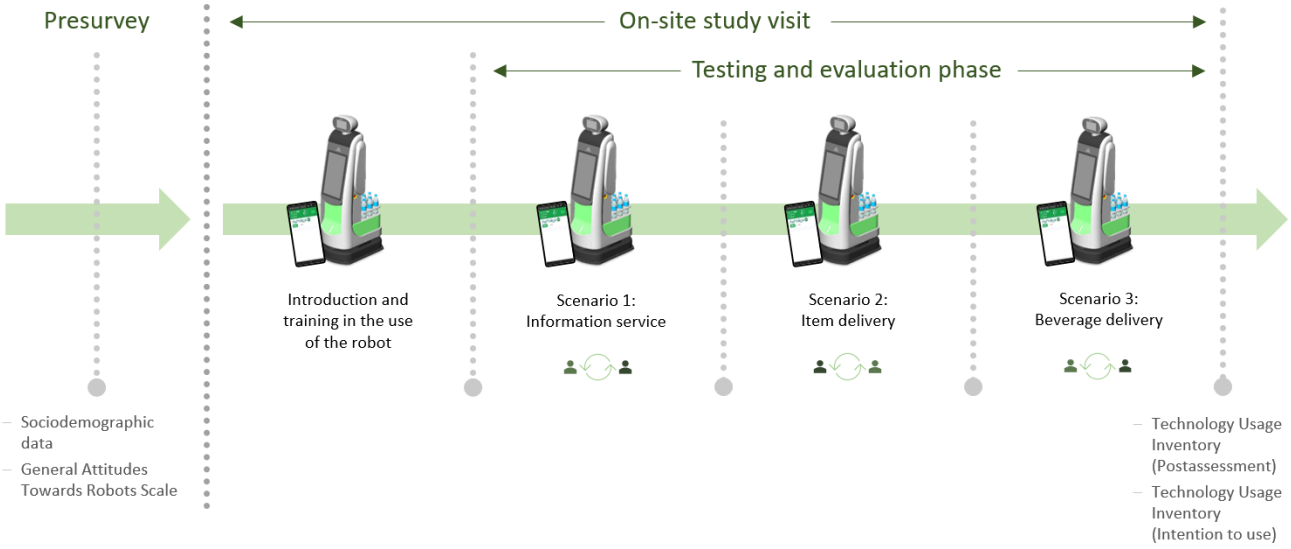
Building on the limited routine deployment of assistive robotic systems in nursing and the multifactorial acceptance determinants outlined above, further evidence is needed from hands-on evaluations of concrete prototypes that are aligned with nursing workflows and professional requirements. Involving nursing staff in participatory development and providing opportunities for direct interaction are widely considered crucial to avoid technology-driven implementation and to ensure that robotic systems fit the practical realities, values, and needs of nursing practice [5,19,20,41].

The research and development project RoMi (Roboterunterstützung bei Routineaufgaben zur Stärkung des Miteinanders in Pflegeeinrichtungen), funded by the German Federal Ministry of Education and Research, aimed to develop a mobile service robot to support routine nonclinical tasks in inpatient care, such as information provision and logistical activities. Nursing staff were actively involved in key phases of the project, including the examination of contextual and ethical prerequisites for robot use [46], investigations of preferences regarding robot design and interaction characteristics [47-49], and the codevelopment of application scenarios, capability requirements, and evaluation criteria for context-sensitive human-robot collaboration [19].

Following this user-centered development approach, the resulting functional prototype was evaluated in an end user study with nursing staff. The study examined participants' general attitudes toward robots, their evaluation of the developed service robot, and their intention to use it. Accordingly, we conceptualized acceptance in terms of intention to use and its multifactorial determinants, integrating both technology-related appraisals and individual-level factors. This paper aimed to advance a differentiated understanding of the usage potential of service robots in nursing, as well as the factors influencing their acceptance and prospective integration within inpatient care settings.

Methods

Procedure



The study consisted of an online presurvey and a subsequent testing and evaluation phase of the developed service robot. To recruit participants, various inpatient care facilities were informed about the study, enabling interested individuals to contact the study team directly. Once interest was expressed, potential participants received the study information and consent form, followed by the scheduling of a telephone consultation. During this call, the study's objectives, design, and procedures were reiterated, and the inclusion criteria were assessed. These included (1) minimum age of 18 years; (2) current or past occupation as a nurse, nursing assistant, geriatric nurse, geriatric nursing assistant, pediatric nurse, occupational therapist, remedial therapist, or physical therapist in inpatient care or daycare; and (3) sufficient proficiency in the German language.

After providing informed consent, participants received a link to the online presurvey, which gathered sociodemographic data and included the General Attitudes Towards Robots Scale (GAToRS). Appointments were then arranged for the testing and evaluation phase, which took place at the research laboratory of the Geriatrics Research Group at Charité—Universitätsmedizin Berlin. Each session involved 2 participants who alternated between the roles of nurse and care recipient. Participants first received structured instruction and hands-on training covering safety procedures as well as the use of the robotic system and its smartphone app for task management and status monitoring.

The service robot was then tested and evaluated across three predefined application scenarios: information service, item delivery, and beverage delivery. These scenarios had been developed and refined in earlier empirical studies conducted within the RoMi project [19,46]. Each scenario was completed twice by every participant, once in each role. To ensure consistency, all received standardized written instructions outlining the required interaction procedures. After performing both roles within a scenario, the session proceeded to the next. Following the test phase, participants completed the posttest section of the Technology Usage Inventory (TUI), including the intention to use (ITU) scale, for the evaluation of the service robot. Each session lasted approximately 90 minutes. Figure 1 illustrates the overall study procedure.

XSL•FO
RenderX

Figure 1. Study procedure.

Robot

The service robot evaluated in this study was developed within the RoMi research project and represents an iteratively adapted prototype. A semihumanoid mobile service robot was selected to match the RoMi focus on routine, nonclinical support tasks, including information provision and logistics. Other systems such as patient-handling, telepresence, or socially assistive robots were not considered within RoMi because they address different task classes.

The developed service robot is based on the workerbot6 platform by pi4_robotics. Throughout the project, the platform was iteratively refined for the care setting, with technical implementation led by pi4_robotics. Iterative refinements were informed by empirical studies on robot design and interaction preferences led by Humboldt-Universität zu Berlin and by industrial design concepts contributed by Hochschule für Technik und Wirtschaft Berlin [47-49]. The authors affiliated with Charité—Universitätsmedizin Berlin contributed the user-centered workstream by conducting studies with nursing staff on practical and ethical considerations of robot use and translating the findings into the development and refinement of application scenarios, interaction sequences, and the associated capability requirements and evaluation criteria for the service robot [19,46].

The research prototype ultimately resulting from the RoMi project and evaluated in this study is shown in Figure 2. The service robot has a height of 175 cm and a weight of 133 kg.

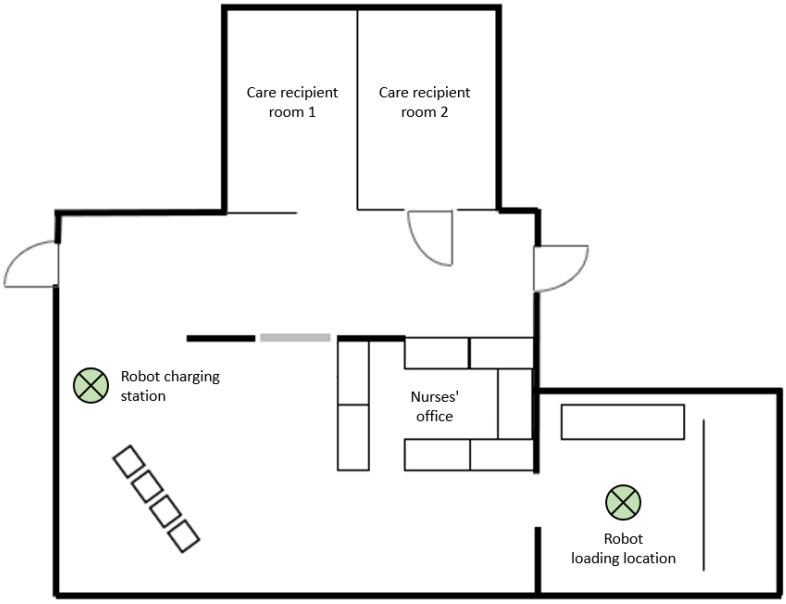
XSL•FO
RenderX

Figure 2. Developed service robot (image used with permission from pi4_robotics).

Based on initial design investigations showing that a human-like appearance can contribute to the acceptance and perceived competence of robots, an anthropomorphic embodiment was chosen [46,47]. The robot's head unit features a screen displaying animated eyes and a mouth, as well as an integrated camera that detects human presence and enables context-sensitive autonomous interaction (eg, in patient rooms or at loading stations). A microphone for speech recognition is also embedded in the head section to enable low-effort voice input, which aligns with caregiver preferences for speech-based interaction [46-48].

The torso is equipped with a front-mounted 21.5-inch touchscreen display that provides graphical feedback on the robot's status and serves as an additional interface for human-robot interaction. This visual channel was intended to enhance interaction transparency and comprehensibility while accommodating potential age- or disease-related changes in the communicative abilities of care recipients [46]. Loudspeakers and an emergency stop button are positioned on both sides of the robot to support clear feedback and immediate shutdown in case of safety concerns. Lateral, arm-like structures function as rails that support a fold-out tray mounted at the rear, enabling the transport and handover of small items without requiring complex manipulation. The back of the robot also houses a beverage dispenser, which is capable of holding twelve 0.5 liter bottles and is equipped with integrated sensors and compartment lighting to support structured loading and ensure correct retrieval during beverage delivery.

The robot is mounted on a mobile platform that enables autonomous navigation based on a map configurable for the ward environment. The robot's navigation was configured with a safety-oriented low-speed profile (maximum 1.4 km/h) appropriate for shared indoor environments, consistent with RoMi project findings that caregivers perceive slower approach speeds as more comfortable and safer [49]. Moreover, the system incorporates a range of obstacle detection sensors. Upon encountering an obstacle, the robot first reduces speed and attempts to navigate around it. If avoidance is not possible, it stops and waits until the path is clear, thereby prioritizing safe behavior in the presence of uncertainty.



Throughout the study, participants used a smartphone app as the primary tool for giving instructions to the robot. The app also provided posttask status information.

Setting

To align the interaction with the robot more closely with the professional care context, a simulated nursing ward environment was set up in the research laboratory (Figure 3). The setup included a nurses' office, 2 patient rooms, and a storeroom serving as the loading station. To minimize mutual influence, partition elements were installed to ensure that participants could not observe each other's interactions while alternating roles.

XSL•FO
RenderX

Figure 3. Setup within the laboratory setting.

Application Scenarios

To standardize exposure to the robot, participants completed 3 scripted application scenarios that operationalized typical nonclinical support tasks and specified role-dependent interactions between the participant in the nurse role, the participant in the care recipient role, and the robot. Tasks were assigned via the robot's instruction and status-monitoring app.

Information Service

The participant in the nurse role created a notification task in the app by selecting the room and entering a free-text message. The robot navigated to the room, signaled arrival with a bell sound, and waited until a person entered its detection area. After person detection, the participant in the care recipient role confirmed readiness to receive the notification via voice or touchscreen. The robot then delivered the message via audio and on-screen output and offered an option to repeat it. If no repetition was requested, the robot returned to the charging station.

Item Delivery

The participant in the nurse role initiated a delivery task in the app by selecting the room and entering a free-text item list. The robot navigated to a predefined loading area and, after person detection, provided voice and on-screen loading instructions. The participant in the nurse role placed the items on the rear tray and started execution on the touchscreen. The robot delivered to the room, signaled arrival, and prompted a confirmation-based handover. The participant in the care recipient role confirmed via voice or touchscreen and retrieved the items, after which the robot returned to the charging station.

Beverage Delivery

This scenario comprised a standard and an extended sequence (phases 1 and 2). In phase 1, the participant in the nurse role configured deliveries for 2 rooms in the app using drop-down selection, loaded beverages into illuminated bottle holders at the loading area following robot guidance, and started execution on the touchscreen. The robot delivered to the room of the participant in the care recipient role using the standard arrival, person detection, confirmation, and pickup sequence. The second room delivery was conducted by study staff to complete a second standardized delivery sequence while keeping participant roles constant. In phase 2, 8 additional deliveries alternated between the 2 rooms. The participant in the care recipient role remained in one room and performed predefined interaction variations for deliveries to their room. These included a misunderstanding prompting repetition followed by rejection, as well as acceptance while using a walker and a wheelchair. In phase 2, the remaining deliveries were again handled by study staff. Rejected deliveries were documented in the app as not completed.

Across all scenarios, the participant in the nurse role performed typical documentation tasks in parallel to autonomous robot operation to reflect realistic time management practices. They also verified task completion in the app and documented the outcomes in accordance with the study protocol. Full scripts and step tables are provided in the supplementary material (Multimedia Appendix 1).

Measures

With regard to sociodemographic variables, the following data were collected: age, gender, highest educational qualification, current occupation, and previous experience with robots.

In addition, the GAToRS was applied. The GAToRS is a validated multidimensional instrument that accounts for both positive and negative attitudes toward robots. It comprises four subscales: (1) personal level positive attitude (P+), (2) personal level negative attitude (P–), (3) societal level positive attitude (S+), and (4) societal level negative attitude (S–). Thus, the scale captures (1) perceived comfort and pleasure and (2) discomfort and fears toward robots on a personal level, along with (3) rational hopes and (4) rational fears on a societal level. The questionnaire shows Cronbach α coefficients ranging from 0.74 to 0.84 across the 4 scales [50].

XSL•FO
RenderX

Furthermore, the TUI was used. The TUI is a validated questionnaire used in technology acceptance research to capture evaluations and selected determinants of intention to use for emerging technologies, encompassing technology-related perceptions and user-related factors. Subscales were selected a priori in line with the study focus on the immediate postinteraction evaluation of the service robot. Accordingly, we administered the postuse subscales usability, usefulness, skepticism, and accessibility together with the separate ITU scale. Reported internal consistencies (Cronbach α) for these subscales range from 0.70 to 0.81 [51].

Participants

A total of 30 participants took part in the study. The mean age was 43.2 (SD 11.2; range 22 - 67) years. The sample consisted of 20 women and 10 men.

At the time of participation, 11 individuals were employed as geriatric nurses and 2 as geriatric nursing assistants. Additionally, 3 participants worked as nurses and another 3 as pediatric nurses. Six were employed as nursing assistants. Five participants had previously worked in nursing and were currently employed in health care delivery-related fields, including nursing education (n=1), case management (n=1), health care controlling (n=1), and research (n=2).

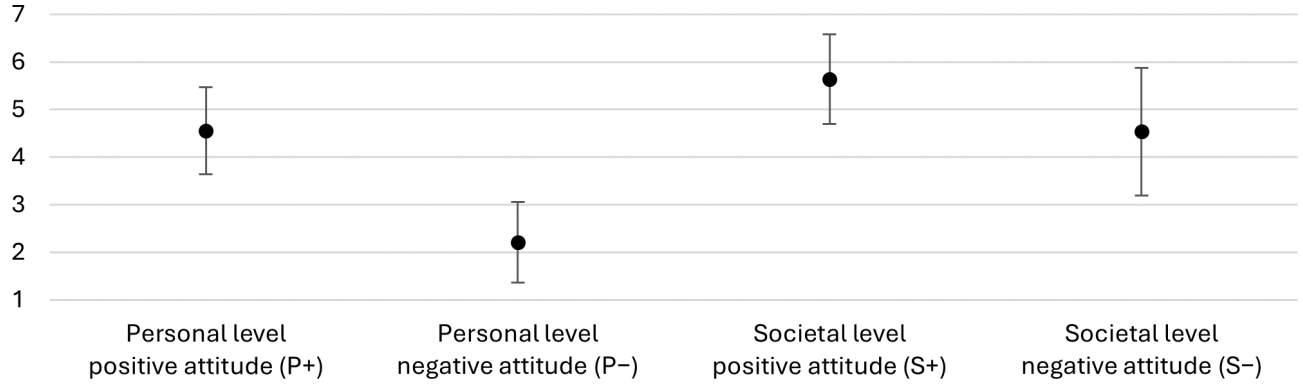
Almost one-third of participants (n=9) reported prior experience with robotics, either in private (n=7), professional (n=1), or other contexts (n=1).

Data Analysis

Data were analyzed using IBM SPSS Statistics (version 29), applying both descriptive and inferential statistical methods. Within the GAToRS dataset, 10 missing items were identified without any discernible pattern. No variable exhibited more than 6.7% missing values. Given that previous studies have shown minimal differences in the performance of various imputation techniques when only 5% - 10% of values are missing [52,53], the use of simple imputation was deemed methodologically appropriate. Accordingly, mean imputation (series mean) was applied in SPSS.

Descriptive statistics are reported as means with SDs or, where appropriate, as medians with IQRs. As normal distribution could either not be assumed or was clearly absent, nonparametric tests were applied. Spearman rank correlation coefficient was used to assess statistical associations, and the Mann-Whitney *U* test was conducted for group comparisons. Statistical significance was set at α=.05, with correlations significant at the 0.01 level additionally highlighted.

Ethical Considerations



The study was conducted in accordance with the Declaration of Helsinki and the International Council for Harmonisation Guideline for Good Clinical Practice [54]. The study protocol was reviewed and approved by the Ethics Committee at the Institute of Psychology, Humboldt-University, Berlin (2023 - 14). All participants provided written informed consent prior to participation. Upon completion of the study, participants received financial compensation of EUR 30 (US $35). Privacy and confidentiality were ensured through data pseudonymization, secure storage of study data, and access restricted to authorized members of the research team.

Results

Participants' General Attitude Toward Robots

To assess participants' baseline attitudes toward robots, the GAToRS was applied (Figure 4). Each subscale yields scores from 1 to 7. Higher scores on P+ and S+ indicate stronger positive attitudes, whereas higher scores on P– and S– indicate stronger negative attitudes.

Figure 4. Results of the General Attitudes Towards Robots Scale subscales. The scale captures attitudes on two levels: personal (positive attitude=P+, negative attitude=P–) and societal (positive attitude=S+, negative attitude=S–). The x-axis displays the 4 subscales, and the y-axis shows the subscale scores. The dots represent the means, and the error bars indicate the SDs. The subscales range from 1 to 7. Higher values on P+ and S+ indicate stronger positive attitudes, whereas higher values on P– and S– indicate stronger negative attitudes.

At the personal level, positive attitudes ranged from 2.6 to 6.6 (mean 4.6, SD 0.9), while negative attitudes ranged from 1 to 4 (mean 2.2, SD 0.8).

At the societal level, positive attitudes showed the highest mean value across all subscales, with scores ranging from 3.2 to 7 (mean 5.6, SD 0.9). In contrast, negative attitudes showed the greatest variability, with scores between 1.8 and 7 (mean 4.5, SD 1.3).

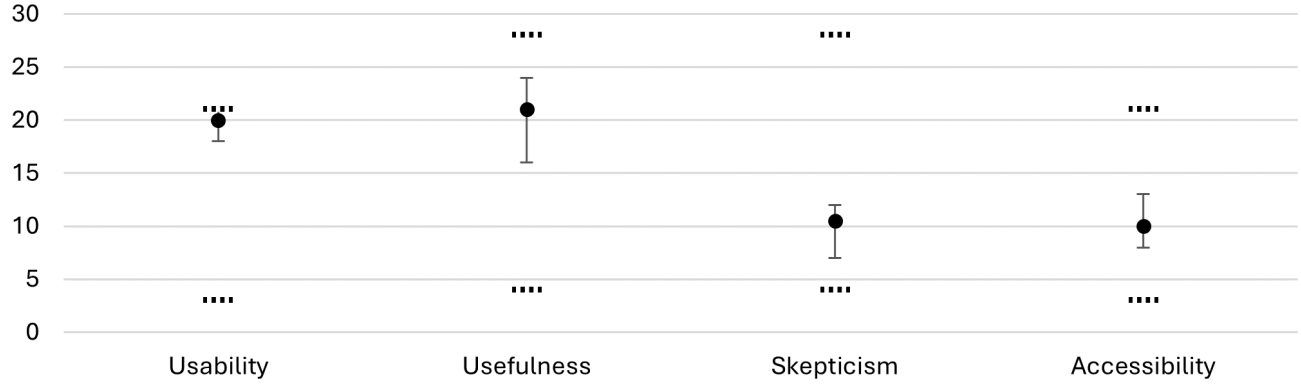
Evaluation of the Developed Service Robot

The general evaluation of the developed service robot was conducted using the TUI, focusing on the immediate postintervention responses. The results included the subscales

XSL•FO
RenderX

usability, usefulness, skepticism, and accessibility (Figure 5), as well as the separate ITU scale (Figure 6). Higher scores indicate greater endorsement of the respective construct.

Figure 5. Results of the Technology Usage Inventory subscales. The x-axis displays the four subscales (usability, usefulness, skepticism, and accessibility), and the y-axis shows the subscale scores. The dots represent the medians, the error bars indicate the IQRs, and horizontal dotted lines mark the scale limits (usability and accessibility: 3 - 21; usefulness and skepticism: 4 - 28). Higher values indicate greater endorsement of the respective construct.



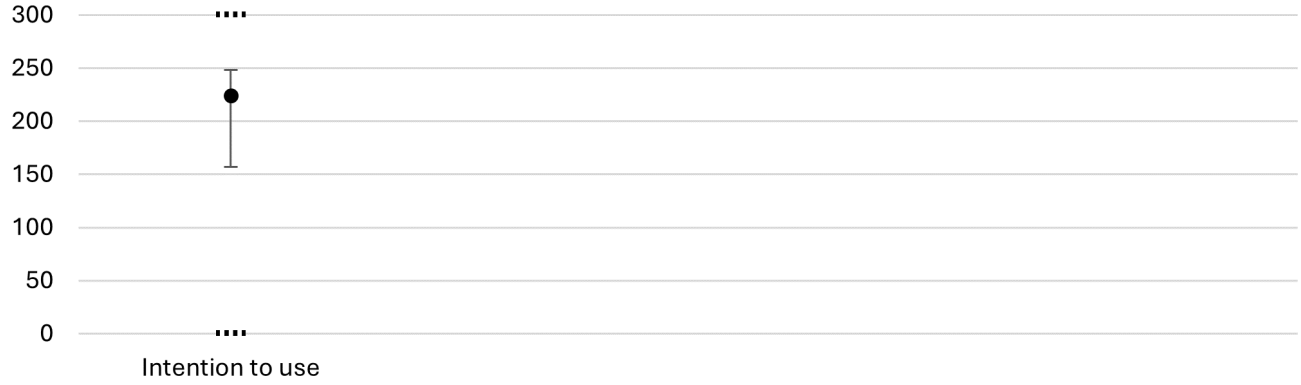


Figure 6. Results of the Technology Usage Inventory intention to use scale. The x-axis displays the scale, and the y-axis shows the score. The dot represents the median, the error bar indicates the IQR, and horizontal dotted lines mark the scale limits (0 - 300). A higher value indicates a stronger intention to use the technology.

Usability scores were between 14 and 21, with a median of 20 (IQR 18-21). Usefulness showed the widest spread among the 4 subscales, with values from 6 to 28, a median of 21 (IQR 16-24). Scores for skepticism varied from 4 to 24, with a median of 10.5 (IQR 7-12). Accessibility was rated between 3 and 21, with a median of 10 (IQR 8-13). For the ITU scale, scores spanned from 0 to 300, with a median of 224.5 (IQR 157-248).

Analysis of Dependencies and Influencing Factors

To measure the strength of the linear relationship between the participants' general attitude toward robots, based on the GAToRS, and the dimensions of the TUI, a Spearman correlation analysis was computed (Table 1).

XSL•FO
RenderX

Table . Results of the Spearman correlation analysis between the General Attitudes Towards Robots Scale and the Technology Usage Inventory.

	Usability	Usefulness	Skepticism	Accessibility	Intention to use
Personal level positive attitude					
r_s	0.057	0.549[a]	–0.317	0.457[b]	0.483[a]

P value	.52	.32	.66	.71	.34
N	30	30	30	30	30
Societal level negative attitude					
r_s	–0.153	–0.387[b]	0.479[a]	–0.576[a]	–0.159
P value	.42	.03	.007	<.001	.40
N	30	30	30	30	30

[a]Correlation is significant at the 0.01 level (2-tailed).

[b]Correlation is significant at the 0.05 level (2-tailed).

P+ showed a significant positive correlation with perceived usefulness ($r_s(28)=0.549$; $P=.002$), indicating a strong effect size [55]. Significant positive correlations were also found with accessibility ($r_s(28)=0.457$; $P=.01$) and intention to use ($r_s(28)=0.483$; $P=.007$), corresponding to medium effect sizes [55]. No significant correlations were observed with usability or skepticism.

P– correlated significantly positively with skepticism ($r_s(28)=0.436$; $P=.02$), suggesting a medium effect size [55]. No significant correlations were found with usability, perceived usefulness, accessibility, or intention to use.

S+ did not exhibit any significant correlations with the dimensions of the TUI.

S– was significantly negatively correlated with perceived usefulness ($r_s(28)=-0.387$; $P=.03$), indicating a medium effect size [55]. Additionally, a significant positive correlation was found with skepticism ($r_s(28)=0.479$; $P=.007$), also reflecting a medium effect size [55]. A significant negative correlation was further observed with accessibility ($r_s(28)=-0.576$; $P<.001$), corresponding to a strong effect size [55]. No significant correlations were found with usability or with intention to use.

To further examine associations between the TUI subscales (usability, usefulness, skepticism, and accessibility) and its ITU scale, an additional Spearman correlation analysis was conducted (Table 2).

XSL•FO
RenderX

Table . Results of the Spearman correlation analysis between the Technology Usage Inventory subscales (usability, usefulness, skepticism, and accessibility) and its intention to use scale.

	Intention to use
Usability	
r_s	0.505[a]
P value	.004
N	30
Usefulness	
r_s	0.740[a]

[a]TUI: Technology Usage Inventory.

XSL•FO
RenderX

Usability was rated slightly higher by participants with prior experience in robotics (median 21, IQR 19-21) compared to those without (median 20, IQR 18-21). Yet, this difference did not reach statistical significance (U=73; P=.31).

Perceived usefulness was also rated comparably across both groups, with slightly higher scores among participants without prior robotics experience (median 22, IQR 16-23) than among those with experience (median 21, IQR 18-26), but this difference also failed to achieve statistical significance (U=82; P=.57).

Regarding skepticism, participants with prior robotics experience reported lower levels (median 8, IQR 7-11) compared to those without (median 11, IQR 7-13). Similarly, this difference was not statistically significant (U=75.5; P=.39).

Accessibility was perceived as slightly higher by participants without prior robotics experience (median 11, IQR 8-13) relative to those with experience (median 9, IQR 8-12). Once again, this difference did not attain statistical significance (U=93.5; P=.96).

Finally, the intention to use was higher among participants with prior robotics experience (median 241, IQR 166-269) than among those without (median 211, IQR 157-247). However, the difference on this scale was not statistically significant either (U=83.5; P=.62).

Discussion

Summary of Key Findings

This study investigated nursing staff's general attitudes toward robotics, as well as their evaluation of and intention to use a newly developed service robot intended to support routine tasks in inpatient care settings. The quantitative analyses revealed a differentiated pattern of findings.

The GAToRS was used to assess participants' perceptions of robots. Ratings on the P+ subscale, which measures trust in robot developers, trust in robots, and comfort in interacting with robots, were moderately high across the sample. Consistent with this, ratings on the P– subscale, assessing discomfort with using robots, apprehension about misunderstandings, and unease in physical proximity to robots, were low and showed little variability. Responses on the S+ subscale, which captures perceived societal benefits of robots such as task delegation, safety, and assistance in meaningful activities, were consistently high. The S– subscale, which includes concerns about job displacement, reduced human interaction, and the necessity for regulatory oversight, yielded moderate ratings with a broader distribution of responses compared to S+.

The evaluation of the developed service robot was carried out using the TUI, focusing specifically on the subscales usability, perceived usefulness, skepticism, accessibility, and the ITU scale. Participants reported high ratings on usability, which measures the extent to which the robot is perceived as user-friendly and easy to operate. Similarly, ratings on the usefulness subscale, reflecting the perceived practical benefit of the robot in supporting everyday activities, were consistently high across the sample. The skepticism subscale, which captures distrust, perceived risks, and critical attitudes toward the technology, received low ratings. In contrast, accessibility, which assesses perceived affordability and the ease with which the robot can be acquired, was rated lower compared to the other dimensions. Participants' ratings on the ITU scale, measuring the reported willingness to acquire and use the robot, were high.

Correlation analyses integrating the GAToRS demonstrated that individually positive attitudes toward robots were associated with higher perceived usefulness and accessibility, as well as a stronger intention to use the system. Individually negative attitudes were primarily linked to elevated skepticism. On the societal level, negative perceptions were associated with increased skepticism and diminished ratings of usefulness and accessibility. Notably, perceived societal optimism toward robots showed no statistically significant associations with any of the TUI dimensions.

Further correlational analyses identified multiple statistically significant linear relationships between dimensions of the TUI and the behavioral intention to use the service robot. Usability, usefulness, and accessibility were positively associated with intention to use, whereas skepticism correlated negatively.

In addition, prior experience with robotics did not exert a significant influence on either the evaluation of the developed system or the intention to use it.

Interpretation of Key Findings

The positive evaluation and high intention to use the developed service robot may be attributable to the user-centered development approach adopted. Within the framework of the RoMi project, the objective of designing the system through the active participation of nursing staff was successfully achieved. The robot was iteratively refined, both technically and with regard to its application scenarios, based on insights from prior empirical studies [19,46-49]. The early and continuous integration of end users facilitated a development trajectory that was aligned with the actual demands of everyday nursing practice, in contrast to predominantly technology-driven design strategies. The favorable assessments of usability and usefulness, as well as the pronounced intention to use the system, thus provide empirically grounded support for the effectiveness of participatory design approaches, consistent with findings from previous research [5,19,41,46].

Analyses of the TUI dimensions further demonstrate that usability, usefulness, accessibility, and skepticism all serve as strong predictors of the intention to use. These findings extend beyond the core constructs of the TAM and underscore the necessity of adapting and expanding the model for health care contexts through the inclusion of additional context-sensitive factors [29].

The strong positive correlation identified between usability and the intention to use the developed robot aligns with established findings in technology acceptance research. Usability has consistently been shown to be a critical determinant of adoption in health care contexts, particularly among nursing staff operating under time constraints [56]. Technologies that are intuitive and easy to integrate into nursing workflows are more likely to be accepted and used consistently [5,57].

XSL•FO
RenderX

Similarly, the strong positive correlation between perceived usefulness and intention to use reflects the importance of demonstrable benefits in practice. In nursing, adoption decisions are often contingent on clear advantages to patient care and workflow efficiency [28]. Robots that reduce workload and improve care outcomes are more likely to gain acceptance [21]. These findings indicate that pilot implementations and use-case demonstrations play a key role in fostering both perceived usefulness and adoption in nursing environments.

The strong positive correlation between perceived accessibility and intention to use further highlights the relevance of economic and logistical considerations in adoption decisions. The data suggest that nursing staff are more likely to engage with robotic systems when these are perceived as affordable and readily available. This finding is consistent with previous research identifying cost-related factors, such as initial investment and maintenance expenses, as potential barriers to implementation [21,58]. Strategies that improve economic accessibility, including subsidies, leasing models, or evidence of long-term cost-effectiveness, may therefore be critical to facilitate broader integration into nursing practice.

The strong negative correlation identified between skepticism and the intention to use the developed service robot underscores the importance of psychological and attitudinal barriers in shaping acceptance. In this study, skepticism was operationalized through items addressing perceived risks, potential disruption to daily routines, and a negative balance of expected benefits and drawbacks. These findings are consistent with previous research showing that concerns related to safety, reliability, and professional roles can hinder the acceptance of robotic systems [22]. Addressing such concerns requires more than technical refinement: regulatory clarity, comprehensive training, and transparent communication about system capabilities and limitations are considered essential [21,22,59], with particular emphasis on framing robotic systems as supportive rather than substitutive.

The findings related to the GAToRS clearly differentiate between societal and individual levels. The subscale S+ reflects an abstract acknowledgment of the potential societal benefits of assistive robotic systems within the surveyed sample. However, S+ is not significantly associated with the evaluation of the developed service robot or with the individual intention to use it. This dissociation may suggest that an intellectual consensus on the societal benefits of robotics is not sufficient to translate into concrete behavioral readiness within the everyday practice of nursing.

In contrast, S– exhibits a substantially stronger association with the evaluation of the service robot. The subscale is significantly negatively correlated with the perceived usefulness and accessibility of the system and positively correlated with skepticism. Similar to S+, S– does not exert a direct influence on the individual intention to use. However, this asymmetry between S+ and S– may reflect a negativity bias, whereby societal-level concerns impair specific perceptions of the robot, while positive societal-level attitudes remain largely ineffective in shaping individual evaluations [60]. Accordingly, implementation strategies should not only emphasize potential benefits but also proactively address negative societal narratives—for example, through transparent communication that highlights the robot's role in supporting nursing staff, as well as clear information on potential risks and the corresponding safety measures [59].

At the individual level, a contrasting pattern emerges. P+ is positively associated with perceived usefulness and accessibility of the service robot, and also correlates with a stronger intention to use. As expected, nursing staff who reported a generally favorable disposition toward robotics evaluated the developed service robot more positively and demonstrated a higher intention to use it in future practice.

Although scores on P– were generally low in this sample, the subscale showed a significant positive correlation with skepticism. However, no significant associations were observed with usability, perceived usefulness, accessibility, or intention to use. Once again, an asymmetry becomes apparent. While positive dispositions are associated with more favorable evaluations across multiple outcome variables, negative dispositions are primarily linked to increased skepticism. Notably, this asymmetry contrasts with the pattern observed at the societal level, where negative attitudes exert a broader influence. In this sense, the expected negativity bias appears attenuated at the individual level, suggesting that favorable personal attitudes toward robotics may be more impactful in shaping evaluative outcomes than negative ones.

In summary, the data suggest that societal-level attitudes (S+ or S–) may shape the broader cognitive context in which robotic systems are perceived, whereas individual-level factors (P+ or P–) and concrete user experiences are ultimately more decisive for actual readiness to adopt such technologies. From a practical perspective, these findings underscore the importance of proactively counteracting negative societal narratives surrounding robotics—especially by addressing concerns about job displacement and by ensuring transparent communication of potential risks and existing safety measures, particularly those concerning care recipients [21,41]. In addition, positive individual experiences with robotic systems should be facilitated at an early stage, for example, through hands-on sessions or pilot implementations at the ward level [5,41]. A combined approach that integrates risk-sensitive communication with experience-based benefit framing constitutes a promising strategy for fostering the acceptance of service robots in nursing practice.

Another noteworthy observation is the unexpectedly limited influence of prior experience with robotics on the intention to use the developed service robot. In contrast to previous studies that describe prior exposure as a facilitator of technology acceptance [31,38,44], the present results show no statistically significant differences in the evaluation of usability, usefulness, skepticism, accessibility, or intention to use. Although minor trends in the expected direction were observable, the absence of significant group differences may be attributable to several explanatory factors, including structural characteristics of the research and development project and aspects of its methodological implementation. First, the user-centered and participatory development process likely enhanced the system's

XSL•FO
RenderX

approachability across experience levels. The continuous involvement of nursing staff throughout the design and refinement phases may have resulted in a solution that is intuitively operable, useful, and closely aligned with everyday nursing practice—even for users without prior exposure. Second, the selected application scenarios should have addressed tasks that are broadly accepted and perceived as meaningful within the professional nursing context. When the service robot's intended use is seen as relevant and beneficial, prior technical familiarity may become less decisive for acceptance. Third, the standardized, hands-on training provided to all participants ensured a uniform introduction to the system and likely helped reduce disparities in user confidence and system understanding. As a controlled intervention, this training could have mitigated differences in prior experience, thereby contributing to a more consistent evaluation of the system across groups.

These considerations indicate that a lack of prior experience does not necessarily constitute a major barrier to acceptance, especially when supportive conditions are present. Such conditions may involve user-centered system and scenario design that enables experience-independent access, along with targeted training efforts to reduce uncertainty and strengthen user competence.

Limitations

The interpretations of these findings are informed by methodological considerations. The sample size of 30 participants was adequate for an exploratory study and allowed for the identification of relevant patterns. However, it inherently limits the generalizability of the results. Subtle effects, such as potential associations with prior robotic experience, may not have been captured.

Additionally, a potential selection bias cannot be ruled out. Given that participation was voluntary, individuals with a greater affinity for technology may have been overrepresented, which could have contributed to a more favorable evaluation of the developed service robot. While such bias cannot be entirely avoided in applied research, it should be considered when interpreting the observed positive ratings.

Furthermore, the controlled laboratory setting, while beneficial for standardization and internal validity, only partially captures the complexity and situational variability of everyday nursing practice. Similarly, the relatively brief interaction period with the service robot prevents conclusions about sustained use or long-term integration into professional routines.

While acknowledging the study's limitations, this paper lays a foundation for future research by demonstrating the system's readiness for field testing and offering valuable insights into the factors influencing nursing staff's acceptance of service robots.

Conclusion

This study investigated a service robot developed to support routine tasks in inpatient care. A total of 30 nurses tested the system in 3 application scenarios (information service, item delivery, and beverage delivery), alternating between the roles of nurse and care recipient. Overall, the robot was evaluated positively, with high ratings for usability and perceived usefulness, low levels of skepticism, and moderate accessibility. The reported intention to use the system was high, indicating a substantial level of acceptance and a likely readiness for practical use in the tested application scenarios. The findings thus confirm the relevance of both the selected scenarios and the robot's potential to support these tasks.

The significant correlations observed between acceptance-related dimensions and the intention to use underline the necessity of a multilayered strategy that extends beyond technical optimization. User-centered design processes, transparent communication regarding system capabilities and limitations, as well as opportunities for personal orientation and hands-on experience, are essential to align robotic systems with the practical requirements, expectations, and concerns of nursing staff.

As the field of robotics in nursing advances, these aspects should be systematically integrated into future research, development, and nursing education. Ultimately, such an approach is essential to ensuring not only that the deployment of service robots in nursing is technically feasible but also that their potential to alleviate the physical and cognitive burden on nursing staff is fully realized, thereby enabling their effective and sustainable integration into the future of nursing practice.

Acknowledgments

The authors would like to thank all study participants for their time and valuable contributions, as well as Kim Klüber, Carolin Heizmann, Dr Peter Remmers, Claudius Lotz, and Prof Dr Linda Onnasch for their support in conducting the study. The authors also thank Dr Diana Rothe and her team at pi4_robotics for their technical support throughout the study.

Regarding the preparation of the manuscript, ChatGPT based on GPT-5.2 was used solely for linguistic refinement of text drafted by the authors. It was not used to generate scientific content, analyses, interpretations, or conclusions. The authors take full responsibility for the final manuscript.

Funding

The German Federal Ministry of Education and Research funded this research within the project "*Roboterunterstützung bei Routineaufgaben zur Stärkung des Miteinanders inPflegeeinrichtungen*"—grant number 16SV8436.

Abstract

Background: Global nursing shortages require innovative care delivery models. Virtual nursing is a cutting-edge model being explored.

Objective: This study aimed to examine the perspectives of clinical and administrative staff involved in a virtual nursing pilot on a medical-surgical unit and to identify best practices for future adoption.

Methods: We conducted a qualitative evaluation using individual semistructured interviews with virtual and bedside nurses, nurse executives, and IT project managers implementing a virtual nursing pilot program at a medical-surgical unit with 35 private and semiprivate beds at the Mount Sinai Hospital, a 1110-bed acute care hospital in New York, NY. Interviews took place in the spring of 2024 and were completed via phone or Zoom, audio recorded, and professionally transcribed. Participants were selected using purposive sampling. The authors applied an iterative thematic analysis to transcripts using Dedoose. Claude.ai was used to generate code summaries for select codes.

Results: Of 33 individuals approached, 16 (48.5%) consented to participate. Nine participants were clinical staff (virtual and bedside nurses and nurse managers), and 7 were executive leaders or managers in nursing and informatics. Our analysis identified the following themes: (1) staff attitudes toward virtual nursing shifted from resistance to acceptance over time, (2) direct communication channels between virtual and bedside nurses were critical for efficient care coordination and model adoption, (3) admission and discharge processes evolved throughout the pilot implementation, and (4) adaptable staffing allocations were necessary to accommodate fluctuating patient census and unit demands.

Conclusions: The main beneficiaries of this intervention, bedside nurses, found their virtual counterparts helpful following a few adjustments. Participants reported a perceived reduction in administrative burden, uninterrupted completion of clinical tasks, and they felt their overtime was reduced, which all increased their buy-in for this care model. There are several opportunities for improvement, such as real-time communication, unit-specific virtual nurse training, and flexible staffing for high-volume units. Our findings suggest that virtual nursing can address staffing challenges. Calculating the true return on investment for virtual nursing programs will require comprehensive mixed methods evaluations of such outcomes as care team and patient satisfaction, length of stay, readmission prevention, completion of nursing tasks, and reduction in overtime.

Introduction

Technological advancements, staffing challenges, and evolving patient expectations are driving a digital transformation that is rewriting how we deliver health care. The COVID-19 pandemic accelerated the adoption of electronic communication platforms to help reduce the spread of the deadly virus. A workforce crisis has emerged globally with the United States facing a shortage of between 1.8 and 3 million nurses according to different projections [1,2]. The excessive workload placed on existing health care personnel has resulted in heightened stress, burnout, psychosomatic disorders, anger, and anxiety [1]. To address this challenge, health care leaders are exploring a variety of digital health tools and integrated care models. The use of telehealth for outpatient visits increased 38 times in the first 2 years of the pandemic [3]. The use of digital tools also increased in the inpatient setting [4]. The majority of these interventions have involved a physician connecting with a patient or bedside staff (a nurse) in a patient's home or a clinical setting [5,6].

The pandemic's toll on the health care workforce, nurses in particular, has put new pressure on hospitals to identify nursing tasks that could be completed remotely. Among these are administrative tasks such as admissions and discharges [7], patient education [8], and 1:1 sitting [9]. Of these, virtual sitting for fall prevention has the most evidence, with 12 studies conducted between 2009 and 2021 [9]. Using virtual nurses for admissions and discharges is more recent, with only three virtual nursing pilots on the topic published to date [7,8,10]. Other formats of virtual nursing have also been explored. For example, colleagues from the Mayo Clinic reported on an inpatient virtual registered nurse (RN) program, in which experienced nurses (often retired or nearing retirement) provided guidance to bedside RNs and proactively monitored patients, with no difference in patient safety and care outcomes [11,12].

In a collaborative effort to address staffing challenges and improve patient care, the Mount Sinai Hospital (MSH) partnered with Banyan Medical Solutions, a third-party vendor, to implement a virtual nursing platform on a selected inpatient unit. The implementation process involved installing compatible large-screen smart TVs, wall-mounted cameras, and pillow speakers, enabling virtual nurses to perform critical roles such as patient education, admissions, and discharges. This qualitative research study aimed to examine partner perspectives on this virtual nursing pilot at MSH with a focus on operational implementation and to identify best practices and recommendations for further refinement.

Methods

Setting

In January 2024, a virtual nursing pilot was initiated at a 35-bed medical-surgical unit at MSH. The fast-paced unit with high daily discharges accepts various postoperative patients. Virtual nurses, credentialed by the state but working remotely from a command center, have full access to the hospital's electronic health records. These nurses joined the company in 2021 2022, are relatively junior with experience in other settings, and chose virtual work for personal reasons. Privacy protocols included "virtual knock" protocol, verbal consent requirements, and headphone availability for patients in semiprivate rooms.

Study Design and Sampling

We conducted a qualitative study using semistructured interviews to examine staff and leaders' perspectives and experiences related to the virtual nursing pilot program. We used purposive sampling to recruit participants from diverse professional backgrounds, aiming to gain a comprehensive understanding of the program from the frontline to leadership viewpoints.

Recruitment and Participants

Between February and June 2024, we invited 33 individuals to participate through email outreach, in-person shadowing, distributing flyers in common areas, and collaborating with hospital leadership. Data saturation was reached after completing about two-thirds of the nurse interviews, when new interviews yielded little additional information, following accepted standards in qualitative research [13]. We continued to recruit nonclinical personnel to ensure diverse perspectives.

Data Collection

Semistructured interviews were conducted via Zoom using a MSH account, lasting about 30 minutes each. Topics included patient and staff safety, privacy, technology reliability, program acceptability and usefulness, and improvement opportunities. The interview guide was developed based on research team discussions, particularly input from nursing leaders attuned to staff hopes and expectations. Our interview guide did not specifically explore formal clinical governance structures, focusing instead on operational implementation experiences. Using an interview guide helped ensure consistency and reliability of collected data across participants [14]. Interviewers (JR, MB, KG) used probes for clarification and conducted clinical shadowing (JR, MB) with field notes.

Data Analysis and the Use of Artificial Intelligence

Interview data were professionally transcribed and analyzed using iterative thematic analysis [15]. The team used Dedoose [16] for data analysis and management, and Claude.ai [17] to generate drafts of data summaries for selected codes. Three researchers (KG, MB, JR) read and coded the transcripts manually, using both deductive and inductive codes, refining codes through weekly discussion. Two coders applied the final codebook to each transcript in Dedoose. Major codes included care coordination, impact on workload, opportunities for improvement, and inclusion in decision-making. Minor codes included staff satisfaction, timing, best practices, and limitations of virtual nursing. After coding, the team identified key themes, downloaded relevant excerpts, and used AI to generate comparative summaries for each subtheme. Three analysts (KG, JR, MB) combined, iterated, and edited these summaries to create drafts of Results sections for further team refinement.

Ethical Considerations

The study was determined to be exempt by the Program for Protection of Human Subjects at the Icahn School of Medicine at Mount Sinai on January 17, 2024 (STUDY-23-01378). Informed consent was obtained after the nature and possible

XSL•FO
RenderX

consequences of the study were explained. The study adhered to local, national, regional, and international law and regulations regarding protection of personal information, privacy, and human rights. The study was deemed exempt by MSH's Human Subjects Protection Program, with all participants consenting to be interviewed and recorded, and receiving a US $25 gift card as compensation.

Results

Participants

Of the 33 individuals invited, 16 (48.5%) staff members consented and completed interviews (Table 1). The participants included 9 clinical staff (RNs, nurse managers, and virtual nurses) and 7 nonclinical personnel (executives in nursing and informatics, and IT managers). Based on the analysis of the data, we identified the following 4 major themes: (1) staff attitudes toward virtual nursing shifted from resistance to acceptance over time; (2) direct communication channels between virtual and bedside nurses were critical for efficient care coordination and model adoption; (3) admission and discharge processes evolved throughout the pilot implementation; and (4) adaptable staffing allocations were necessary to accommodate fluctuating patient census and unit demands.

[a]MSHS: Mount Sinai Health System.

Theme 1: Implementation Process: Staff Perspectives Adapt From Resistance to Acceptance

The implementation of virtual nursing revealed a clear evolution in staff attitudes, moving from initial skepticism to overall acceptance. Some of it had to do with the timing and depth of staff involvement in virtual nursing implementation decisions. Staff accounts indicate early concerns about role displacement and workflow disruption (Table 2, example 1a), which were exacerbated by the fact that early-stage participation was limited and staff were brought in late in the planning process. Staff identified missed opportunities for leadership to proactively engage frontline workers: "I would have loved to have had that interaction with Banyan earlier, because we had a bunch of questions that our people didn't have answers to" (Bedside RN, CL01; Table 2, example 1b). This delayed engagement led to accumulated questions and uncertainty among staff, though many issues were eventually resolved through concentrated information sessions. Nurse participants also reported that once the training was complete, they were relieved and realized that virtual nurses could be helpful (Table 2, example 1c).

XSL•FO
RenderX

Table . Key themes and representative quotes from participant interviews. Theme 1: Implementation process.

Example No.	Subtheme	Quote and participant role, ID
1a	Initial fears	“So there was a lot of trepidation. what is this actually going to look like. like physically how are they going to do this? And they’d be like, oh, we’ll get back to you.” (Bedside RN, CL01)
1b	Staff involvement	“.if the leadership is like. we’d like to go talk to the staff before we officially decide this so that we can let them know exactly how this works, maybe they’ll be a little bit more comfortable with it” (Bedside RN, CL02, Table 2, 1b).
1c	Relief	"We were thinking it was going to be a thing that we would have to worry about. But once you know all you have to do is a few clicks in the Banyan board, then I think that is definitely really helpful.” (Bedside RN, CL03)
1d	Decisions made at leadership level	“Because we are a union hospital, we did have to be very specific. That came from the CNO and the union.” (Nursing executive, NCL06)
1e	Leadership and change management	"It requires multiple conversations and sessions in advance of the model being implemented for people to first understand why we’re doing this. It's not for the heck of it. It's to help you" (Nursing executive, NCL07)
1f	Peer-to-peer learning	"I think if also there was an opportunity for people from [our unit] to go talk to the other units about it and how it worked, like to hear from peer-to-peer, that would be really helpful" (Bedside RN, CL03).

Several bedside nurses noted they wanted to be involved in technology evaluation and workflow decisions. This, however, was not always possible, as we learned from the interviews with nursing executives and nurse managers. One consideration was that the union leaders’ agreement on what tasks would be delegated to virtual nurses. Union considerations shaped decision-making authority, with decisions made at the leadership level (Table 2, examples 1c and 1d).

Our analysis also demonstrated real-world challenges in achieving meaningful staff participation while maintaining unit operations. Leaders described efforts to include staff while acknowledging limitations: "We do pull nursing staff off the floor to assist with any projects to get their insight, but we often know that they’re not able to stay every time for the whole hour, if at all” (Executive leader, NCL06). This resulted in a selective approach to staff involvement, with few staff members being able to go onsite to another hospital to observe Banyan operations.

During interviews, leaders emphasized their commitment to address staff concerns and support adoption of the new system. As one operations leader explained, "I would do anything I could to get leadership to the unit, to recognize that we appreciate you... we’re doing this as a resource for you” (Executive leader, NCL04). The implementation process required careful messaging and consistent support (Table 2, example 1e).

Finally, peer influence played a crucial role in shifting perceptions, particularly as floating nurses shared positive experiences across units: "When we get nurses from other units that float to us, they’re like oh my god, this is amazing. They all love it” (Bedside RN, CL06). Initial resistance transformed through hands-on experience and peer testimonials, with staff gradually recognizing virtual nursing as supportive rather than replacement technology (Table 2, example 1f).

Theme 2: Optimizing Technology Integration: Opportunities and Best Practices

System reliability and integration emerged as critical factors in implementing a virtual nursing platform. Here we describe *several operational opportunities for improvement* that can be used to establish best practices for implementation. These included technical integration to eliminate delays in communication, resolving audio quality issues, remote printing capability for virtual nurses, and volume control in shared rooms. These technical challenges collectively highlight the importance of robust infrastructure and seamless integration between systems for optimal integration into operational workflows.

Integration with existing hospital systems presented ongoing challenges. Multiple nurses noted issues with electronic health record connectivity and documentation access. These integration issues required bedside staff to navigate between multiple platforms, creating workflow inefficiencies (Table 3, example 2a). Bedside nurses desired a more nuanced communication tool with their virtual nurse partners in which they could specify discharge timing, for example, when transportation for the patient was already prearranged, and a direct communication

XSL•FO
RenderX

line between virtual nurses and providers. This highlighted the need for systems that could accommodate real-time coordination between virtual and bedside teams.

Table . Key themes and representative quotes from participant interviews. Theme 2: Optimizing technology integration.

Example No.	Subtheme	Quote and participant role, ID
2a	Systems integration	"Opening a separate screen, it sounds crazy, but it's often a pain... We basically have to open up a separate page. We have to go out of our Epic and open up a separate page to move Banyan." (Bedside RN, CL04)
2b	Audio quality	"It's loud... depending on the age group, depending on how sedated the patient is... Some of it is a [local] issue, that some of the TVs aren't coming through the call bell." (Bedside RN, CL04)
2c	Printing connectivity	"...if [virtual nurses] have completed all the discharge… it's just… one extra button to print it. Whereas if we have to print it, we have to go in, we have to look at all the things, then print it, and then gather it again. So it just saves a couple extra minutes with it being like oh, you're already in that section, you press the button." (Bedside RN, CL02)
2d	Patients with special accommodations	"So at that point I would probably do the interpretive services myself in person because on top of it that there's a new barrier of virtual, we have to then find an interpreter, and then we have the technology issues of whether the phone in the room is actually working... But even when it is working, I've seen that admission, instead of taking probably like a half an hour, it takes like over an hour." (Bedside RN, CL05)
2e	Workarounds	"And they themselves, taxi services, most of the time they're rude… they're like no, if they're not here in the next two minutes I have to leave and pick up the next person. They don't care. And then we're like let's just do the discharge ourselves and let's just… like let's not even wait for transport, let's just roll the patient down in the wheelchair on our own before they lose their taxi." (Bedside RN, CL05)

The interoperability challenges between the virtual nursing platform and the hospital's EHR system affected *care plan documentation and continuity*. Virtual nurses documented within both the Banyan system and Epic, but the lack of seamless integration meant that care plan updates were not always immediately visible to bedside staff without actively switching between systems. When virtual nurses completed admission assessments or discharge education, bedside nurses reported needing to actively seek out these updates rather than receiving automatic notifications of completed tasks. Remote printing connectivity for virtual nurses represented another technical hurdle. Bedside nurses explained that efficiency could be gained through improved printing functionality (Table 3, example 2c). According to one nurse, "it just saves a couple extra minutes… [if] you're already in that section, you press the button" (Bedside RN, CL02). While virtual nurses tried to send paperwork to print locally on the unit, this functionality did not work at the time of the interviews, making bedside nurses sign into the electronic medical record each time for the (virtually) discharged patient, find all the information, and send it to the printer again.

Audio quality issues particularly affected patients' willingness to accept a virtual nurse and staff efficiency, with problems being more pronounced during night shifts. Volume control concerns in shared rooms further complicated the situation, creating potential privacy issues and patient dissatisfaction, highlighting the need for better audio privacy solutions such as mandatory headphone use or room-specific volume controls (Table 3, example 2b).

While adaptations in the virtual nursing program showed promise for standard patient interactions, additional complexities arose with specific patient populations. Extended processing times for patients requiring interpreter services emerged as a particular challenge. Our bedside nurse participants reported foregoing virtual support altogether to save time and ensure effective communication with patients who needed interpreter services (Table 3, example 2d).

In response to these challenges, staff developed various *workarounds* to maintain efficient patient care. For example, bedside nurses described how transportation constraints sometimes necessitated bypassing virtual nursing protocols.

XSL•FO
RenderX

One nurse explained that taxi drivers often gave ultimatums about immediate departure, stating they would leave if patients weren't ready. This led staff to expedite discharges independently rather than risk patients losing their transportation (Table 3, example 2e). This adaptive approach allowed staff to balance the benefits of virtual nursing with practical operational needs. Another workaround—the implementation of Epic's secure chat functionality—marked a significant improvement in real-time coordination, with staff reporting it helped them coordinate plans with their virtual counterparts. Developing clear communication protocols, particularly for urgent situations, proved essential for maintaining seamless patient care across virtual and bedside teams.

IT specialists in our study highlighted the importance of technical considerations, such as future *interoperability*, beyond the immediate virtual nursing pilot. One IT leader pointed out that it is important to consider the use/reuse of technology components, such as smart TVs, for new nursing workflows that could be covered remotely: "how do we utilize a single or a smaller set of devices?" (NCL03). This perspective underscores the importance of strategic planning for technology integration that considers both current needs and future applications.

Theme 3: Care Coordination: Benefits of Virtual Nursing on Teamwork

The implementation of virtual nursing transformed admission and discharge processes, creating new team dynamics between bedside and virtual nurses. This theme explores how these workflows evolved and the benefits that emerged from this collaborative approach.

Transformation of the Discharge Process

Before the virtual nursing pilot, discharges required bedside nurses to manage multiple competing priorities simultaneously. One nurse described the traditional discharge process prior to the virtual nursing pilot implementation that involved educating patients, who were often frightened, about their discharge, trying to be supportive, "all while maybe a call bell's ringing, you're trying to get somebody their meds, you're hopefully not getting an admission because your workload is full" (Bedside RN, CL04; Table 4, example 3a). With the introduction of virtual nursing, the process became more streamlined. The same nurse explained that now they just switch a certain setting and "Banyan will often just start doing the discharges" (Bedside RN, CL04), freeing bedside staff to perform other tasks.

XSL•FO
RenderX

Table . Key themes and representative quotes from participant interviews. Theme 3: Care coordination.

Example No.	Subtheme	Quote and participant role, ID
3a	Old workflows (previrtual nursing)	"…prior to Banyan, you waited for a discharge order… You printed out your paper and we went to the bedside… we're a postsurgical unit, many people are absolutely frightened about going home with a new hip… and you would spend a tremendous amount of time educating, and teaching, and explaining their discharge. Then we wait for transport. And this is all while maybe a call bell's ringing, you're trying to get somebody their meds, you're hopefully not getting an admission because your workload is full." (Bedside RN, CL04)
3b	Good catch	"The only time I remember that it didn't go well is we had a patient who needed… [Lovenox] education... And the only way I was able to figure that out is because he was leaving and then his wife came up to me and she was like we never got the Lovenox education… So I think the nurse should have picked it up, like oh, you're going home on Lovenox injection, do you know how to administer it?.. He could have just walked out, went home, and not know how to do it. Good thing his wife [asked]… And I was like oh, okay, let's go back into the room and we will go through the steps on how to administer the Lovenox injection." (Bedside RN, CL06)
3c	Division of patient education responsibilities	"Especially with our ortho patients, they are usually prescribed a certain blood thinner so that they don't develop any clots, and if they're already taking blood thinners at home, and there's an issue with the medication or any interaction, they could definitely help somebody, you know, prevent them from having an adverse reaction..." (Bedside RN, CL05) "The hands-on teaching, plus the discharge, can take a long time. So for the discharge paperwork to be reviewed, and then I come in and just have to do Foley teaching, for example, with the leg bag, that just takes a lot of time off of my plate for me to focus on other things." (Bedside RN, CL03)
3d	No direct communication with providers	"[Virtual nurses] are not able to communicate with the frontline providers, and if… the patient has any questions, and they can't answer, and then they'll message us, and then I have to message the doctor, and then I have to relay that information to the virtual nurse… So, you know what I mean, so she still has to go through me…" (Bedside RN, CL06)

The discharge process transformation remains a work in progress, particularly regarding the division of educational responsibilities between virtual and bedside nurses. This was evident when a patient nearly left without critical Lovenox self-injection education, discovered only when his wife proactively inquired as they were leaving (Table 4, example 3B). Following this learning opportunity, the nurse implemented a new protocol of personally reviewing the After Visit Summary before handoff, proactively identifying teaching responsibilities that fall within the bedside nurse's scope rather than the virtual nurse's capabilities, thus ensuring patients receive all necessary education before discharge.

Emerging Communication Patterns and Task Coordination

As the unit grew more comfortable with virtual nursing, new communication patterns emerged between bedside and virtual nurses. Bedside nurses noticed that virtual nurses began to proactively update them on task completion. Virtual nurses reported developing strategies for prioritization through communication with bedside staff. As one virtual nurse explained: "Communication is key. You just let the bedside nurse know what's going on… could you please… let us know the order that you want us to prioritize the patients, whose transportation is coming first… It makes all the difference in

XSL•FO
RenderX

care" (Virtual RN, CL08). Virtual nurses reported initial lack of clarity about their role among patients, with one participant noticing an improvement in that respect: "the patients [are] just being educated more… regarding our services" (Virtual RN, CL07).

The division of educational responsibilities between virtual and bedside teams emerged as a key strength of the program. The system proved particularly valuable for complex cases, including newly diagnosed patients requiring extended education sessions. One bedside nurse highlighted the importance of virtual nurses' role in patient education, particularly for high-risk patients. She explained how orthopedic patients on blood thinners need to have their medications at home reviewed in case they were already taking blood thinners to prevent any interactions or adverse reactions (Table 4, example 3c).

A gap that remained unresolved at the time of the interviews had to do with virtual nurses' inability to message providers. For example, if a patient had a question during discharge that the virtual nurse could not answer, they had to message a bedside nurse who would then message a provider and report back to the virtual nurse who would relay it to the patient (Table 4, example 3d). Being unable to communicate directly with providers made this process unnecessarily involved and inefficient.

Time Efficiency and Focus on Direct Patient Care

A significant benefit reported by bedside nurses was how virtual nursing saved them time and allowed them to focus on hands-on teaching and direct patient care. One bedside nurse mentioned that discharges traditionally could take up to an hour and were now taken care of by their virtual counterparts (Table 4, example 3c). Another nurse echoed: "We're not stuck in a room for an hour doing admission questions and then having four other patients call on the Vocera and then get interrupted, going back and forth. That's what was happening before" (Bedside RN, CL06).

The ability to handle multiple tasks simultaneously was particularly valuable during busy periods. As one nurse explained: "Because if you're getting two admissions and you have a discharge, it's just a lot… So it's really helpful because then you're able to actually focus on hands-on patient care as opposed to…the paperwork aspect of it" (Bedside RN, CL03).

Improved Nursing Satisfaction and Work-Life Balance

The collaboration between virtual and bedside nursing staff resulted in positive outcomes for staff satisfaction and work-life balance. One nurse remarked, "It's nice to just like have that thought taken off your plate, as well as the admissions, just not having to stay late to do an admission when they come at… poor timing." (Bedside RN, CL02). Overall, the evolution of teamwork between virtual and bedside nurses created a more efficient workflow for admissions and discharges, allowing nurses to dedicate more time to direct patient care while ensuring comprehensive education and documentation.

Theme 4: Timing Is Key: Staffing Capacity and Patient Flow

Workflow integration and staffing alignment emerged as critical factors in the uptake and efficiency of virtual nursing, revealing the importance of proper coordination between virtual and bedside teams in managing patient flow.

Managing High-Volume Patient Movement

The partnership between virtual and bedside teams impacted patient workflow management, particularly during high-volume periods. One bedside nurse explained that their unit had "a colossal amount of movement… [with] 14 to 20 [daily] discharges and admissions" (CL04). Effective workforce distribution proved essential for managing such volume, as staff needed to adapt to fluctuating demands throughout the day. As another bedside nurse explained: "Sometimes they could say 10 [discharges], so they have, let's say, 5 [virtual] nurses on board, but then as the day goes on, the discharges do happen, so instead of having 10 we'll have 18" (Bedside nurse, CL06). This unpredictability highlighted the ongoing need to develop flexible staffing management strategies that could respond to rapidly changing conditions. Ascertaining the right staffing levels for virtual took some tweaking, as is evidenced by one bedside nurse report about initial challenges during the overnight shift, when there was only one virtual nurse available (Table 5, example 4A).

XSL•FO
RenderX

Table . Key themes and representative quotes from participant interviews. Theme 4: Timing is key.

Example No.	Subtheme	Quote and participant role, ID
4a	Initial insufficient staffing	"…it also comes down to how many people, how many nurses is Banyan hiring for our unit per shift... Because the thing is, [my supervisor] said oh, we noticed that things are running slow. [The virtual nurse said] I'm sorry, I apologize, it's just [I am] the only nurse with them at that shift… That was when Banyan was first implemented… I actually think Banyan can work in a fast-paced, but if there's enough staff, virtual nurse staff, and also to make things run faster." (Bedside RN, CL05)
4b	Impact on hospital throughput	"Once we discharge this patient we can pull more patients coming from the PACU and from the ED, so it helps them, like don't hold the OR schedule nor have a critical diversion in the ED" (Bedside RN, NCL05).
4c	Nurses more readily accept admissions at end of shift	"I think now that we have the Banyan nurses, nurses are not... reluctant on taking the admission from PACU. They'll just pick up because they know that when they come onto the floor that they don't have to deal with these admission questions, that they're going to be taken care of" (Bedside RN, CL06).

Impact on Hospital-Wide Operations

The virtual nursing system's impact extended beyond individual patient care to affect broader hospital operations. The most positive impact of the pilot, as perceived by our participants, was what they described as improved patient throughput. During peak periods, virtual nurses supported bedside teams, creating capacity to process patient admissions and discharges simultaneously. High volume peaks required different coordination compared to slower-paced environments, while night shift operations needed special adaptations to maintain patient comfort and prevent disruption during quiet hours. According to one nurse, by facilitating more efficient discharges, the system improved patient throughput across multiple departments (Table 5, example 4b).

This improvement in patient flow was also reflected in staff attitudes toward accepting new admissions. Nurses used to be reluctant to accept an admission from PACU, for example, if it meant they would have to stay longer after the end of their shift to complete it. According to several participants, this was no longer the case (Table 5, example 4c).

Time Investment in Patient Education

Virtual nurses reported dedicating significant time to patient education, highlighting the value of this investment despite its potential impact on short-term throughput. One virtual nurse reflected on the depth of engagement required: "I would say I think I'm long with discharges personally… I take a while. They have so many questions… The family's in there, the mom, the dad. So yeah, I feel like my discharges are long, like an hour… I feel bad. Some of them are newly diagnosed, so that's even longer, like an hour and a half" (Virtual RN, CL09). This time investment, while potentially extending the discharge process itself, ultimately supported more comprehensive patient education and potentially better postdischarge outcomes, demonstrating that flexibility in staffing and timing considerations needs to balance efficiency with quality of care.

Discussion

Principal Findings

This is the first qualitative evaluation of a virtual nursing pilot on an inpatient unit. Our findings demonstrate that virtual nursing implementation requires careful attention to technological infrastructure, operational readiness, and change management. We identified four major themes that characterized the virtual nursing implementation in our pilot: (1) achieving staff buy-in takes time and can benefit from earlier engagement strategies; (2) seamless technology integration, especially direct communication channels, is critical for smooth operation; (3) recognition of virtual nurses as integral team members, rather than auxiliary support, enhances collaborative care delivery; and (4) virtual nursing coverage must meet the demand to maintain relevance within the organizational or unit context.

Our study offers insights into implementing virtual nursing on inpatient units, which other hospitals can use when considering similar models. The unique unit or patient population characteristics—high volume, fast pace, surgical patients with diverse diagnoses—fit well with the virtual nursing pilot seeing benefits in admission or discharge support and patient education. If virtual support was unavailable or inefficient, the bedside nurses reverted to their traditional workflows. With the exception of some initial issues, the vendor was able to meet the challenge and provide sufficient support. Virtual nursing implementation on slower-paced units might prioritize functions like virtual sitters, which could be particularly useful on observation units.

XSL•FO
RenderX

Our findings highlight the critical importance of seamless EHR integration for virtual nursing models. The fragmented documentation workflow we observed, where staff navigated between multiple systems, created inefficiencies that could impact care continuity. The care plan coordination issues, exemplified by the Lovenox education incident, demonstrate how documentation gaps can directly affect patient safety. Virtual nursing programs must establish clear protocols for documenting care plan handoffs, particularly for complex patients requiring both virtual and bedside interventions and prioritize robust interoperability that allows direct documentation within the primary care record.

Technical and system reliability directly impacted operation readiness. The integration between EHR and the virtual nursing platform, audio quality, and physical environment considerations influenced staff adoption and clinical workflows. Virtual nursing adoption hinges on infrastructure investment that could be a barrier for smaller hospitals.

The pilot used out-of-state junior RNs. Other staffing models could be considered, such as floating bedside nurses as virtual for a fraction of their time. Implementers should weigh the efforts needed to educate new virtual staff vis-à-vis managing virtual nursing in-house.

Flexible staffing in response to patient flow emerged as one of the most critical factors for optimal operation. Implementation followed an overall positive trend—initial increases in workload during rollout, followed by productivity improvements once frontline staff adapted to their new workflow. Participants reported positive downstream effects such as reducing operating room holds and emergency department diversions through improved time to discharge and bed turnover.

This pilot aligns well with the cutting-edge innovations in health care operations. Our findings demonstrate that implementation depends on structured approaches to change management [18] while minimizing disruption to care delivery. Key insights from our analysis—albeit not new [19]—reveal the importance of early staff involvement in the decision-making process.

Staff adoption of the virtual nursing platform followed a progression from initial skepticism to approval. Clinical champions were powerful influencers of technology acceptance. Clear role separation created effective partnerships, particularly in educational delivery. Virtual nursing could leverage experienced nurses' expertise post COVID-19 pandemic, like programs at other institutions have shown [11,12].

Limitations and Strengths

Our study has the following limitations. We interviewed hospital personnel but not patients or caregivers. Understanding how both patients and caregivers view this intervention is essential for improving it further. Researchers need to examine not just how the interactions between patients and virtual nurses are designed to work, but also how patients and caregivers actually experience and respond to these interactions. It is a single-center pilot study in an academic medical center; our findings might not apply to a different health care setting or patient population. With about a 50% response rate, a nonrespondent bias is possible. Our study did not include quantitative data on reduced overtime, improved throughput, or quality indicators such as patient satisfaction, medication errors, or readmission rates. All comments related to these important metrics were based on the impressions of bedside and virtual staff and executive leaders. We also did not systematically examine formal clinical governance models or committee structures that may have guided the implementation process, nor did we evaluate preimplementation preparation or formal support models during rollout. However, this is the first published qualitative study of virtual nursing programs to our knowledge, capturing valuable nurse and leadership perspectives through its qualitative approach.

Recommendations for Planning Virtual Nursing Implementation

Based on our findings, implementation of virtual nursing requires attention across several domains. Organizations considering adoption should prioritize early infrastructure investment, unit-specific workflow design, clear governance structures, and intentional patient-facing communication. The following checklist sums up key considerations to guide planning and implementation.

- Technical infrastructure
- Invest in technical and communication infrastructure upfront to ensure seamless system integration between virtual and bedside nurses and between virtual nurses and providers
- Develop or adopt AI tools to support automatic patient prioritization for admission and discharge

- Workflow
- Implement dynamic staffing allocations responsive to patient volume fluctuations
- Adapt and optimize workflows to reflect specific demands of each unit
- Develop clear standard operating procedures for communication between virtual and bedside staff
- Conduct regular review of staffing allocations based on utilization patterns

- Clinical governance
- Establish formal governance structures with designated clinical champions

- Patient-facing communication
- Use nurses' insights to create standard messaging on introducing the virtual nursing program to patients and setting expectations
- Develop privacy standard operating procedures for shared rooms, including headphone distribution and consent procedures for virtual interactions

Conclusions

Virtual nursing is a cutting-edge care delivery innovation that goes beyond adoption of new technology. This virtual team model enhances care coordination, patient throughput, and staffing while keeping care patient-focused. Program success requires resources, technical infrastructure, and clear, unit-specific communication. Health care should see it as bedside care extension, with careful planning and ongoing adjustments based on data and feedback.

XSL•FO
RenderX

This study provides valuable insights for hospital leadership and management to understand the impact on clinical workload, staff acceptability and satisfaction, and patient care quality to support informed implementation decisions. Future research should explore several questions that emerged during this implementation: (1) How do virtual nursing models impact nurse retention and recruitment in a high turnover environment? (2) How might AI integration enhance the efficiency of virtual nursing documentation and communication? (3) How do patients perceive virtual nursing and how can their experience be improved? (4) What does virtual nursing affect quality and safety outcomes such as patient satisfaction, readmissions, and medication errors? Addressing these questions will further develop the evidence for this emerging care delivery model.

Abstract

Background: Aging populations and rising chronic illness prevalences are increasing demands for nursing care, while staff shortages threaten care quality. Robotics offer potential support, yet usability, workflow integration, and user acceptance remain major barriers.

Objective: This study aims to develop and evaluate the feasibility, usability, and acceptance of a cross-device platform for controlling robotics in nursing using a participatory, user-centered approach.

Methods: A convergent mixed methods feasibility study was conducted across 4 iterative workshops with 13 nurses from 2 German health care facilities. Quantitative measures included the System Usability Scale (SUS), Technology Usage Inventory (TUI), and Technology-based Experience of Need Satisfaction (TENS-Interface). Qualitative data were collected via think-aloud protocols and focus groups. Data integration supported iterative platform refinement and assessment of usability, acceptance, and satisfaction of psychological needs.

Results: Participants exhibited high curiosity, perceived usefulness, and strong intention to use robotics, with low skepticism. SUS scores indicated acceptable usability. TENS-Interface scores showed increased autonomy and competence following workflow simplification and stepwise interaction logic. Qualitative findings emphasized intuitive control, personalized interventions, centralized management of multiple technologies, integration with documentation systems, and structured training. Triangulation of quantitative and qualitative data confirmed that iterative, user-centered refinements enhanced usability, acceptance, and platform effectiveness.

Conclusions: Cross-device platforms integrating robotics can be successfully developed through participatory, user-centered methods. Technical usability, personalization, workflow integration, and structured training are key for adoption. The study demonstrates that technological barriers, rather than human resistance, are primary constraints to integrating robotics into nursing practice and can be mitigated through iterative co-creation aligned with real-world care contexts.

Introduction

Background

Worldwide demographic shifts, including population aging and the increasing prevalence of chronic illness, are driving a growing demand for nursing care, while persistent shortages of qualified nursing professionals threaten the quality and availability of services [1-4]. Robotic systems have therefore been proposed as a promising strategy to support nursing care; however, their implementation in routine practice remains challenging [5]. According to International Organization for Standardization (ISO) 8373:2021 [6], a robotic system is defined as a programmable, actuated mechanism capable of performing physical tasks autonomously or semi-autonomously under the control of a control system. Through the integration of sensors, actuators, and control components, robotic systems can interact

XSL•FO
RenderX

with their environment and execute predefined or adaptive actions. This broad definition includes service and assistive robots used in health care settings, such as telepresence robots and mobile manipulators.

In nursing contexts, robotic systems have been shown to support psychosocial and rehabilitative processes, with reported benefits for emotional well-being, cognition, social interaction, and quality of life among older adults [7]. Robots are also used in rehabilitation and physical therapy as well as in psychosocial interventions [8]. Beyond direct patient care, robotic technologies can support organizational processes, including telepresence, virtual consultations, and the training of nursing staff, and can assist with logistical tasks such as transporting medication and materials, disinfection, and procedural support [9]. Despite these potential benefits, most robotic systems remain at early stages of development or testing, and only a limited number have been implemented in routine care settings [10,11]. Moreover, the high financial investment required for acquisition and maintenance continues to be a major barrier to widespread adoption [11].

Previous research indicates that the successful implementation and integration of robotic systems in nursing care depends not only on technical performance but also on user acceptance, contextual implementation processes, and the systematic involvement of end users throughout development and evaluation phases. International reviews and empirical studies consistently demonstrate that sociocultural, organizational, and user-centered factors play a decisive role in facilitating practical adoption, beyond the technical design of robotic systems alone [10,12,13].

Nursing staff generally report a willingness to engage with robotic technologies, driven by perceived benefits such as workload reduction, increased efficiency, and improvements in care quality [14,15]. However, many existing robotic systems do not adequately meet users' needs with regard to usability, adaptability to individual patient requirements, and integration into established care workflows [7,8,11]. In particular, a lack of intuitive interaction concepts and standardized, cross-device solutions often results in complex and inconsistent operation [8,16,17]. Furthermore, the absence of common standards for the external control of robotic systems remains an unresolved challenge [16,18]. Participatory development approaches, such as cocreation [19] and design-based research [20], have been shown to address these challenges by actively involving end users throughout the design process. Early and continuous stakeholder involvement not only improves system usability and acceptance but may also positively influence care processes and outcomes by aligning technological solutions with user needs and care contexts [21-24]. Nevertheless, robotic systems that provide simple, cross-device, and adaptable interaction concepts and that are co-designed directly with nursing staff remain scarce [24].

Objective

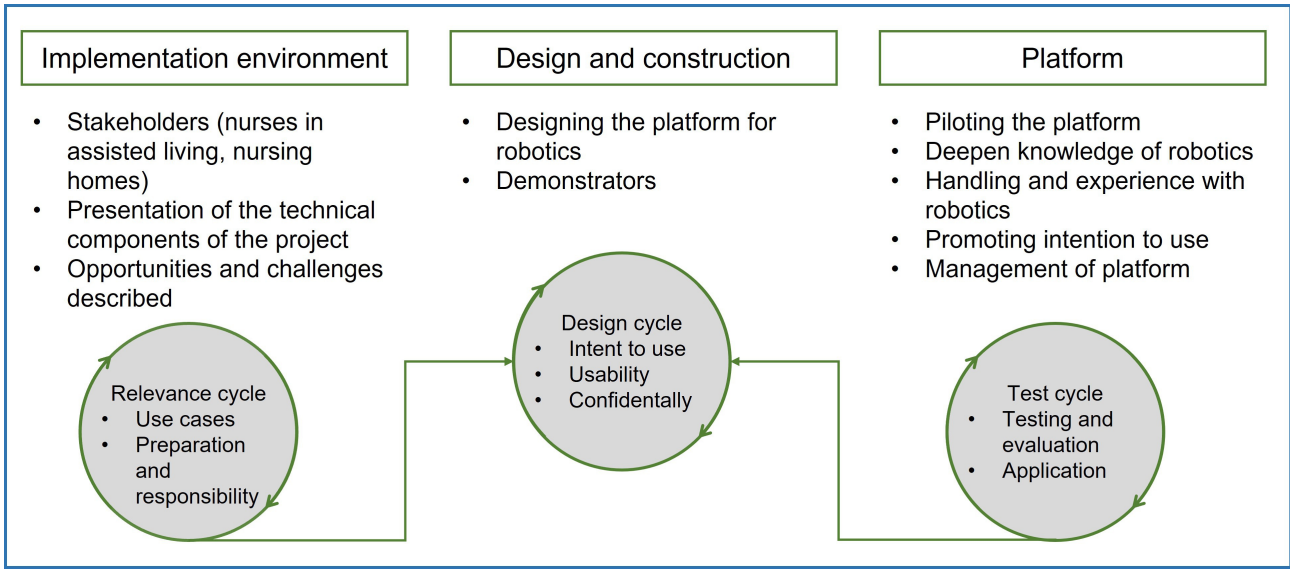
Robotic systems have the potential to support nursing practice; however, their uptake is limited by insufficient usability and limited adaptability to individual care needs. The Educational Exploration Robot Application Platform (EduXBot) project addresses this gap by developing a simplified and unified interface that enables nursing staff to operate existing robotic systems. The accompanying mixed methods feasibility study pursued two objectives: (1) primary objective: to assess the usability, technology acceptance, and user experience of the EduXBot platform among nursing staff within the framework of an iterative, user-centered design process and (2) secondary objective: to develop a multilevel benefit concept for the platform through an in-depth qualitative evaluation using think-aloud and focus group methods to identify perceived value and areas for further improvement.

Together, these objectives aimed to evaluate the platform's effectiveness and its potential to support the sustainable integration of robotic systems into nursing practice.

Methods

Conceptual Framework

The EduXBot project aims to develop an interaction and control platform that simplifies the use of robotic systems in nursing care. The development process follows a participatory and user-centered approach, explicitly incorporating the expectations, experiences, and practical requirements of end users throughout all phases of the project. This process fosters the development of innovative, practical, and user-centered solutions that are more likely to be adopted in everyday practice [25].



The development process was grounded in user-centered and cocreative principles that combine iterative engagement with end users and structured design cycles. Although Farao et al [26] described a user-centered framework that integrates iterative design and stakeholder engagement, our approach emphasizes active collaboration with end users throughout iterative prototyping, evaluation, and refinement phases consistent with cocreative design practices in participatory technology development.

This methodological approach supports the development of a tailored end product based on nurses' domain expertise while systematically considering potential implementation consequences [26-28]. Previous research has shown that cocreative and user-centered approaches can improve relevant outcomes and increase the usability and acceptance of technological systems in health care settings [29,30].

Figure 1 illustrates the integration of relevance, rigor, and design cycles to align nursing practice requirements, scientific evidence, and iterative platform development: the relevance cycle, which captures the realities and needs of end users; the rigor cycle, which draws on the existing scientific knowledge base; and the design cycle, which translates these inputs into the iterative development of the technical product [31-33]. Through this framework, requirements for the robotic systems addressed in the study can be systematically identified and practically operationalized. The close collaboration between researchers and end users further enables active user involvement in product evaluation, thereby supporting the functionality, usability, and overall success of the platform.

XSL•FO
RenderX

Figure 1. User-centered and cocreative design framework (adapted from Farao et al [26]).

Within this collaborative framework, EduXBot does not seek to develop new robotic hardware. Instead, it focuses on providing an extensible interaction and control platform for existing robotic systems. The platform is designed as a flexible and open system architecture that integrates diverse robotic, sensor, and interaction technologies into a unified interface. Its modular design allows nursing staff with varying levels of technological expertise to configure and use the system, thereby supporting a layperson-oriented approach to human-technology interaction. This design was developed in close collaboration with end users to ensure relevance and usability in nursing practice.

Study Design

An iterative feasibility study accompanied the development of the EduXBot platform. The study was conducted as a convergent mixed methods design in accordance with Creswell and Plano Clark [34], with quantitative and qualitative data collected in parallel and analyzed independently. Quantitative data were used to assess usability, technology acceptance, and the fulfillment of psychological needs, while qualitative data captured nursing staff's experiences, perceptions, and interaction processes. Following separate analyses, both data strands were integrated to enable a comprehensive interpretation of the findings and to inform the iterative development of the platform. This mixed methods approach aligns with a pragmatic research paradigm, in which methodological choices are driven by the research questions and support a triangulated understanding of the research problem.

Two health care facilities in Germany served as practice partners. Facility 1 was a long-term inpatient care facility. Facility 2 was a regional health center providing acute inpatient care, outpatient services, and long-term inpatient care. Both institutions had previously participated in technology-related research projects and agreed to collaborate in this study. Facility managers were informed about the project and asked to encourage nursing staff to participate.

Participants were recruited using purposive sampling with the aim of maximizing variation in age, gender, and professional experience, thereby capturing a broad range of perspectives relevant to the research topic [35]. The inclusion of nurses from diverse backgrounds enhanced the heterogeneity and informational value of the study sample. Participation was voluntary, and scheduling constraints or other commitments could limit participation or lead to withdrawal during the study.

Instruments

Quantitative Instruments

Surveys were administered at 4 measurement time points (T0-T3) during each development iteration and included the Technology Usage Inventory (TUI), System Usability Scale (SUS), and Technology-based Experience of Need Satisfaction (TENS-Interface). All instruments were administered as self-report questionnaires completed individually by each participant.

The TUI [36] assessed participants' intention to use robotic systems by measuring technology-related and psychological factors. For this study, the TUI was adapted to address robotic systems in general and was administered once per measurement point. We analyzed 7 subscales: curiosity, fear of technology, interest, skepticism, accessibility, usability, and usefulness. Higher scores indicate stronger expression of the corresponding construct, while lower scores indicate weaker expression. Scale sum scores were converted into stanine values ranging from 1 (well below average) to 9 (well above average).

The SUS [37] measured the usability of each technology integrated into the EduXBot platform. Collecting SUS scores for individual technologies allowed the identification of technology-specific usability issues, providing targeted feedback for iterative development. Medians and IQRs were aggregated to provide a generalizable estimate of the platform's overall usability, aligning the technology-level measurements with the study's primary focus on platform-level usability. Scores ≥68 were considered indicative of acceptable usability, supported by adjective-based interpretations from "outstanding" to "very poor."

XSL•FO
RenderX

The TENS-Interface [38] is a standardized questionnaire that assesses the extent to which a technology interface meets users' psychological needs (autonomy, competence, relatedness) in human-technology interaction. It was administered from T1 onward, when a prototype was available, and focused specifically on the interaction platform interface.

Qualitative Methods

Qualitative data were collected through think-aloud sessions and focus groups. During think-aloud sessions, participants performed predefined tasks for each technology, verbalizing their thoughts and experiences while interacting with the platform [39]. Standardized instructions ensured consistency, enabling systematic observation of interface interaction and usability. Sessions were audio-recorded and transcribed for analysis.

Focus groups were conducted after each workshop [40,41] to refine the platform iteratively. Participants discussed their experiences with the current prototype; evaluated its compatibility with daily care workflows; and identified unmet needs, usability barriers, and desired functionalities. Focus groups were guided by predefined questions, audio-recorded, and transcribed verbatim. Findings were systematically fed back into the design process and informed subsequent platform refinements.

Data Collection

Prior to the initial measurement (T0), a needs assessment workshop (Table 1) was conducted involving nurses, nursing scientists, and developers. Participants were introduced to existing robotic technologies and collaboratively generated potential application scenarios. Based on practical relevance and technical feasibility, 4 use cases were selected to guide the development of EduXBot prototypes:

1. Conversational partner: implemented via the Double3 telepresence robot, which recognizes residents by voice or face and can respond to personal preferences and topics
2. Telepresence: also using the Double3, enabling remote participants to communicate and engage in activities on site
3. Safe walking partner: implemented via the Go1 4-legged bionic robot, providing monitoring during walks and reporting falls
4. Record/playback of personal events: implemented using the PICO 4 virtual reality (VR) headset, allowing the recording and immersive playback of events such as family birthdays or facility celebrations, to support biographical work

Table . Overview of the 4 iterative workshops at the 4 measurement time points (T0-T3).

Measurement time point	Thematic focus	Use cases	Technologies	Instruments
T0	Define requirements	• Conversational partner • Telepresence • Record/playback of personal events	• Double3 • PICO 4	• TUI[a] original questionnaire (pre-post version) • SUS[b] • Think-aloud • Focus group
T1	Explore concept framework and interaction design	• Conversational partner • Telepresence • Record/playback of personal events • Safe walking partner	• Double3 • PICO 4 • Go1	• TUI II parallel questionnaire (complete version) • SUS • TENS-Interface[c] • Think-aloud • Focus group
T2	Testing the prototype for interaction design	• Conversational partner • Telepresence • Record/playback of personal events	• Double3 • PICO 4	• TUI II parallel questionnaire (complete version) • SUS • TENS-Interface • Think-aloud
T3	Test simplified step-by-step processes and integrated control	• Conversational partner • Record/playback of personal events • Safe walking partner	• Double3 • PICO 4 • Go1	• TUI II parallel questionnaire (complete version) • SUS • TENS-Interface • Think-aloud • Focus group

XSL•FO
RenderX

Data were collected at 4 time points (T0-T3), each corresponding to one iterative development cycle. Workshops followed a standardized structure and integrated evaluation of both the interaction platform and selected technologies. Depending on the development stage, not all technologies nor use cases were presented at every workshop. Table 1 summarizes the technologies and use cases tested at each workshop, along with the applied quantitative and qualitative instruments and thematic focus.

A prototype, defined as a preliminary version of a product or system used to evaluate and refine its key characteristics, design, and functionality prior to final implementation, was used throughout the study [42,43]. Participants interacted in small groups (up to 3 individuals) at station-based setups, rotating between stations to test the prototype and technologies available for that workshop. Usability was assessed at the individual level using the SUS immediately after task completion at each station, ensuring that responses reflected individual perceptions rather than group-based consensus.

After station-based testing, participants completed the TUI and TENS-Interface questionnaires independently and individually, capturing overall intention to use and psychological need satisfaction related to the platform. To minimize potential social influence, participants were instructed to complete all questionnaires independently, and no collective rating nor group agreement was requested at any point during data collection.

Each workshop concluded with a focus group discussion in which participants collectively reflected on experiences, workflow compatibility, usability barriers, and suggested refinements. Insights from think-aloud sessions and focus groups were systematically fed back into the iterative development process and informed subsequent platform and technology adaptations.

Data Analysis

Quantitative data were analyzed using SPSS version 28 (IBM Corp) [44]. Continuous variables are reported as medians and IQRs, and categorical variables are reported as absolute and relative frequencies. Missing data were handled using pairwise deletion.

Group differences in cumulative SUS and TUI scores at T3 were examined using 1-way ANOVA considering factors such as gender, qualification, and facility. Assumptions of normality and homogeneity of variances were tested, with the Welch correction applied if homogeneity was violated. Post hoc Bonferroni tests were planned but not conducted due to nonsignificant effects. Pearson correlations were calculated to examine relationships between usability (SUS), intention to use (TUI subscales), and psychological need satisfaction (TENS-Interface) at T3. Hierarchical regression analyses assessed predictors of intention to use, with SUS, TENS-Interface, and TUI subscales entered in blocks. Model assumptions (linearity, independence of residuals, homoscedasticity, multicollinearity) were checked prior to interpretation.

Qualitative data were analyzed using inductive content analysis following the method by Kuckartz and Rädiker [45] with MAXQDA version 24.10.0 (VERBI Software) [46]. Transcripts from think-aloud sessions and focus groups were initially coded independently by two researchers (PM, RV). Both methods addressed the same overarching research question—platform design and adaptation of use cases. Coding of the two data sources was therefore integrated in a single schema, enabling triangulation, consistent identification of emerging themes, and comprehensive interpretation across data sources.

Codes were iteratively grouped into subcategories and overarching categories through discussion until consensus was reached. The coding process included systematic comparison across iterations to capture the evolution of requirements, usability challenges, and user perceptions. Intercoder reliability was assessed using Cohen kappa coefficient.

Qualitative data collection was structured according to predefined iterative development cycles rather than aiming for theoretical saturation. The number and timing of think-aloud sessions and focus groups were determined by the 4 development iterations, with each workshop representing 1 iteration of platform refinement. Data collection concluded upon completion of the final iteration, ensuring that all planned prototypes had been systematically evaluated. Emerging themes and usability issues were continuously reviewed after each iteration and directly informed subsequent platform adaptations. This approach was chosen because the study's objective was to iteratively refine the platform in close collaboration with end users, rather than to achieve saturation of qualitative data.

Mixed methods integration followed a convergent design [34], incorporating both formative and summative integration of quantitative and qualitative data. Formatively, findings from think-aloud sessions and focus groups were continuously fed back into the iterative development process to refine the platform. Summatively, quantitative and qualitative results were triangulated, comparing and integrating findings across data sources to provide a comprehensive understanding of platform usability, technology acceptance, and practical value in nursing workflows. This triangulation allowed complementary perspectives, convergence, and divergence to be identified and interpreted in context.

Ethical Considerations

The study received ethics approval from the ethics committee of the Medical Faculty of Martin Luther University Halle-Wittenberg (approval 2023 - 190, August 31, 2023) and was registered at the German Clinical Trials Register (DRKS00034195). Written informed consent was obtained from all participants, and no financial compensation was provided. Data were collected anonymously to ensure participant privacy and confidentiality.

The methodological rigor of the study was ensured by adhering to the Good Reporting of a Mixed Methods Study (GRAMMS) checklist [47] and the Mixed Methods Appraisal Tool (MMAT) [48]. The comprehensive study protocol has been published elsewhere [49].

Results

Participants

Between February 2024 and May 2025, 13 nurses from 2 health care facilities participated in the study. Some nurses participated in multiple iterations, yielding a total of 33 participation units across the 4 development iterations. Participants could not be clearly categorized into core or ad hoc groups due to variable attendance; however, each nurse participated in at least 2 iterations.

Participants' age, gender, professional qualifications, and experience are summarized in Table 2. Age and professional experience were calculated at the time of each participant's first iteration to account for staggered entry. Professional experience was defined as years since completion of formal nursing education or training. Median age was 46 (IQR 10.5) years, and the median length of professional experience was 15 (IQR 13.5) years. Most participants held managerial nursing roles, supplemented by support staff and occupational therapists, providing diverse perspectives for assessing the integration of the platform into daily care routines.

Table . Demographic characteristics of participating caregivers at the 4 measurement time points (T0-T3).

Characteristics	T0 (n=8)	T1 (n=9)	T2 (n=8)	T3 (n=8)
Age (years), mean (SD)	45.6 (9.1)	47.8 (9.3)	50.1 (7.8)	48.3 (9.5)
Gender, n (%)				
Male	1 (12.5)	1 (11)	1 (12.5)	1 (12.5)
Female	7 (87.5)	8 (89)	7 (87.5)	7 (87.5)
Qualification, n (%)				
3-year duration of training	1 (12.5)	1 (11)	0 (0)	1 (12.5)
3-year duration with professional training	2 (25)	1 (11)	1 (12.5)	1 (12.5)
Nursing service management	3 (37.5)	3 (33)	3 (37.5)	3 (37.5)
Studies	1 (12.5)	2 (22)	2 (25)	1 (12.5)
Other qualification	1 (12.5)	2 (22)	2 (25)	2 (25)
Professional experience (years), mean (SD)	13.5 (9)	16.3 (10.8)	16.9 (10.8)	18 (10.5)
Facility, n (%)				
Facility 1	6 (75)	7 (78)	7 (87.5)	6 (75)
Facility 2	2 (25)	2 (22)	1 (12.5)	2 (25)

Quantitative Evaluation

Participants exhibited higher openness to robotics than the general population, as indicated by above-average TUI stanine scores relative to the normed reference population [36]. Table 3 presents TUI subscale scores including curiosity, fear of technology, interest, usability, usefulness, skepticism, and accessibility. Scores are reported as medians and IQR, with stanine values indicating relative positioning versus the normed reference population. Median intention to use at T0 was 255 out of 300 and remained stable across iterations. High scores were observed for curiosity (median 23 from a possible total of 28) and perceived usefulness (median 22 from a possible total of 28), whereas skepticism was low (median 9 from a possible total of 28). These results indicate general interest in and acceptance of robotics.

XSL•FO
RenderX

Table . Technology Usage Inventory (TUI) subscale scores at the 4 measurement time points (T0-T3).

TUI subscale	Max score	T0 score		T1 score		T2 score		T3 score	
		Median (IQR)	Stanine	Median (IQR)	Stanine	Median (IQR)	Stanine	Median (IQR)	Stanine
Curiosity	28	22 (6.5)	7	22 (9.75)	7	20 (7.5)	7	23 (9.25)	8
Fear of technology	28	9 (13.5)	5	7 (11)	4	7 (3.75)	4	10 (7.5)	5
Interest	28	18 (12)	6	23 (2)	7	24 (5.5)	7	24 (6.75)	7
Usability	23	18 (4.75)	6	14 (5.5)	4	14 (2.75)	4	17 (5.5)	6
Usefulness	28	22 (4.5)	9	24 (3.5)	9	24 (9)	9	22 (5.5)	9
Skepticism	28	7 (5.75)	2	9 (7.5)	3	10 (4.5)	4	9 (5.75)	3
Accessibility	23	11 (9)	6	11 (4)	6	11 (3.75)	6	11 (3.75)	6
Intention to use	300	255 (69.5)	8	246 (58.5)	7	254 (40.25)	8	262 (46.5)	8

SUS scores were assessed per technology and aggregated to evaluate overall platform usability (Table 4). Median and IQR are reported. Overall usability decreased slightly from “excellent” at T0 to “good” at T3 but remained within the acceptable range. Double3 usability improved over time, whereas Go1 and PICO 4 showed declines, with Go1 falling below the usability threshold at T3. SUS data for Go1 were not available at all measurement points, limiting trend interpretation.

Table . System Usability Scale (SUS) scores per technology and overall at the 4 measurement time points (T0-T3).

Technology	T0 score, median (IQR)	T1 score, median (IQR)	T2 score, median (IQR)	T3 score, median (IQR)
Double3	68 (22.5)	71 (19.25)	80 (12.5)	75 (—[a])
PICO 4	85 (12)	85 (30)	69 (15)	70 (27.5)
Go1	—	70 (10)	—	64 (34.38)
Overall	74 (15.7)	75 (18.25)	74 (12.5)	72 (27.81)

[a]Not applicable.

Table 5 shows caregivers’ perceived satisfaction with autonomy, competence, and relatedness while interacting with the platform. Data were collected using the TENS-Interface from T1 onward. Autonomy and competence increased across iterations, indicating growing confidence and mastery, while relatedness showed minor fluctuations. Overall, the platform interface effectively supported caregivers’ needs, particularly autonomy and competence.

Table . Technology-based Experience of Need Satisfaction (TENS)–Interface subscale scores at 3 of the 4 measurement time points (T1-T3).

TENS-Interface	T1 score, median (IQR)	T2 score, median (IQR)	T3 score, median (IQR)
Autonomy	18 (3.5)	19 (3.75)	22 (5)
Competence	20 (3.5)	20 (3.5)	23 (3)
Relatedness	16 (5)	18 (1.75)	17 (3.75)

The 1-way ANOVA revealed no significant differences in cumulative SUS nor TUI scores at T3 based on gender, qualification, or facility. Pearson correlations indicated strong associations between SUS and TUI usability (r=0.809), usefulness (r=0.773), and intention to use (r=0.751). Intention to use was highly correlated with perceived usefulness (r=0.926). Higher skepticism correlated with lower usability (r=−0.856) and usefulness (r=−0.736). Greater technology interest correlated with higher curiosity (r=0.861). Higher qualification levels were associated with lower technology fear (r=−0.800), and more professional experience was associated with lower interest in technology (r=−0.766). Competence in handling the interface correlated strongly with autonomy (r=0.912) and positively with technology interest (r=0.716).

Hierarchical regression analyses indicated that perceived usefulness (β=0.908, P<0.001) and fear of technology (β=0.102, P=0.04) were significant predictors of intention to use robotics ($F_{1,6}$=1557.926; P<0.001; R^2=0.998; adjusted R^2=0.997). Multimedia Appendix 1 provides the complete results of the ANOVA, correlation matrices, and regression models.

Qualitative Evaluation

The qualitative evaluation comprised 7 think-aloud protocols and 3 focus group discussions conducted across 4 iterative workshops. The analysis yielded 36 codes, which were condensed into 13 subcategories and grouped into 4 overarching categories reflecting platform requirements: usability and interaction (category 1), intervention design and implementation

XSL•FO
RenderX

(category 2), training and skill development (category 3), and structural prerequisites (category 4). The full coding framework is provided in Multimedia Appendix 2.

Category 1 encompasses user-friendliness and interaction with the platform. Participants emphasized the need for simple and familiar operating concepts, such as gesture- and voice-based input, as well as a streamlined selection process with options for customization. As one caregiver put it, "What's important is that it's simple, easy to use, and works in just a few steps" (T1, Nurse 3). The platform should also enable centralized management of multiple technologies and provide interfaces to existing systems.

Category 2 focuses on intervention design and implementation. It emphasizes technological autonomy, flexible planning and booking systems, and coordination by nursing staff. Personalization emerged as a central requirement, necessitating adaptation of content to the biographies, mobility levels, and cognitive limitations of care recipients. Participants also highlighted the value of user-specific profiles to support personalization and efficiency: "You would need to create a profile so you can tap on the user who is supposed to use it, and everything that was previously stored for that person is already there" (T1, Nurse 3). Interventions were expected to be meaningful and to provide recognizable benefits, thereby supporting individualized care.

The platform was also expected to support training and skill development among care professionals (category 3). This included the provision of structured content, manuals, and step-by-step guides to facilitate independent learning, regardless of prior digital skills. As one participant noted, "If we were to work with it now, we would first need a written, step-by-step guide telling us exactly what we have to do" (T1, Nurse 2). In addition, participants emphasized the need for information on care processes and for safe practice environments in which new technologies could be tested.

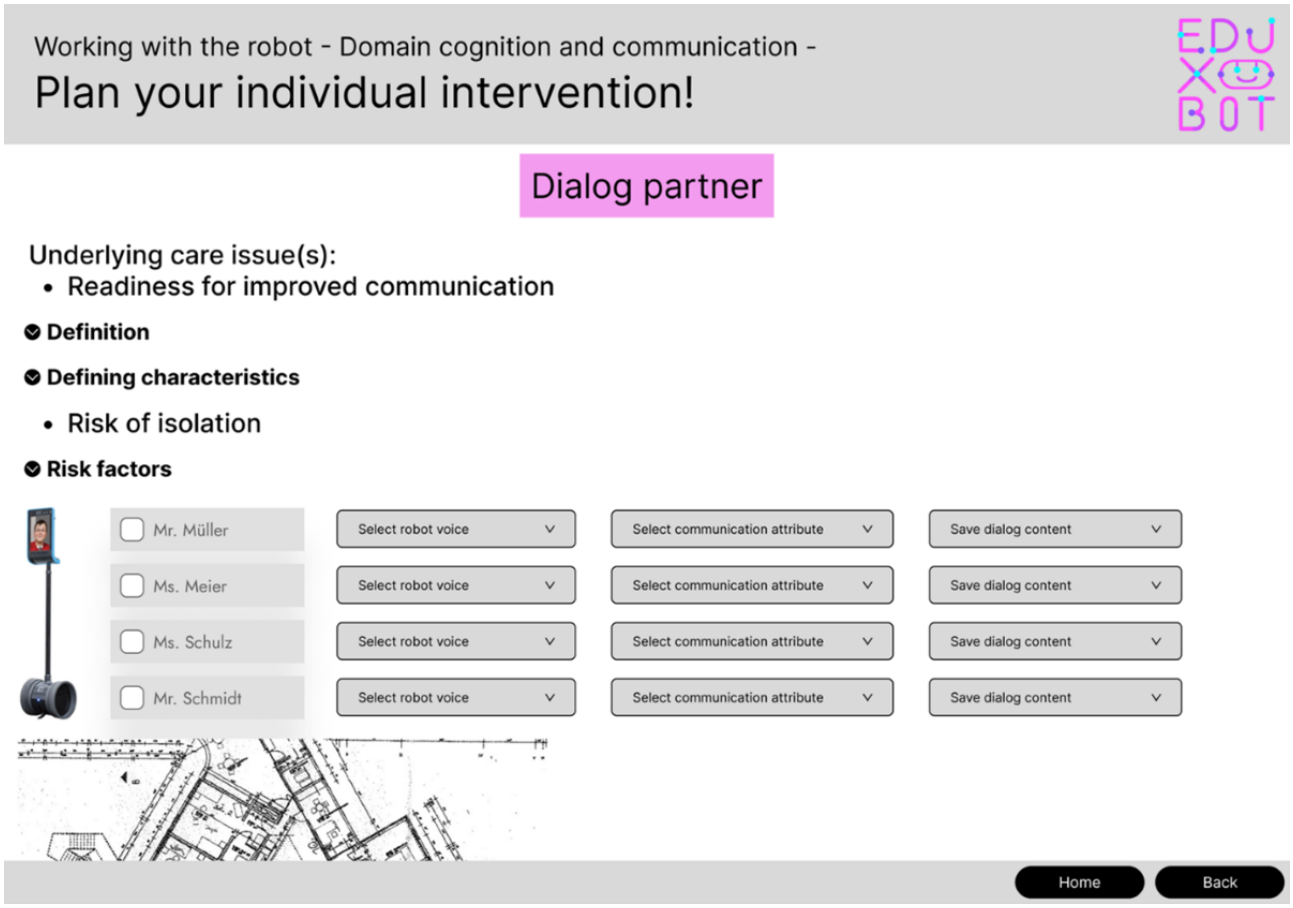
Structural prerequisites (category 4) describe the framework conditions required for successful implementation. These included stable internet infrastructure, access to technical support, and compliance with privacy and data protection regulations. Financial considerations were also emphasized: "Usability and cost have to match. You need something that really makes sense" (T1, Nurse 13). Available resources and the cost-effectiveness of the technology were perceived as decisive factors influencing the platform's long-term adoption.

Initial intercoder agreement was low (16.28%, κ=0.16), likely due to inconsistent segment boundaries. After refining the coding procedures, including the use of sentence-bounded segments and consolidation of enumerations, agreement increased to 82.19% (κ=0.81), indicating reliable coding for analysis.

Iterative Development and Final Operating Concept

The platform was refined through 4 iterative workshops, during which qualitative findings were continuously triangulated with quantitative measures (SUS, TUI, and TENS-Interface). This iterative process enabled the identification and resolution of usability and workflow-related issues across successive development stages.

Iteration 1: Initial Requirements



In the first iteration, participants defined core requirements for the platform. A tablet-based interface using familiar gestures (eg, tap, swipe, pinch-to-zoom) and voice input was preferred, enabling centralized control of multiple technologies. Integration with existing documentation systems was considered essential to avoid additional workload. Participants also favored concise, context-sensitive guidance: "Sure, absolutely. A brief description. So that the employee knows that I can use it for that purpose" (T0, Nurse 1). Quantitative baseline data indicated acceptable usability and a moderate intention to use robotics.

Iteration 2: Conceptual Prototype

The second iteration translated these requirements into a visual prototype. The prototype displayed all workflow steps on a single screen, including process information (care problem definitions, risk factors) presented in expandable drop-down menus, personalization options for technological interventions, and information on technology availability and location. Figure 2 shows the platform prototype.

XSL•FO
RenderX

Figure 2. Prototype representation of the Educational Exploration Robot Application Platform (EduXBot) platform (iteration 2).

Although participants valued the transparency of having all information readily accessible, extensive vertical scrolling was perceived as inefficient and contrary to the goal of minimizing interaction steps: “So it’s important that it’s simple, easy to use, and can be done in just a few steps” (T1, Nurse 3). The introduction of user profiles reflecting mobility, cognitive abilities, and biographical background to support personalization was positively received. Participants consistently emphasized that interventions should provide a discernible benefit and enable caregivers to actively support residents’ experiences: “What’s the goal? What’s the benefit?” (T1, Nurse 7).

At the same time, participants reiterated the need for written instructions (“So if we were to work with it now, we would first have to get it in writing, know step by step what we have to do” [T1, Nurse 2]) and brief training (“You have to practice a little bit, the handling, it takes some getting used to” [T1, Nurse 2]), particularly for more complex technologies.

Quantitative measures indicated stable usability and intention to use. The TENS-Interface showed moderate satisfaction with autonomy, competence, and relatedness. These metrics substantiate the qualitative findings, indicating that usability and acceptance were generally adequate but could benefit from workflow simplification and clearer guidance.

Iteration 3: Functional Prototype

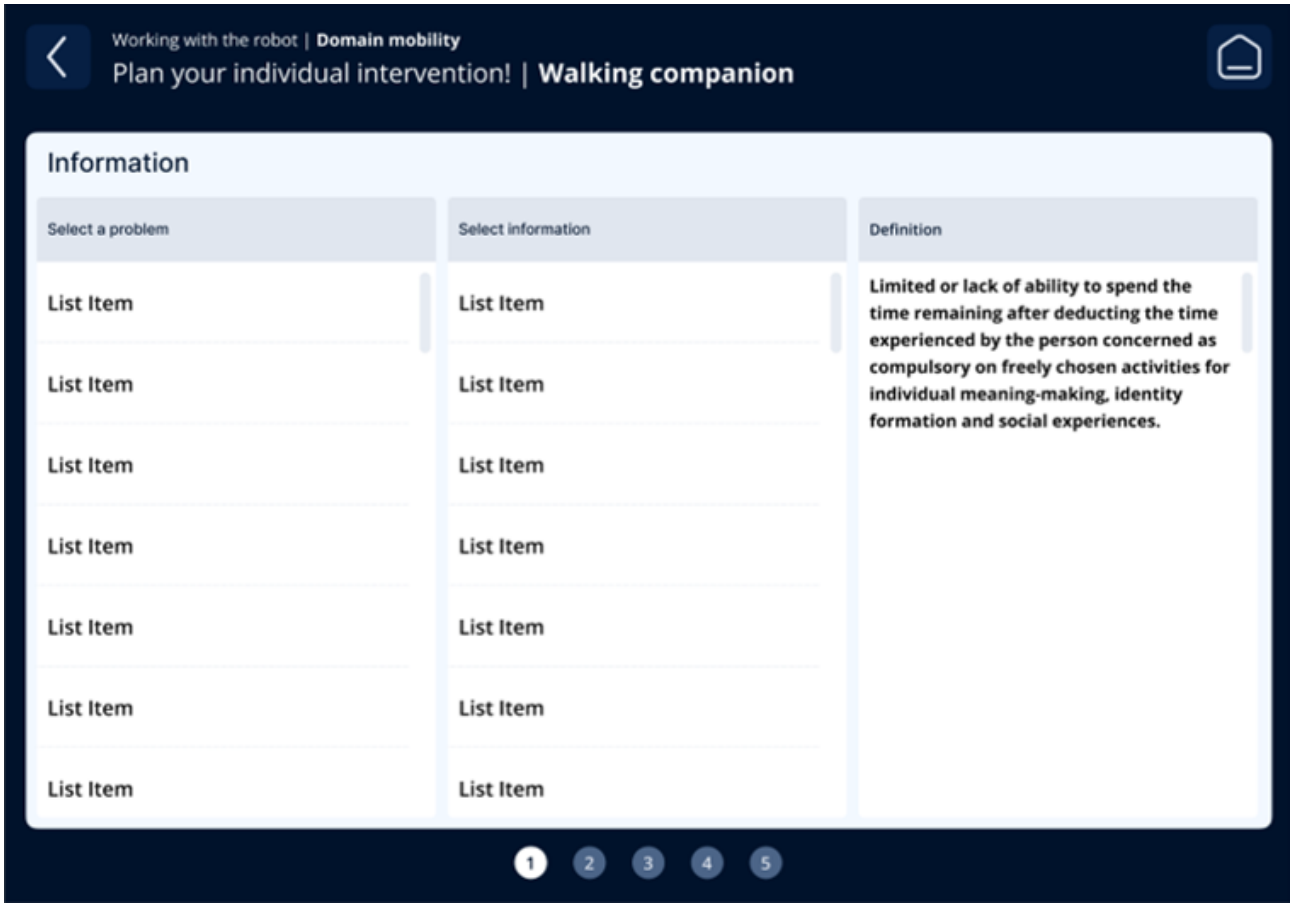
In the third iteration, development shifted toward technical implementation. Full functional integration was available only for the PICO 4, while other technologies were simulated. This partial implementation revealed new usability challenges related to system feedback and transparency.

The management of VR content involved storing videos in a backend system, requiring several preparatory steps prior to use. System states were represented graphically using checkmark symbols: A single gray checkmark indicated assignment to a resident, two gray checkmarks indicated availability on the tablet, and two blue checkmarks indicated availability on the VR headset. Participants perceived this symbolic logic as lacking intuitive clarity: “Dots and hooks in blue, gray, and so on. It’s not intuitive” (T2, Nurse 7).

Additional confusion arose from synchronization issues between the tablet and the VR headset. Synchronization had to be actively initiated via an eye icon within the video control bar. Participants instead tapped the video preview on the tablet, expecting the VR headset to mirror the same content. Although participants relied on a paper-based manual containing step-by-step instructions, several emphasized that intuitive design should ultimately reduce reliance on such materials.

The absence of explicit safety alerts was identified as a critical shortcoming. During simulated testing of the walking partner use case, participants stressed the need for clear error or event notifications, particularly in the case of falls: “It runs in a specific area, detects falls, and alerts nursing staff via the nurse call system” (T2, Nurse 10).

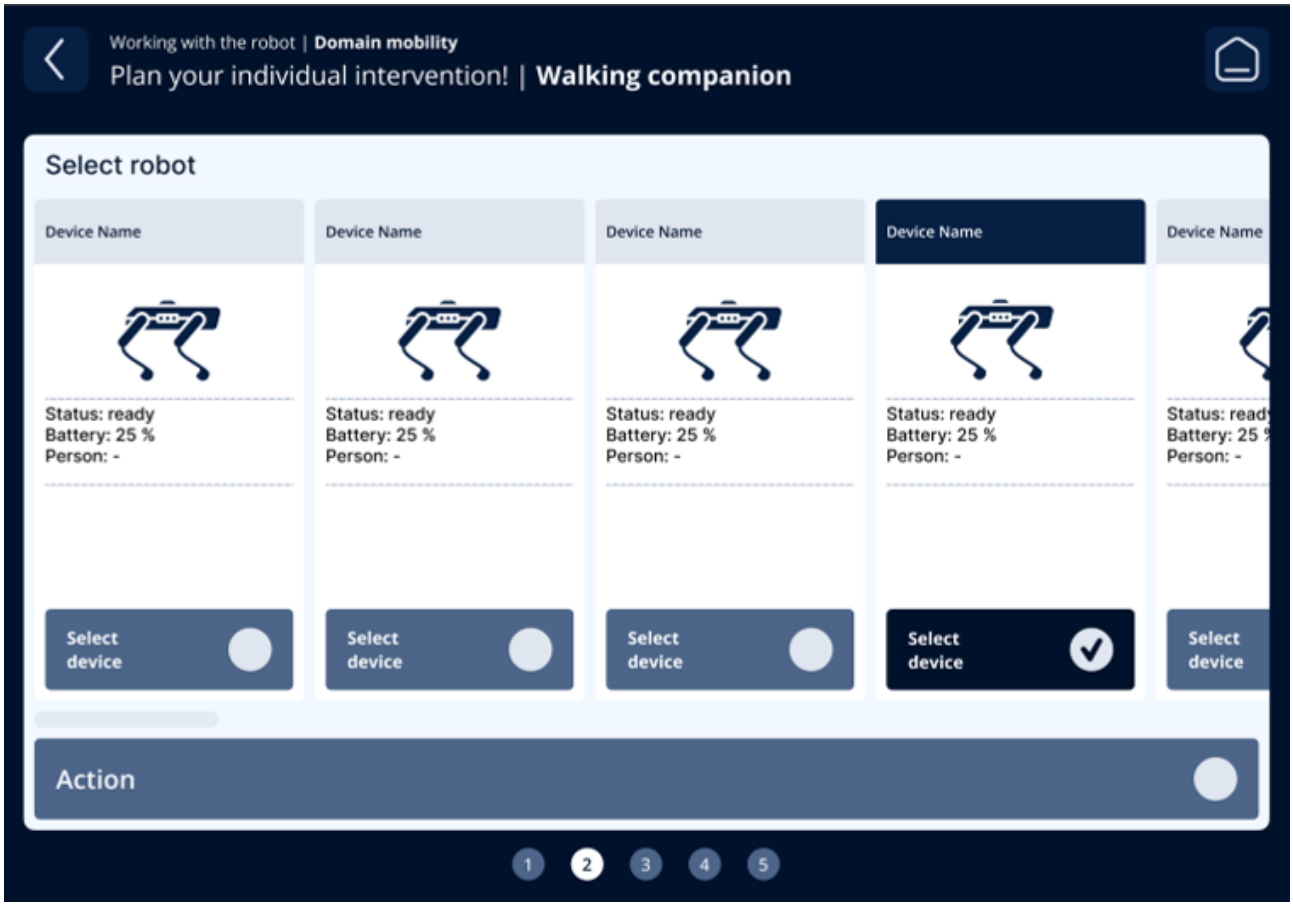
SUS scores for the PICO 4 decreased slightly, indicating usability challenges during partial implementation. In contrast,



XSL•FO
RenderX

TENS-Interface scores showed modest improvements in competence and autonomy. This suggests that participants recognized the platform's potential despite ongoing functional limitations.

Iteration 4: Final Operating Concept



The fourth iteration resulted in a guided, step-by-step workflow aligned with nursing reasoning: (1) contextual information on the care problem clarifying the intended nursing objective of the intervention (Figure 3); (2) selection of the appropriate technology, including system feedback on availability, current usage, and battery status (Figure 4); (3) assignment of the intervention to one or more care recipients (Figure 5); (4) individualization of intervention parameters and scheduling via a booking system (Figure 6); and (5) a final overview summarizing all selected settings with an explicit confirmation step (Figure 7). These figures present the final operating concept.

Figure 3. Contextual information on the care problem.

RenderX

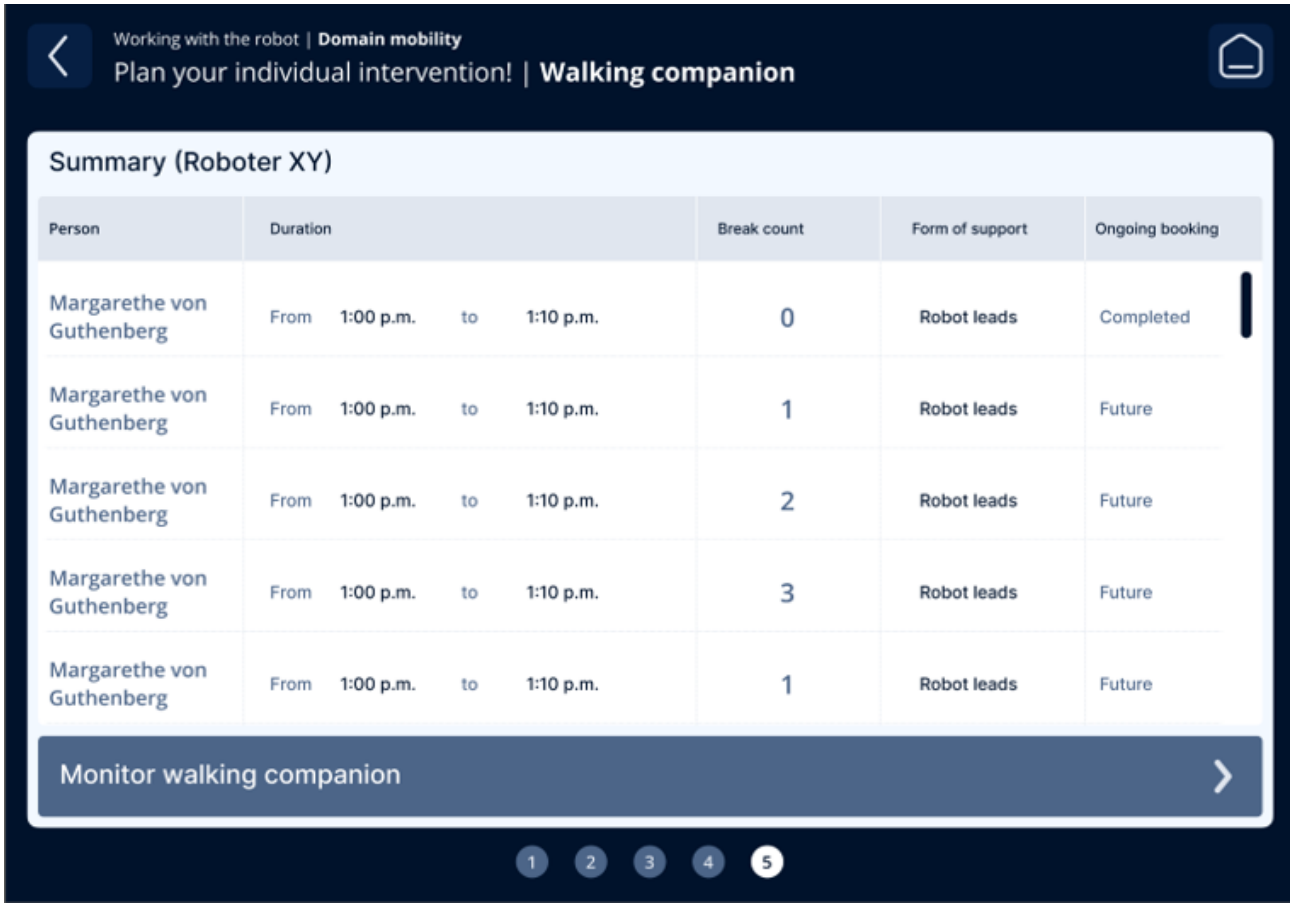
Figure 5. Assignment of the intervention.



XSL•FO
RenderX

Figure 6. Individualization of intervention parameters and scheduling.

XSL•FO
RenderX

Figure 7. Final overview summarizing all selected settings.

The execution and monitoring of interventions were also revised. Care professionals retained the ability to enter an ongoing intervention at any time. Preparatory steps, such as file transfers to the tablet or synchronization with the PICO 4, were executed automatically and presented to users via a unified loading indicator. Safety-related events (eg, falls) were implemented as high-priority alerts using prominent pop-up notifications combined with audible warning signals. In addition, a conceptual interface to existing documentation systems was introduced to support routine care documentation, using standardized text modules to demonstrate the transfer of intervention-related information.

Quantitative data indicated stable or improved usability, a high intention to use, and increased satisfaction with autonomy and competence, suggesting that the revised workflow successfully addressed previously identified barriers.

Discussion

Integrative Overview

This study examined the feasibility, acceptance, and usage requirements of a cross-device interaction platform for controlling robotic systems in nursing care. Quantitative measures (SUS, TUI, TENS-Interface) and qualitative methods (think-aloud sessions and focus groups) were first analyzed separately and subsequently integrated in a mixed methods approach. The primary research question regarding overall platform feasibility was addressed through usability and interaction measures, while secondary questions concerning workflow integration and personalization were examined through combined TENS-Interface and qualitative feedback. The data were integrated both formatively, to inform iterative platform refinement, and summatively, to evaluate the platform's overall feasibility and value. This comprehensive approach allowed convergent and divergent findings to be interpreted in context.

Usability and Interaction

Caregivers demonstrated high levels of curiosity, perceived usefulness, and intention to use robotic technologies, accompanied by low levels of skepticism. Perceived usefulness emerged as the strongest predictor of intention to use robotic systems. These findings indicate that resistance among nursing staff is not the primary barrier to technology adoption. Rather, successful integration depends on whether technological solutions adequately address users' practical needs.

Although SUS scores revealed usability challenges—particularly for the Go1 robot and the PICO 4 headset—these issues largely reflect the constraints of iterative prototype development rather than fundamental rejection by users. These findings align with the qualitative findings. Early usability challenges were primarily related to complex interaction sequences, unclear system feedback, and inconsistent symbolic representations. Participants emphasized the need for intuitive, gesture- and voice-based input, streamlined workflows, and consistent symbolic representations. Iterative refinements, such as simplified step-by-step procedures and automated preparatory steps, directly addressed these usability challenges. Notably,

XSL•FO
RenderX

acceptance and intention to use remained high even when usability temporarily declined.

The triangulated evidence demonstrates that high perceived usability and meaningful interaction design are critical enablers of platform adoption, supporting the primary research question regarding overall platform feasibility. This pattern is consistent with the Technology Acceptance Model, which emphasizes perceived usefulness as a stronger determinant of adoption than ease of use alone [50].

Personalization and Workflow Integration

Participants consistently emphasized the importance of tangible benefits, including automation of routine processes, integration into existing documentation systems, and the ability to tailor interventions to individual care recipients. Technology skepticism was mitigated when systems were intuitive, workflows were transparent, and benefits were clearly recognizable. These findings align with previous research demonstrating that technologies lacking practical relevance or workflow integration are unlikely to be adopted in nursing care [7,8,11]. The strong emphasis on personalization further supports existing evidence that user-centered and cocreative design approaches enhance acceptance, satisfaction, and care-related outcomes [21-24].

Training and Implementation Support

Training and implementation support were identified as critical enablers of successful adoption. Participants' feedback on instructional materials, step-by-step guidance, and protected environments for testing technologies was reflected in increasing TENS-Interface competence scores. Nursing staff reported growing confidence in their ability to use the platform safely and independently. These findings are consistent with Basic Psychological Need Theory, which posits that satisfaction with competence and autonomy fosters motivation and engagement [51]. In line with the Motivation, Engagement, and Thriving in User Experience model, improvements in autonomy and competence were associated with greater willingness to engage with robotic systems [38].

Structural Preconditions and Organizational Perspective

Although quantitative analyses did not directly capture organizational factors, qualitative findings underscored critical preconditions for successful implementation: stable technical infrastructure, access to technical support, compliance with privacy and data protection regulations, and cost-effectiveness. Participants with managerial responsibilities provided insights into resource allocation and long-term sustainability, emphasizing that organizational and structural factors must be addressed alongside usability and personalization to ensure successful adoption.

Limitations and Strengths

A major strength of this study is its iterative, user-centered development process, which systematically involved nursing staff through cocreative workshops and repeated prototype evaluations. The integration of qualitative and quantitative data enhanced the depth, credibility, and interpretability of the findings. Adherence to established methodological standards (GRAMMS, MMAT) and formal ethical approval further strengthen the study's rigor.

Several limitations must be acknowledged. The small and relatively homogeneous sample of 13 participants—many of whom held managerial roles and reported positive attitudes toward technology—limits generalizability and may reflect selection bias. Continuous involvement across multiple iterations may have influenced participants' evaluations, as familiarity with successive prototypes could lead to more favorable perceptions of improvement. Social interaction with the research team may also have increased the likelihood of socially desirable responses.

The absence of a control group restricts the ability to obtain independent, neutral assessments of usability and perceived benefit. In addition, participation was limited to two facilities with prior experience in research projects, potentially underrepresenting settings or individuals who are more skeptical of or burdened by technology. Finally, evaluations were conducted in simulated environments rather than routine clinical practice, limiting conclusions about long-term usability, scalability, and impact on care outcomes. The study also focused on a limited set of technologies and did not include perspectives of care recipients. Accordingly, the findings should be interpreted as exploratory rather than confirmatory.

Implications for Practice and Future Research

This study demonstrates that a unified, cross-device platform for robotic systems can be successfully developed through sustained end user involvement. Although the platform was initially designed to operate robotic technologies, needs articulated during the early requirements assessment led to the integration of VR content via the PICO 4 headset. This development illustrates the platform's extensibility beyond robotics to other digital assistive technologies. Such flexibility is essential for future-oriented nursing environments, as it enables the centralized control of multiple technologies through a single interface while preserving usability and opportunities for personalization.

Nursing staff expressed willingness and motivation to use robotic technologies; however, successful implementation depends on intuitive usability, meaningful personalization, seamless workflow integration, and structured training. Quantitative improvements in autonomy and competence were reflected in design features that support familiar interaction patterns, centralized control of multiple technologies, and adaptation to individual care needs. Qualitative findings further emphasized the importance of personalization, transparent workflows, and integration with existing documentation systems for both acceptance and actual use. Collectively, these results suggest that technological rather than human factors represent the primary barriers to the integration of robotics into nursing care. Such barriers can be mitigated through collaborative design, iterative refinement, and close alignment with everyday care practices.

Future research should complement participatory development approaches with evaluations conducted by independent user

XSL•FO
RenderX

groups who were not involved in the design process. This would allow assessment from a more neutral perspective and reduce potential biases associated with repeated exposure or social desirability. Expanding participant diversity, including staff with lower digital affinity, will further strengthen generalizability. Testing the platform in real-world care settings with larger and more heterogeneous samples and incorporating the perspectives of care recipients will be essential to evaluate long-term acceptance, effectiveness, and impact. Given its open architecture, the platform provides a promising foundation for integrating additional assistive technologies and supporting broader digital transformation in nursing care.

Acknowledgments

The authors declare the use of generative artificial intelligence (GAI) in the manuscript preparation process. In accordance with the GAIDeT taxonomy [52], the following task was delegated to a GAI tool under full human supervision: translation. The GAI tool used was DeepL. Full responsibility for the content of the manuscript rests with the authors. GAI tools are not listed as authors and do not bear responsibility for the final manuscript or its conclusions.

Funding

This research was funded by the Federal Ministry of Research, Technology and Space as part of the WIR!—Wandel durch Innovation in der Region funding scheme (grant ID: 03WIR3118B). The project was funded for a 3-year period starting in January 2023, with a total funding volume of €129,805 (US $149,709). The funding body had no role in the study design, data collection, analysis, interpretation of data, or the writing of the manuscript.The authors acknowledge the financial support of the Open Access Publication Fund of Martin Luther University Halle-Wittenberg.

Abstract

Background: Patients undergoing cancer treatment experience a significant symptom burden. The standard process of symptom management includes patient reporting and clinical response following symptom escalation. Emerging predictive symptom models use artificial intelligence (AI) components of machine learning and deep learning to identify the risk of symptom deterioration, facilitating earlier intervention to prevent downstream effects. However, integrating predictive symptom models into clinical practice will require oncology nurses to adopt innovative approaches.

Objective: This study aims to explore oncology nurses' perceptions of the use of predictive symptom models in cancer care and the factors influencing the adoption of this symptom care innovation.

Methods: The evaluation was guided by the Rogers Diffusion of Innovation Theory, which describes the process of how individuals adopt new technologies. The investigators developed an interview guide that asked oncology nurses to rate their perceptions of AI symptom models on a Likert scale. Participants were also asked to provide qualitative comments to support their ratings for each question, in order to better understand the key factors that would influence AI predictive model adoption. Investigators analyzed demographic data and Likert ratings with descriptive statistics. Qualitative analysis of participant comments included content analysis and inductive coding to identify themes. Nurses' perception of factors that would influence the adoption of AI symptom models, based on the Rogers theory, included relative advantage, compatibility, complexity, trialability, and observability.

Results: Responses of 15 oncology nurses with more than 1 year of experience in oncology were analyzed. There was high agreement among nurse participants that an AI model could improve symptom management for patients with cancer (n=10, 67%) and increase early intervention to prevent the escalation of symptoms (n=12, 86%). All participants (N=15) agreed that receiving symptom information would be helpful. Nearly three-quarters of participants (n=11, 73%) endorsed that the information would save time. Most (n=12, 80%) recommended that clinicians receive information about the predicted symptom deterioration of their patients. Among open-ended responses, key themes were consistent with factors identified in the Diffusion of Innovation theory including: (1) perceptions related to the AI model (compatibility or complexity), (2) nurses' perception of patients' benefit (observability), (3) improved clinical processes (relative advantage or observability), (4) apprehension over model accuracy and impact (compatibility or trialability or observability), and (5) implementation or adoption (trialability or complexity or observability).

Conclusions: Oncology nurses agree that predictive symptom models could help improve symptom management for patients undergoing cancer treatment. However, nurses noted that transparency in the factors included in the AI model was essential, that nurses should be involved in the development and testing of models, and that the observability of the benefit in symptom care would need to be evident for ultimate adoption.

Introduction

Patients undergoing cancer treatment experience a wide range of symptoms that impact functional status, quality of life, and health care use [1-3]. Currently, symptom reporting is a reactive process based on patient reporting, followed by a response for poorly controlled symptoms. Oncology nurses have historically screened patients both at clinical visits and via phone triage when patients report increasing symptom burden [3]. Increasingly, but slowly, clinical workflows are implementing symptom monitoring with electronic patient-reported outcome (ePRO) systems, which enable patients to report symptoms electronically and allow oncology clinicians to respond accordingly [4]. However, the ePRO-based symptom management decreases care escalations, which is notable given that worsening of symptoms is a primary driver of health care use among patients with cancer [3]. However, oncology symptoms can change rapidly, and some, such as fever, require prompt evaluation and clinical action [5,6]. While responsive ePRO reporting systems have improved patient symptom burden, high levels of symptoms and health care use persist. ePRO symptom models remain reactive, with detection following a patient reporting a change and lacking the ability to anticipate symptom escalations.

One application of artificial intelligence (AI) is the use of computer-based models to analyze large quantities of data, in this case, symptom data. Predictive symptom models attempt to evaluate data and detect a change prior to patient symptom escalation. AI models are being tested using retrospective and prospective data [7]. AI models, paired with ePRO collection, are being developed to enable predictive and anticipatory warnings that may help categorize patients at an increased risk of symptom escalation [8]. AI models use patient-generated data to predict the likelihood of a specific outcome or a set of outcomes [8]. Models to diagnose both diseases and symptoms, as well as health care use, are being integrated into oncology use cases [7,9]. Predictive symptom models, which inform the identification of symptom patterns, show promise as a mechanism to enhance the accuracy of symptom detection before escalation [7,10]. AI-derived alerting models, using machine learning (ML) or deep learning methods, have the potential to predict emerging symptom escalations. These models seek to prioritize patients at increased risk for changes before symptom escalation. Detecting symptoms, such as an impending fever, before the patient experiences it can facilitate earlier intervention and better outcomes [11]. Alternative predictive approaches are necessary to detect dynamic symptom changes while reducing the burden of symptom reporting.

Transitioning to proactive care models requires a complete shift, both cognitively and operationally, for both patients and clinicians. Moving from a reactive reporting structure to a predictive symptom management model requires adoption by the oncology team. Notably, the implementation of this shift will require the engagement of oncology nurses, who will be the clinicians responsible for responding to AI-based alerts.

Few studies have examined nurses' perceptions of implementing AI-based symptom models [12]. A recent study that assessed nurse perspectives on ML-based clinical decision support systems broadly found that previous experience with technology and nurse perceived engagement in the development process, among other factors, influenced perceived use of ML clinical decision support systems [13]. The use of AI in the clinical setting is expanding, and a key theme consistently identified by nurses, nurse informaticists, and nurse leaders regarding the development, implementation, and adoption of AI-based tools is the importance of engaging nurse end-users at the beginning of the development process [14-16]. Thus, the purpose of this evaluation was to examine nurses' willingness to adopt AI-derived alert notifications about impending symptom escalations. In anticipation of implementing these AI-based symptom management systems, this exploration addresses an existing gap in the literature regarding oncology nurses' perceptions, including usefulness and anticipated efficiency, of AI-derived symptom prediction models for cancer symptom management.

The Rogers Diffusion of Innovation Theory describes the process of how users decide to participate in the adoption of new technologies [17] and framed our work to nurses' consideration to adopt AI. Using AI-based models in clinical practice will require a significant transition from current symptom evaluation processes, and oncology nurses, who are largely responsible for symptom triage, will need to adopt and use this innovation in care management workflows. Perception of the innovation, rather than the innovation itself, is key to adoption. The Diffusion of Innovation theory identifies 5 perceived attributes that influence adoption, including relative advantage, for this study whether the AI predictive models are perceived as improving current symptom monitoring and would benefit patients; compatibility—whether the AI predictive models are consistent with symptom treatment values, past experiences, and the needs of nurses providing symptom care; complexity—whether AI predictive models are seen as easy to understand and use; trialability—whether the AI predictive models can be piloted and tried out; and observability—whether the symptom management benefits of the AI predictive models can be seen by the nurses. According to the theory, adoption occurs at varying speeds based on individual characteristics and perceptions, such that a small percentage of the population will be innovators and early adopters, and others are more likely to adopt later after others have accepted the innovation. The focus of this study is on these factors and how they may influence nurses' perceptions and decision-making about the adoption of AI predictive symptom models.

Methods

Design, Setting, and Participants

We conducted a mixed methods exploration of oncology nurses' perspectives regarding the use of AI-based symptom predictive models to detect symptom changes in patients with cancer. The use of both structured questionnaire (eg, Likert-scale questions) and interview questions allowed for a more in-depth analysis of perspectives regarding the adoption of AI predictive symptom models and is well-suited for implementation research [18] Specifically, we conducted interviews with participants using

XSL•FO
RenderX

both structured, Likert-scale–based questions and open-ended questions.

A convenience sample of registered nurses with at least 1 year of experience in oncology from across the United States was recruited to participate in this project. Participants were excluded if they lacked fluency in spoken or written English, lacked access to Zoom (Zoom Communications, Inc) web-conferencing technology or were unable to meet in person, or if they had less than 1 year of experience as a nurse in oncology. Recruitment methods included direct professional referrals, social media (such as LinkedIn and Facebook), and snowball sampling. Investigators contacted participants via email to schedule interviews. Interviews, the duration of which ranged from 20 to 30 minutes, were conducted in December 2024 and January 2025 via web teleconferencing platform (Zoom) and in-person by 2 investigators (BN and EAS). Interviews were not recorded or transcribed, though detailed notes were kept by the investigators who conducted the interviews and included capturing verbatim quotes from participants.

Individual Interviews

The team developed the interview guide (Multimedia Appendix 1) to gather information on the acceptability of implementing AI predictive symptom monitoring and management. The interview guide was initially drafted by 2 investigators (BN and EAS) and feedback was obtained from other members of the team before being finalized (Multimedia Appendix 1). Before starting the interview, as outlined in the interview guide, the concept of an AI-based symptom model was presented to the participants. The description was broad in that it included general model types but emphasized the predictive capability of AI algorithms in the identification of symptom deterioration. In addition to demographic questions, the final interview guide consisted of 6 total Likert-scale questions, in which participants responded to statements about the hypothetical clinical usefulness and efficiency of a symptom prediction model, indicating their agreement or disagreement using the Likert scale (1="Strongly Disagree" to 5="Strongly Agree"). Following each Likert-scale question, participants were asked to provide open-ended comments in response to the Likert-scale question that they had previously answered. Three additional open-ended questions were meant to elicit additional information, for example, "If you received a notification that your patient is at high risk for experiencing worsening symptoms in the next 24 hours, what would you do?"

Saturation was assessed on an ongoing basis. No new information was elicited, and subsequently, no new codes were identified over the final 5 interviews, indicating that we achieved content-level saturation.

Data Analysis

Quantitative Analysis

Descriptive analyses, including means and SDs, were calculated using demographic data to describe the sample. Due to the small sample size, we rounded frequencies (percentages) to the whole number. Additionally, investigators evaluated the frequency of Likert ratings by participants through descriptive statistics. The Likert-scale ratings were on a 1 to 5 rating with responses initially coded based on a 1 to 5 rating (1="Strongly disagree," 2="Disagree," 3="Neutral," 4="Agree," and 5="Strongly agree"). However, in further analyses, we combined ratings of 1 to 2 and 3 to 5 to create categorical ratings of "Disagree," "Neutral," and "Agree." Methodologically, this approach is used to improve interpretability in smaller sample sizes, which have limited responses in multiple categories [19]. Our quantitative analysis of Likert-scale responses ultimately provided a clearer picture of the reportable trends within the sample.

Qualitative Analysis

For qualitative analysis, the team members (BN and EAS) used open coding and initially coded qualitative responses independently. After resolving disagreements and reaching consensus on codes, the investigators recoded each qualitative interview. Data were then analyzed using thematic analysis which involved several steps: data familiarization, keyword selection, identification of initial themes, and comparison of the investigators' initial themes.

Triangulation

In keeping with a mixed methods approach, the investigators synthesized quantitative and qualitative data and identified findings that converged, complemented, or diverged across data modalities [20,21]. Quantitative data from Likert-scale responses were triangulated concurrently with qualitative, open-ended responses to the questions and/or follow-up prompts. Finally, the investigators compared the codes for the factors within the Diffusion of Innovation Model. Participant quotes were used to represent themes. We used the GRAMMS (Good Reporting of a Mixed Methods Study) guidelines to aid clarity of reporting (Checklist 1) [22].

Ethical Considerations

The University of Utah Institutional Review Board reviewed the project protocol and deemed it a quality improvement project and not human participants research (00166873). Each participant was informed of the purpose of the project, including that participation was and could be discontinued at any time for any reason. Verbal consent was obtained prior to proceeding with the interview. No compensation was provided to the participants. In accordance with the rigor of human participants research, the study team followed procedures to protect the participants' privacy and confidentiality, including deidentifying participant data, not sharing data outside of the study team, and storing data securely on password-encrypted computers.

Results

User Statistics

Sample characteristics are summarized in Table 1. The sample included 15 nurses who self-identified as working in oncology for more than 1 year. Participants were all female (15/15, 100%) with a mean age of 44.6 (SD 11.44) years. The cohort consisted of an experienced group of nurses, with an average of 18.33 (SD 9.82) years of nursing experience. Most of this experience (mean 14.10, SD 9.92 y) was in oncology. Participants reported working in diverse oncology settings, including inpatient

XSL•FO
RenderX

oncology and outpatient infusion, as well as in roles related to quality improvement and patient navigation (Table 1). Furthermore, the sample was highly educated, with 8 out of 15 (53%) having completed a master's degree (Table 1).

Table . Participant demographics (N=15).

Characteristics	Participants
Age (y), mean (SD)	44.6 (11.44)
Years of experience, mean (SD)	18.33 (9.82)
Years of experience in oncology	14.10 (9.92)
Highest level of education, n (%)	
Diploma	1 (7)
Bachelor's degree	4 (27)
Master's degree	8 (53)
Doctoral	2 (13)
Practice environment, n (%)	
Inpatient oncology	4 (26)
Outpatient oncology	8 (53)
Quality	1 (7)
Navigation	2 (13)

Quantitative Evaluation

Results are presented in categorical (agree or disagree) percentages for the 6 Likert-scale questions (Table 2). All nurse participants overwhelmingly agreed that receiving the symptom information would be helpful, signaling compatibility with existing values. Furthermore, 12 out of 15 (86%) nurses believed that an AI model would enable early intervention to prevent the escalation of symptoms, aligning with this view. Most nurses (12/15, 86%) also thought that an AI model would allow the relative advantage of early intervention to prevent the escalation of symptoms. A smaller majority, or 10 out of 15 (67%) nurses, agreed that an AI model could improve symptom management for patients with cancer. The remaining one-third or 5 out of 15 (33%) participants were neutral about whether the symptom prediction model could help improve symptom management related to the disease. There was similar agreement on the expectation that a symptom prediction model would enhance a patient's quality of life, with 10 out of 15 (67%) nurses agreeing. From an efficiency perspective, 11 out of 15 (73%) nurses felt that the information may save time. Despite nurses obtaining significant volumes of clinical information during a clinical day, 12 out of 15 (80%) nurses recommended that clinicians receive information about the predicted deterioration of their patients.

XSL•FO
RenderX

Table . Perceptions of artificial intelligence (AI) predictive ratings' value in oncology symptom management (N=15).

Topic	Disagree, n (%)	Neutral, n (%)	Agree, n (%)
Knowing that a patient is at risk of symptom deterioration earlier is helpful information for me to have as an oncology clinician	0 (0)	0 (0)	15 (100)
I expect that information from an AI model would allow me to intervene earlier, preventing an escalation of patient symptoms.	0 (0)	2 (13)	12 (86)
I would recommend oncology clinicians receive information about predicted deterioration from an AI algorithm when caring for patients with cancer.	1 (7)	2 (13)	12 (80)
Having this information might save me time and/or help improve my efficiency in helping my patients reduce their symptom burden	1 (7)	3 (20)	11 (73)
I expect information from an AI model would add to reducing symptom burden and improve my patients' quality of life.	2 (13)	3 (20)	10 (67)
I expect information from an AI model would help me better manage symptoms related to cancer treatment or disease.	0 (0)	5 (33)	10 (67)

Only 1 out of 15 (7%) respondents indicated that they believed AI-based symptom models would not improve efficiency or would not recommend that oncology clinicians receive information regarding patient deterioration from an AI symptom model. A small number, 2 out of 15 (13%) nurses indicated that AI-based symptom models would not reduce symptom burden or improve quality of life. These concerns reflect fears of complexity, given the complete shift in operational paradigm. A higher percentage of respondents, ranging from 13% to 33%, were neutral in their responses, indicating that they were still considering the information on the innovation.

Qualitative Evaluation

Themes

Participants' comments further explained their perceptions about the development of symptom prediction models, including: (1) factors related to the AI model (compatibility or complexity), (2) nurse perception of patient benefit (relative advantage or observability), (3) improved clinical processes (relative advantage), (4) apprehension over model accuracy and impact (compatibility or trialability), and (5) implementation or adoption (trialability or complexity). Table 3 displays the identified themes, perceptions influencing adoption, and select quotes. Figure 1 highlights the development of themes from codes and the attributes of the Diffusion of Innovation Theory.

XSL•FO
RenderX

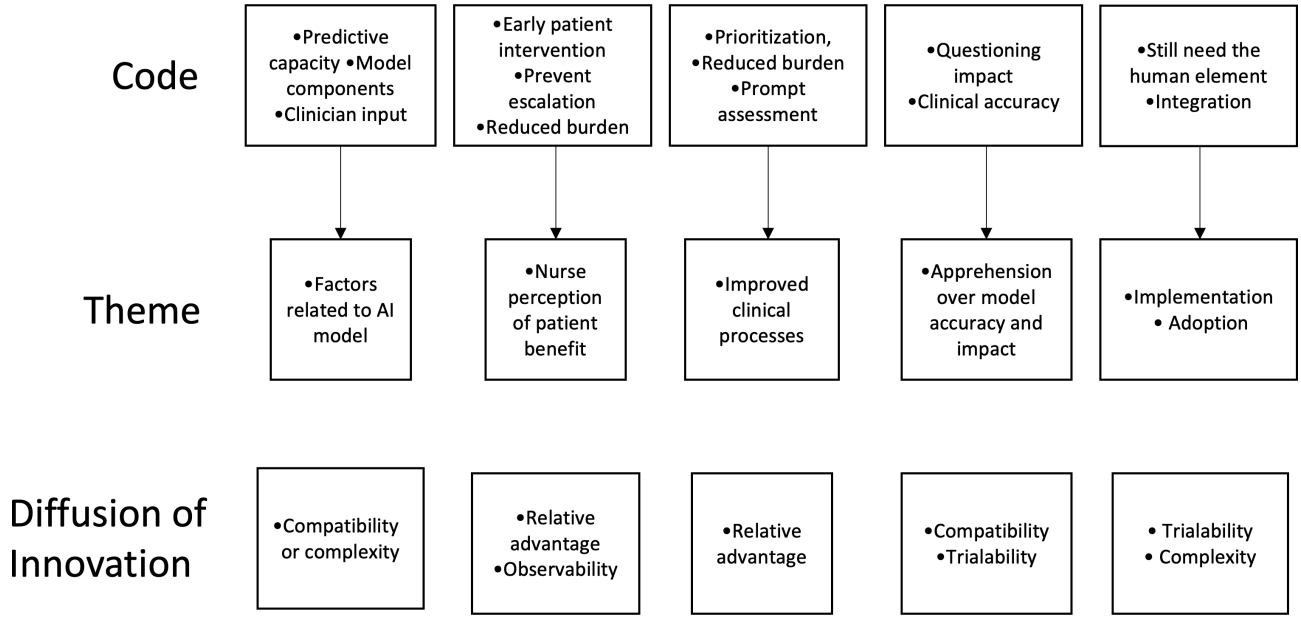

Table . Themes, codes, participant number, and quotes.

Themes	Perception attributes	Codes	Exemplar quote(s)
Factors related to the AI[a] model	• Compatibility • Complexity	• Predictive capacity • Model components • Clinician input	*I think it might help if the algorithm says the patient is likely to develop a fever. What would I do with that information if there were no infectious symptoms? It might be helpful if managing a lot of patients helps someone to rise to the top for check-ins.* [Participant 11] *Depends on where they get their data from. We already know when chemotherapy induced nausea will occur... so if AI is using appropriate standardized resources, I would be fine with that.* [Participant 8]
Nurse perception of patient benefit	• Relative advantage	• Early patient intervention • Prevent escalation • Reduced burden	*...a lot of time patients wait until symptoms are worse to call. We can intervene sooner.* [Participant 14] *Oncology patients can deteriorate quickly, this could help get symptoms before out of control to avoid ER/ hospital visit.* [Participant 1] *If a [model] did exist I would highly recommend [it] to prevent or mitigate life events to help prevent life or death.* [Participant 6]
Improved clinical processes	• Relative advantage	• Prioritization • Reduced burden • Prompt assessment	*Prioritization should occur digitally, rather than me doing it, adding more to my work burden.* [*Participant 12*] *Delays in care, due [to patient] burden of calling in. The RN reaching out directly could increase patient satisfaction and response.* [Participant 12]
Apprehension over model accuracy and impact	• Compatibility • Trialability • Observability	• Questioning impact • Clinical accuracy	*Based on clinical practice, you can usually pinpoint those patients anyway.* [Participant 12] *I don't really know if I would fully trust every time until it proves itself.* [Participant 3]
Implementation or adoption	• Complexity • Trialability • Observability	• Still need the human element • Integration • Workflow • Communication of model output (eg, notifications, text) • Ease of use • Alert fatigue	*AI can't supersede one-on-one contact.* [Participant 10] *[I] would want notifications if they are interruptions… I would want [them] to be relevant.* [Participant 12]

[a]AI: artificial intelligence.

Figure 1. Codes, themes, and diffusion of innovation category. AI: artificial intelligence.

Factors in the AI Model

Themes focused heavily on nurses' ability to understand the factors within the model and test it to assess its predictive capacity, components, and provide input into its development. Predictive capacity refers to the model's ability to make accurate assessments of future behavior. For example, participants emphasized the importance of the model being accurate and relevant to the patient's clinical presentation, reflecting the need for compatibility with existing systems. For example, one participant stated:

> *[I would want to know] … what led to notification, reason behind alert… what was their trend before… algorithm that shows patients who exhibit X also show Y, in the context of what's going on with the specific patient.* [Participant 15]

Participants also commented on specific factors necessary as model components, such as temperature and respiration. Nurses strongly emphasized the importance of involving oncology clinicians in the development of the AI model, highlighting their need to understand its compatibility with current systems.

Patient Benefit

Another theme identified was the benefits to patients, which included codes for early patient intervention, prevention of escalation, and reduced patient burden, all of which are compatible with current systems. Early patient intervention, as noted by many participants, was identified as a benefit of AI-based symptom management and is defined as having contact with the patient in a manner that occurs earlier than standard care as a relative advantage. For example, participants noted that a model could allow them "to intervene earlier before symptoms progress into dangerous situations" (Participant 2) or "prevent hospitalization and improve quality of life by managing symptoms at home" (Participant 8). Early intervention is the mechanism by which ePRO alerting systems have effectively decreased escalations of care from a current setting to a higher level of care, such as an emergency room. Other participants disagreed that patients would benefit more than they already do, with one participant stating:

> *I don't think the AI model will provide much additional information...Nurses already watch for specific symptoms.* [Participant 13]

Nurse participants also focused heavily on reducing the burden of cancer care delivery on patients. They highlighted the fact that the combination of early intervention, for example, early symptom detection, can prevent later-stage symptoms and care escalations, thereby improving the experience of cancer care, which aligns with the goals of current systems, but may also represent perceived advantages over the current system.

Enhanced Clinical Processes

Participants could envision that an AI-based symptom model may enhance the process of clinical care by improving prioritization and response times, thereby facilitating the prompt assessment of clinically significant changes in a manner superior to current systems. Additionally, participants felt that the process of care could decrease clinical burden, for example, stating "being able to streamline information would be helpful" (Participant 7). Nurses also reported wanting to reduce the patient's need for reporting and the burden of care escalations to clinicians. However, some participants also expressed concerns that the model could increase clinical burden and highlighted concerns about complexity, noting:

> *The nurse will have to contact the patient. Just because they have an alert doesn't mean they will have the symptoms.* [Participant 10]

Model Accuracy

Participants also reported it would be imperative to test the model to verify its accuracy, noting that nurses would be more likely to use a model they could participate in testing. Participants cautioned that patient engagement may influence the clinical accuracy of the tool. Many nurses have progressed beyond the initial knowledge stage and are now considering not

XSL•FO
RenderX

only whether, but also how, systems should adopt AI symptom models. Nurses have experience in integrating new technologies into clinical practice; as such, they understand the importance of accepting innovation to facilitate its diffusion and optimal use. Nurse participants also reported some apprehension about the use of AI models. Specifically, participants voiced concerns about the effectiveness and clinical use. Participants noted that training the model with the correct inputs would be crucial in confirming the model's accuracy.

Implementation Processes

Nurses' comments emphasized that decision-making also depends on the practical implementation of AI-based models. Evaluation and trialability of escalation alerts would be necessary for both initial and long-term adoption. Participants reported that AI-based predictive alerts for symptom management will not replace human nurse assessment and response. Participants also noted that the integration into the workflow needs to be seamless. There were many comments related to the importance of ensuring that communication of model output to nurses and other clinical staff does not increase the time burden, though many thought it would. For example, one participant noted, "I don't know it will save time, [it] may add time, but that is the sacrifice to catch something early" (Participant 12). Furthermore, most participants expressed a firm belief that a model could be easy to use and would not contribute to alert fatigue.

Discussion

Principal Findings

The majority of our sample of nurses agree with statements that support the use of AI-based symptom models, reflecting nurses' belief that these models may represent a relative advantage to current practice. The themes that nurse participants identified as essential to the adoption of AI symptom models aligned with the Diffusion of Innovation Theory. Nurses have recognized that the compatibility of AI-based symptom models holds promise for predicting, detecting, and enabling a response to changes in patient symptoms. Nurses' strong agreement to receive symptom information via new models revealed an overall favorable view of this type of model and alignment with existing values. These models align with nurses' strong commitment to providing patients with the best possible care, and by fostering the potential for AI-based symptom management models to improve patient care. Specific benefits identified by participants include improving clinician response by increasing the information clinicians receive and reducing patient burden through the elimination of unnecessary reporting or care escalations. This type of agreement indicates that nurses have progressed beyond the knowledge stage in the innovation process, toward identifying the necessary information to adopt the use of models. Overall, oncology nurses have positive views regarding the perceived advantages for patients and the compatibility with current care. This study demonstrates that many nurses have positive perceptions of the advantages and usability of AI-based symptom models and are now considering the implementation and use beyond the potential value.

Despite support for adoption, nurses urged caution in the development and implementation of these models. In particular, nurses emphasized the importance of involving end-users in the development, pilot testing, and implementation of these models, as this will help determine their value and appropriate integration into clinical workflow, thereby facilitating their adoption. Nurses have experience in integrating new technologies into clinical practice; as such, they understand the importance of accepting innovation to facilitate its diffusion and optimal use. This aligns with a framework developed for designing and implementing AI models from a systematic review, which recommends the inclusion of health care providers in development and implementation [8].

Nurse participants recognized the importance of trialability through accurately training and testing models, as well as ensuring that the data sources used are adequate to positively impact patient outcomes. Nurses strongly felt that model development requires the careful selection of clinically appropriate inputs, such as the inclusion of temperature and laboratory values, to support clinically accurate results. Confirming models that are appropriate for the input data and the desired outcomes is necessary for accuracy. As frontline users, nurses who currently assess patient symptoms should be included in model factor selection and testing. Often, these models are developed in collaboration with other clinical providers, and yet nurses will be the ones to receive the alerts and need to triage them. Trialability and observability for nurses, not just physicians, are keys to adoption. These themes are consistent with the recommendations for transparency in the development of AI-based clinical models, ensuring that both clinicians and patients understand and agree on the inputs to the model [23]. Creating transparent and explainable models is a step toward combating the perpetuation of healthcare bias in AI models and will facilitate long-term adoption [24,25].

While participants identified the need to understand model inputs and testing, they also reported a need to see the model's impact on outcome to feel confident in making clinical decisions based on the model, again underscoring the importance of observability. Model outcome achievement depends on the implementation of models as designed. For this to occur, there must be transparency and trialability of both inputs and clinical outcomes. For example, our early work developing a predictive model demonstrated the ability to predict symptom escalation more accurately in short intervals than at longer intervals [10]. Transparency will enable clinical teams to implement models for the purpose they were developed, thereby supporting accuracy. Efforts to transform and train models for additional uses will need to follow proper rigor to ensure the models are adapted and updated effectively. Transparency and inclusion in development will enable oncology nurses to effectively use AI-based models.

Experienced oncology nurses in our sample reported both a strong interest in using and some reluctance to immediately trust AI-based symptom models. While involving nurses in the development and implementation will facilitate trust, oncology nurses may lack the education and training to understand how these models work. An extensive national survey of nurses revealed that only 30% of nurses are aware of how AI is used

XSL•FO
RenderX

in nursing practice [26]. Although information regarding the use and daily applications has increased in the last several years, this highlights the need to provide AI education to both students and to disseminate it to nurses at the point of care delivery. Future work should specifically evaluate the education needs of oncology nurses regarding AI-based symptom models.

With many clinical symptom escalation models still in development, gaining a clear understanding of nurse perceptions regarding the use, decision to adopt, and maintenance of these models is essential. Our examination revealed that oncology nurses share similar concerns to those documented in the literature regarding the use of clinical predictive models, including alert fatigue and increased time burden, which represent a source of complexity [27]. Additional barriers to adoption of AI technology in healthcare include ethics, technological considerations such as data access and infrastructure, and liability and regulatory issues [28]. However, as evidenced in our results, nurses also hold favorable perceptions that these models have advantages and align with current treatment values, prioritizing the reduction of cancer symptom burden. Implementation strategies that could be used to overcome adoption barriers include, but are not limited to, identifying implementation champions as well as ensuring adequate interpretability of the model [29,30]. AI-based symptom models have the potential to improve patient outcomes and enhance clinical processes when implemented thoughtfully into the clinical workflow. As the end users of AI-based symptom management models, nurses should be involved as content experts, beginning with model development and continuing through the design, integration, and evaluation of the model into workflows, to maximize both short-term implementation and long-term adoption. However, additional research is needed to identify which implementation strategies are effective at promoting the adoption and sustained use of AI-based symptom management models.

Limitations

We sought to elicit oncology nurses' initial thoughts on AI-based symptom prediction models. We should continue to inductively evaluate nurses' adoption of AI. Our exploration was limited by a small sample size and a homogenous population that was skewed by age (older) and education levels (high) that impacts the generalizability of our findings. This may be attributable to our convenience sampling approach and the fact that participants recommended other individuals who were recruited to participate, possibly introducing selection bias. Both the sample skew and homogeneity may have influenced the overall positive perceptions of an AI model for use in symptom management. Additionally, the use of unrecorded and note-based qualitative data analysis may have limited our ability to accurately assess content-level saturation; however, we believe that the detailed notes taken by interviewers permitted accurate assessment of content-level saturation. Finally, while we used the Rogers Diffusion Theory of Innovation to improve the descriptive analysis of the qualitative themes, it may limit our understanding of the responses and future work. Further work should survey a larger sample of nurses to understand oncology nurses' perceptions of AI symptom models and consider the impact of education levels on their views regarding AI. Additionally, future work should highlight the gaps in nurses' understanding of the application of AI in clinical care. The inclusion of end users in the design and testing of AI-based models facilitates adoption, and additional work should concentrate on and focus on implementation processes, which include user-centered design testing of best practices, such as alerting, alert visualization, and responses to care.

Conclusions

Overall, nurses showed a positive attitude toward the adoption of AI-based symptom models, particularly highlighting the perceived advantages of such models and their compatibility with nurses' goals of enhancing the patient experience. Proper use of AI symptom prediction models creates the opportunity to decrease the burden of patient reporting of cancer symptoms, improve clinician responsiveness, and enable prompt intervention to reduce unnecessary care and escalations. To facilitate the seamless integration of AI-based symptom models, thoughtful inclusive design strategies must include end users to test and modify transparent clinical models for long-term adoption.

Abstract

Background: Digital technology-based health care services like telemedicine and telenursing are expanding quickly globally. Although the use of telemedicine and telenursing has shown promise, there are a number of obstacles to overcome.

Objective: This study aimed to determine the experiences of stakeholders with using telenursing and telemedicine during and after the COVID-19 pandemic.

Methods: This study combined descriptive qualitative analysis using a focus group discussion (FGD) and validation using a review of the literature. The literature search used a convenience approach with the keywords benefits, advantages, disadvantages, obstacles, and constraints of telenursing or telemedicine to find relevant journal articles. Two FGDs were conducted during the COVID-19 period, namely 2020 - 2022, with the first FGD held in 2022. The second FGD was conducted in 2023 - 2024 to determine the implementation of telenursing and telemedicine during the recovery period, with data collection in 2024. The FGDs were conducted via the online Zoom platform, and a total of 23 participants were selected based on purposive sampling. People involved in the development and implementation of telemedicine or telenursing were included. Data analysis was conducted in 2 stages: the first using an inductive method, which was followed by triangulation using a deductive method. The results were verified and validated based on the reviewed literature.

Results: We identified three themes: (1) health care providers have experience using telemedicine/telenursing; (2) telemedicine and telenursing have many benefits; and (3) telemedicine and telenursing have 5M (method, man, money, material, and machine) factors that must be anticipated. Key statements were identified and validated, then matched with the literature review.

Conclusions: The benefits and barriers of telemedicine and telenursing were identified. For telemedicine to run smoothly, preparation of 5M elements is necessary. Implications for health care services necessitate the creation of operational guidelines for the implementation of telemedicine and telenursing.

(JMIR Nursing 2026;9:e90610) doi:10.2196/90610

KEYWORDS

human resources; 5M; method, man, money, material, and machine; telemedicine; telenursing; regulation

Introduction

The role of digital health technology in all countries grew rapidly during the COVID-19 pandemic. Telemedicine and telenursing, which provide remote service facilities and can reduce physical contact that causes transmission of the COVID-19 virus, were very important during the COVID-19 pandemic [1,2]. The use of telemedicine when treating patients with COVID-19 allows consultations and administering drugs without going to health facilities, strengthening the health system. This is beneficial for the handling of COVID-19 because it can reduce the number of COVID-19 exposures [3]. Some telemedicine and telenursing technologies were used in the

XSL•FO
RenderX

COVID-19 era for treatment consultations, monitoring, follow-up after hospitalization, providing counseling during isolation, and providing health education [4].

In Indonesia, telemedicine and telenursing are needed due to its archipelagic geography and numerous seas. Digital systems are essential for delivering services, as traveling to health care facilities can take more than 1 hour. Several studies provide evidence that telemedicine and telenursing are beneficial for increasing access and connecting urban and urban areas [5,6]. Telenursing can be used to direct when to take medications, to describe how to treat wounds, to help patient movement, and as a medium for health consultation for patients [5,7-9]. Facilitating the reach to more areas can save transportation and direct health care costs [10-14].

In line with the results of previous studies, telenursing can be used to monitor patients and provide coverage of services while reducing exposure to infection [10]. Several other studies also conveyed that telemedicine and telenursing can improve quality of life, reduce service costs, and be time efficient because patients do not have to go to health services; in addition, it can reduce the costs of consultation between health workers [11].

Since telenursing's readiness frequently affects success, a 5M (man, money, method, material, and machine) preparation strategy is crucial. This 5M strategy was developed to prepare for telenursing and telemedicine. Poor community literacy competency and inadequate infrastructure limit the use of telemedicine [12,14,15]. There are many obstacles to the use of telenursing and telemedicine, such as limited patient digital literacy [14,16], and a lack of facilities can decrease the enthusiasm for telemedicine after the COVID-19 era [13,14]. The absence of full regulations, such as a credentialing process for the telemedicine service provider industry, is an obstacle in Indonesia. A previous study stated that regulation was needed for telemedicine implementation. In addition, certification and credentialing for human resources who perform telemedicine practices are not available. The issue of patient data security and confidentiality is also present in Indonesian telehealth practices [12,13].

In some areas, the use of telehealth, including telemedicine and telenursing, decreased after the COVID-19 era due to patient preferences [14,17]. This online consultation model boomed in the COVID-19 era, but has gradually decreased since. Many consumers returned to direct services because they could meet directly with care providers such as doctors and nurses. According to prior research, a more accurate disease diagnosis, more accurate and better patient examination by a physician, and more accurate and better disease treatment are the primary reasons for selecting in-person appointments [17,18]. This study aimed to determine the experiences of stakeholders with using telenursing and telemedicine during and after the COVID-19 pandemic. The study also aimed to identify the readiness of 5M aspects to support telenursing implementation. The research results were expected to provide recommendations for the ideal implementation of telenursing and telemedicine.

Methods

Study Design

This study used a descriptive qualitative technique to investigate the perceptions of health stakeholders for managing the advantages of telemedicine and telenursing and to determine the weaknesses of 5M factors. In this study, we excluded market aspects and focused our evaluations on how workflows (methods), people, money, machines, and materials were executed.

The study results will provide recommendations for better telemedicine and telenursing implementation by conducting a synthesis that combines a literature review and descriptive qualitative analysis of focus group discussions (FGDs). We searched for journal articles using a convenience approach with the following keywords: benefits, advantages, disadvantages, 5M obstacles, and constraints of telenursing or telemedicine. We posed 4 questions regarding the use of telenursing and telemedicine during 2 data collection periods, namely during the final period of the COVID-19 pandemic (2022 - 2023) and after the recovery period (2024).

We conducted 2 FGDs. The first was held in 2022, to represent the COVID-19 period (2020 - 2022). The second FGD was conducted in 2024 to determine the implementation of telenursing and telemedicine during the recovery period (2023-2024). The FGDs were conducted via the online Zoom platform. Data collection was conducted twice to examine perspectives during and after the COVID-19 pandemic. After the COVID-19 pandemic, there was a tendency for patients to prefer direct care at health facilities.

The questions asked during the FGDs were almost the same, with the aim of understanding the perspectives, benefits, and potential challenges that arise during the implementation of telehealth. These questions were as follows: (1) Describe the telemedicine or telenursing services you have utilized. (2) What are the prospects for telemedicine and telenursing implementation? (3) Could you explain the shortcomings experienced and 5M factors when using telemedicine and telenursing? and (4) What do you hope to achieve by utilizing telemedicine or telenursing?

Participants and Approach to Their Selection

Data were gathered through semistructured FGD with policymakers, hospital organizations, medical doctors, nurses, and health care providers. Purposeful sampling was used to ensure representation across different occupations and demographic groups. Participants were invited by sending a letter of application to become a participant to hospitals, clinics, health centers and health worker associations. The organization then appointed the sections that would participate in the FGD according to the requested criteria, namely having experience in implementing digital health, including telemedicine or telenursing.

We selected 12 FGD participants in 2022 and 11 FGD participants in 2024 via purposive sampling. Ideally, the FGD participants would have been the same individuals, but this study had a weakness in that participants in the first FGD could

XSL•FO
RenderX

not participate in the second FGD. Participants in 2022 and 2024 were different people because they were sent by the target organizations according to the research objectives. Some differences in the participants were due to changes in personnel and tasks of the organization during the COVID-19 period. The professions of the participants were diverse, namely nurses, midwives, doctors, lecturers, medical recorders, lawyers, and others. Additionally, involving a variety of stakeholders was expected to help identify potential and 5M barriers to telemedicine and to develop targeted recommendations to address them effectively.

Data Collection

Response bias was possible because the data were gathered through focus group conversations, where individuals might alter their answers in reaction to what other group members think. To reduce prejudice, the facilitator gave each participant information at the outset so they may voice their opinions independently of other participants' experiences. At the conclusion of the conversation, each member had the opportunity to share personal experiences that had not been discussed. Saturation was reached when no new topics nor information surfaced from the focus groups. One way to reach data saturation is to ask whether there are any unresolved issues from the focus group.

The researcher's online Zoom account was used to conduct the FGD. Participants who were not speaking were muted to reduce noise while someone was speaking. Participants were invited to repeat what was said when the signal was clear again if signal interference was present. The atmosphere could be managed during the FGDs, and there were no issues with internet connectivity.

Analysis and Data Validity

Data analysis was conducted in 2 stages: (1) inductive method and (2) triangulation with the deductive method, which was verified and validated based on the reviewed literature.

In the first stage, the research team used an inductive content analysis on each communication from the FGD, which they verified without looking at the existing literature. Field comments were added to the transcribed audio data. To identify any writing errors and validate the comments made by the participants, the transcriptions were read twice. This methodical approach ensured that every facet of the data was carefully considered and comprehended, producing thorough and trustworthy results. The transcription stage was carried out immediately after the FGD was completed. The researcher re-examined all statements from participants in both FGDs. The transcription, transcribing, and coding processes in stages 1 and 2 were carried out in the same steps. The facilitator retrieved words by attaching parallel keywords, then grouped and compared all codes. From these grouped keywords, the principal researcher then discussed them with a research team consisting of 3 participants in the FGD who acted as field observers and research assistants. The keyword data were compared with the final field notes to gain consensus in order to obtain themes that ensured trustworthiness and transparency and were not biased toward only one researcher.

The researchers used a thematic approach to analyze qualitative data in 2022 and 2024. After obtaining initial codes, terms, and themes from the FGDs, we evaluated and reviewed these themes by comparing them with the entire dataset to ensure they accurately reflected the views of health care providers. During this stage, we analyzed the themes as they evolved across time periods, specifically comparing participants' telemedicine implementation during the peak of the COVID-19 pandemic in 2020 - 2022 with the subsequent postpandemic situation in 2023 - 2024. We then clearly defined and named each theme to establish its specific meaning and scope in relation to the research questions.

The information was then classified, extracted to identify significant statements, and analyzed to create meanings. After categorization, themes were developed from the data in each FGD. These themes were eventually reduced to codes and incorporated into a comprehensive analysis of the studied situation. The researchers counted the communication from participants in each phase of the FGD, grouped them by the same theme, and described them in the 2022 and 2024 FGD stages. In the end, the data are presented as study findings in the form of tables and discussion points.

In order to assure the rigor of our telemedicine FGD in 2022 and 2024, we undertook member checks to ensure credibility. In this study, we clarified remarks made by participants over the phone on the decrease in telemedicine use following the COVID-19 pandemic. Additionally, we performed peer debriefing by triangulating data from articles and national policies and addressing all themes. Additionally, we maintained confirmability by exercising researcher reflexivity and closely following the FGD guidelines, and we established dependability by guaranteeing the lack of researcher bias. Our FGD topics were cross-referenced against reputable peer-reviewed articles as part of our second strategy to ensure rigor. The triangulation stage involved analysis using a deductive approach, validating the existing themes with several previously conducted studies. This method aimed to compare existing findings with those in other studies to provide a comprehensive picture both abroad and domestically. This method was expected to provide better recommendations and a more comprehensive implementation of telenursing and telemedicine.

In the assessment of the overall readiness for telemedicine implementation, this study used triangulation by combining the results of the FGDs and theoretical foundations from journal articles synthesized through the keywords readiness, telenursing, or telemedicine. All relevant articles available as full text were read and analyzed using the telemedicine readiness approach of the 5M elements. The 5M dimensions identified in this literature review were aligned with qualitative themes extracted from the FGDs. The articles were found from the year 2005 to 2025 and from the Ministry of Health regulations in Indonesia. The articles and national regulations provided basic indicators and best practices for the 5M components; meanwhile, the FGD data offered a localized, real-world context regarding stakeholder perceptions and challenges. By cross-verifying the 2 datasets, we were able to comprehensively conclude the strengths, gaps, and readiness levels of facilities for adopting telemedicine or telenursing.

XSL•FO
RenderX

The weakness in this study's literature review is that it was not a systematic review but only used data from articles retrieved by searching research databases with the keywords telemedicine, telenursing, benefit, barrier, and COVID-19. We conducted a convenience search of journals through ProQuest and Google Scholar for articles published from 2005 through 2025. A total of 46 journal articles were analyzed and combined with the FGD results to obtain themes. Researchers reviewed the literature using unstructured (qualitative/narrative) and incidental data, involving the application of thematic and content analysis frameworks to synthesize diverse, nontraditional, and serendipitous sources. The steps included identifying core concepts through keyword extraction, underlying arguments, and key narratives. Coding was then performed, grouping insights into themes. Synthesis was then performed, connecting, comparing, and building themes. The Quality Rating System (QRS) consists of 21 explicit items covering study design, data collection, and analysis. It helps authors write better papers, assists reviewers with evaluation, and guides readers when appraising evidence, ensuring full clarity and trust in the study. Finally, the Standards for Reporting Qualitative Research (SRQR) checklist was used to improve the transparency of all aspects of the qualitative research [19].

Ethical Considerations

All participants provided written informed consent, and the participants were aware of the research goals, advantages, and methods. The team members maintained anonymity throughout the completion of the FGD, guaranteed confidentiality, and discussed their experiences with digital implementation. The authors adhere to ethical norms when publishing the improvement study's data by protecting both personal and organizational privacy and data confidentiality when implementing telemedicine and telenursing. This study was approved by the Ethical Board of the Faculty of Nursing, Universitas Indonesia: KET-138/UN2.F12.D1.2.1/PPM.00.02/2022 and KET 180/UN2.F12.D.1.2.1/PPM.00.02/2024.

Results

Attendance at focus groups has been an issue of concern, which was also identified in our research. FGDs were attended by 12 participants in 2022 and 11 participants in 2024 (Table 1). Participants included nurses, nurse practitioners, medical doctors, lecturers, and a lawyer. Verbatim responses were compiled per question and combined in participant groups in 2022 (code -22), and 2024 (code -24). After being delivered verbatim, at the end of the analysis, theme mapping was conducted for each question.

Participants' statements in the 2022 and 2024 FGDs were then grouped, resulting in three themes: (1) health care providers have experience using telemedicine/telenursing, (2) telemedicine and telenursing have many benefits, and (3) telemedicine and telenursing have 5M factors that must be anticipated. Complete participant statements and keywords were grouped and grouped into themes, as described in Table 2.

Table . Telenursing and telemedicine themes during and after the COVID-19 pandemic.

Themes and years	Supporting input
Health care providers have experience using telemedicine/telenursing.	
2022	• Terminology telenursing and telemedicine (P6) • Complement of digital transformation (P4; P6)
2024	• Telenursing part of telemedicine (P1) • Telemedicine and insurance (P10) • As digital transformation (P1)
Telemedicine and telenursing have benefits.	
2022	• Education for wound care (P2; P4) • Support for education and consultation (P1; P6; P7; P9) • Facilities for religious and spiritual studies (P1; P6; P9; P7) • Decrease direct cost (P9; P7) • Facilitating access and speeding up the consultation (P1; P6; P9; P7) • Consultation and education (P6; P7; P8) • Send medication to a patient in isolation (P2) • Decreasing virus transmission (P1; P2; P6; P7; P8) • Consultation during the pandemic (P2; P6; P7; P8) • Monitoring and follow-up (P4; P11)
2024	• Complement digital transformation (P1; P2; P3) • Consultation and education (P2; P3; P4; P8) • Facilitating access (P1; P8; P9) • Decrease cost for direct treatment (P9) • Referral from public health services to hospital (P4; P6) • Support for education, consultation, and disaster conditions (P4; P8; P9) • Education for wound care (P2:P4:P9)
Telemedicine and telenursing have 5M[a] factors that must be anticipated.	
Method factors	
2022	• Method of delivery (P1; P5; P11; P12) • Payment guide (P7; P10-11) • Security and privacy (P6; P10; P11; P3) • Ethical conduct guide (P6; P11) • Health services credentialing (P10; P5) • Satisfaction and comfort (P9) • Not for all, combination, education, follow-up care (P6; P10; P8) • Method: need caring (P1; P12; P5: P11)
2024	• Regulation (P1; P4; P9; P10) • Payment national guide (P1; P4) • Security and privacy (P1; P4) • Kind of services • Not for all services, education, follow-up care (P1; P8; P9; P11)
Man factors	
2022	• Competencies (P1; P5; P9; P7) • Credentialing for health provider (P10; P5) • Capabilities (P1; P3; P5; P6) • Training and socialization (P5; P1; P3; P6)
2024	• Competencies, training, and socialization (P1; P2; P3; P4; P9) • Capabilities (P1; P2; P3; P4; P9)
Money factors	
2022	• Training cost (P5; P1; P3; P6) • Infrastructure and investment (P8)
2024	• Training cost (P1; P2; P3; P9) • Infrastructure and investment (P4; P1; P2; P5; P7)

XSL•FO

Themes and years	Supporting input
Material and machine factors	
2022	• Infrastructure for integrated video calls and Zoom (P8; P10) • Access (P4; P7) • Network and teledevice (P8; P10; P11) • Health facility credentialing (P10; P5) • Integrated with EMR[b] (P10; P3)
2024	• Infrastructure: chat, AI[c], device, application, EMR (P4; P1; P2; P5; P7) • Network and teledevice (P7) • Integrated with EMR (P1)

[a]5M: people/man, methods, money, materials, and machines.

[b]EMR: electronic medical record.

[c]AI: artificial intelligence.

The first theme was "health care providers have experience using telemedicine/telenursing." Participants discussed that telenursing was part of telemedicine. The existence of telemedicine and telenursing is already largely known by stakeholders. FGD participants in both 2022 and 2024 familiar with telemedicine and telenursing that help with patient care used the technology. Some implemented it in hospitals, intensive care units, and health centers, as described in Textbox 1.

Textbox 1. Participant input supporting the "health care providers have experience using telemedicine/telenursing" theme.

- Terminology in the health regulation; telemedicine is a clinical service provided by a health service provider through or using information technology.; telenursing as a part of telemedicine (P1-24; P6-22).
- Previously, a telenursing and telemedicine for intensive care units were built in collaboration with the Japan International Cooperation Agency. It is no longer running (P8-24).
- Telemedicine in primary health care following Badan Penyelenggara Jaminan Sosial Kesehatan assurance (P10-24)
- Telemedicine or telenursing will complement the digital transformation in Indonesia (P4-22; P6-22; P1-24).
- It was explained that, in the future, there will be development of telenursing and telemedicine (P4-24).

The second theme was "telemedicine and telenursing have many benefits." The benefits of telemedicine and telenursing include increasing access to services. During the pandemic, it could help reduce the transmission of COVID-19. In addition, it can help with educational media, consultations, wound care, follow-up care, and spiritual care reinforcement. Participant inputs that represent this theme are shown in Textbox 2.

Textbox 2. Participant input supporting the "telemedicine and telenursing have many benefits" theme.

- Speed up consultations, especially during the COVID-19 pandemic (P1-22; P2-22; P6-22; P7-22; P8-22)
- Decreasing virus transmission during the COVID-19 pandemic; send drugs (P6-22; P7-22; P8-22; P2-22)
- Consultation, education (P6-22; P7-22; P8-22; P2-22; P2-24; P3-24; P4-24; P8-24)
- Telenursing will bring patients closer to nurses, facilitating access. The service is without walls (P1-22; P6-22; P9-22; P7-22; P1-24; P8-24; P9-24).
- Telenursing will decrease costs for direct treatment (P9-22; P7-22; P9-24).
- Make referrals easier from public health services to hospital (P4-24; P6-24)
- Telenursing can be used for long-distance wound care consultations. Consultations from the disaster location are also useful during disasters (P2-22; P7-22; P8-24).
- In addition to education, this application also facilities religious and spiritual studies (P1-22; P6-22; P9-22; P7-22).
- This is to support education for patients with wounds care (P2-24; P4-24; P9-24).
- Telenursing is very useful for monitoring and following up patients after being treated at the hospital (P4-22; P11-22).
- During COVID-19 virtual consultations, nurses first access their patients, then after being assessed, they are given education related to their nursing; they then consult a medical doctor. The doctor makes a diagnosis, then they are given a new prescription order to the pharmacy, and the medicine will be sent via application parties (P8-22).

XSL•FO
RenderX

The third theme was “telemedicine and telenursing have 5M factors that must be anticipated.” The weaknesses of telemedicine and telenursing were identified by participants. The main problem was the incomplete national regulations on service rules through technology, including payment. Human resource competence, connection, and infrastructure readiness were still an issue. Several participants said that it, especially telenursing, cannot be implemented entirely based on technology. Nursing care must still have contact with the patient as a manifestation of caring from nurses to patients.

The expectations of participants toward the implementation of telemedicine and telenursing were synthesized using the 5M approach, namely method, man, money, material, and machine. In the method category, management of telemedicine and telenursing is needed. This includes selecting services that can use tele/digital services, including education, monitoring, follow-up care, providing motivation, and spiritual aspects. Some services that require direct contact and diagnosis enforcement still require a dual-method model, namely direct and technology-based services. Moreover, telemedicine and telenursing services must also prioritize patient and family satisfaction and comfort. There is a need for health facility credentials to permit the delivery of a telemedicine or telenursing program. Human resources must also have the authority for technology-based services and to receive training to improve digital literacy. Money should be set aside specifically for infrastructure upgrades, for training to use the equipment, and to increase digital literacy. Participant input that represents this theme is described in Textbox 3.

Textbox 3. Participant input supporting the “telemedicine and telenursing have 5M (man, methods, money, materials, and machines) factors that must be anticipated” theme.

- I hope this telenursing will make it easier for patients to access it (P4-22; P7-22).
- The competencies that must be possessed by this telenursing; are specialist nurses allowed to do tele-nursing nursing or nurses with a minimum of S1 (Bachelor nursing) or D3 (diploma)? (P4-24; P9-22)
- Need credentials for human resources and health facilities that organize telemedicine (P10-22; P5-22)
- It is necessary to improve the human resource capabilities of both doctors and nurses; perhaps it needs to be socialized if there is an application…training cost (P5-22; P1-22; P3-22; P6-22; P1-24; P2-24; P3-24; P9-24).
- For telenursing method of delivery, not all care can be done by tele. Nurses need direct touch; caring becomes an issue when only via tele (P1-22; P12-22; P5-22, P11-22).
- What platform will be used in telemedicine or telenursing; must prepare it? Cost for infrastructure and investment (P4-24; P1-24; P2-24; P5-34; P7-24; P8-22)
- Network problems are not all good; not all areas have teledevices (P8-22; P10-22; P12-22; P11-22; P7-24).
- To data security, it must be integrated with electronic medical record (EMR; P10-22; P3-22; P1-24).
- Regulation must clear; payment must be managed by national regulation (P7-22; P11-22; P1-24; P4-24).
- We need to push for national guidelines for the implementation of telemedicine and telenursing (P10-22).
- Need professional ethical guidelines in using telenursing-based services (P6-22; P11-22)
- It’s not a clear condition. I've never seen the exact regulation, like payment regulations. But, as far as I know, already a regulation. I just haven't read it (P9-24; P10-24).
- Regulations regarding telenursing or telemedicine services and payments are not yet clear (P1-24; P4-24).
- Even though virtual is used, it must guarantee patient satisfaction and comfort (P9-22).
- Suggestions for telenursing should choose a type of service that can use digital technology. Monitoring, follow-up care, or education can be done with telenursing. This activity is still combined with direct meetings between nurses and patients (P6-22; P10-22; P8-22; P1-24; P8-24; P9-24; P11-24).
- Not all treatments can be done with telenursing such as wound care. Consultation and education can be done with telenursing or telemedicine (P1-22; P5-22; P11-22; P12-22).
- But it’s necessary to follow up on the patient’s condition, such as using video calls, Zoom to be able to carry out a more in-depth assessment (P8-22; P12-22).

Complete participant statements and keywords were grouped into themes, as described in Table 2.

Table 2 describes the keywords used in 2022 and 2024 that were compiled into themes derived from FGDs related to telenursing and telemedicine. There are differences in emphasis: in 2022, heavy focus was placed on the benefits of telenursing and telemedicine reducing the transmission of COVID-19, whereas in 2024, the benefits of telemedicine expanded to include access, education, and consultations. The 5M factors were described almost identically by the participants in 2022 and 2024. In this study, researchers also calculated keywords used to identify trends or provide support for themes and validated using incidental studies found in the literature (Table 3).

[a]5M: people/man, methods, money, materials, and machines.

Table 3 gives details of the analysis comparing the journal articles and the description of subthemes and themes. We also provide the percentage of participants who conveyed similar meanings of the sentences. All topics are represented in the theme table, which was built by combining the synthesis of the journal articles and participant statements. After understanding the advantages and disadvantages of telenursing, recommendations were made for the implementation of telemedicine. The recommendations were developed using the 5M approach (Figure 1).

XSL•FO
RenderX

Figure 1. Recommendation for better implementation of telemedicine and telenursing.

As shown in Figure 1, the method includes telemedicine and telenursing management, as well as the selection of tele/digital services that can be used, such as education, monitoring, follow-up care, motivation, and spiritual aspects. This represents a dual direct and indirect model using a technology-based service that still maintains direct contact for certain services such as diagnostic confirmation. Credentials for health care facilities authorized to conduct telemedicine or telenursing must be obtained from the health facility side. Patient service documentation must be arranged so that it securely uses electronic medical records (EMRs), which must be integrated with national data from SATU SEHAT Indonesia in the future. The availability of facilities including telemedicine equipment and internet connections must continue to be developed so that they can reach all Indonesian islands. Additionally, human resources must be in charge of technology-based services and undergo training to increase their digital literacy level.

Discussion

Principal Findings

This research explored the experiences of health care stakeholders using telemedicine and telenursing. We identified the following three themes: (1) health care providers have experience using telemedicine/telenursing, (2) telemedicine and telenursing have many benefits, and (3) telemedicine and telenursing have 5M factors that must be anticipated. The research results indicate that telemedicine has been implemented in Indonesia, and its use increased during the COVID-19 pandemic. Although some participants mentioned that the hospitals where they work had not yet implemented telemedicine, all participants were aware of the implementation of telemedicine. Telenursing is also one type of telemedicine

XSL•FO
RenderX

that is widely used by nurses for follow-up care, monitoring, wound care consultations, and providing motivation.

The results of the research analysis describe many benefits of telemedicine, especially considering Indonesia's archipelagic condition. Telemedicine itself is a health care service for remote examinations, diagnosis determination, and therapy administration remotely, aided by technology such as phones, video conferences, and other methods [2,7]. Differences in emphasis were observed: in 2022, the advantages of telenursing and telemedicine centered primarily on decreasing the transmission of COVID-19, whereas by 2024, the benefits of telemedicine had expanded to encompass access, education, and consultations. With the help of technology, access to services will be improved, and patients will be brought closer to health care services without having to go to hospitals or community health centers. This study supports the statement that telemedicine helps rural areas access health care services, in line with previous research [14,15,20,32].

The ability of technology to reach various rural areas means that telemedicine and telenursing can reduce both direct and indirect costs. This has also been conveyed by previous research, which states that, if consultations are conducted online, travel costs to the hospital can be saved; additionally, it will save indirect costs such as those caused by time inefficiency [14,21-23]. Another previous study also stated telestroke was a highly cost-effective strategy, which may enhance stroke care and improve favorable outcomes in patients in rural China [33].

In addition to the benefits, telemedicine also faces challenges in its implementation. The participants provided many recommendations to anticipate the 5M barriers to implementation. The obstacle of implementation failure must be addressed by creating national regulations related to telemedicine and telenursing [14]. In 2023, Indonesia started requiring the use of EMRs, which aims for data integration and interoperability toward one data called SATU SEHAT (ONE HEALTH) Indonesia [34]. Telemedicine and telenursing must also begin to be integrated into SATU SEHAT and become part of the digital transformation in the health sector. Policies ensuring the security and confidentiality of EMR data must be enforced. This is in accordance with the synthesis of studies stating that medical records must document telemedicine-based service results and that data security must be maintained [34,35].

Another recommendation regarding policy is that credentialing requirements must be established for telemedicine providers. Only institutions with permits are allowed to conduct telemedicine or telenursing. In Indonesia, a regulatory sandbox was required, and all electronic-based health care service providers should be registered and assessed for feasibility before implementing telemedicine [35]. So this policy can be implemented, the government must be encouraged to apply it according to the regulations [14,17,35]. In addition to the organizing bodies that must have permits, the human resources providing care must be credentialed and licensed to practice telemedicine or telenursing. Nurses and doctors who use technology must receive training to improve digital literacy [8,16,36]. This digital literacy is essential for optimal telenursing performance.

Barriers that need to be anticipated are also related to telemedicine facilities. Text, video, telephone, and AI-based consultation media must be developed thoroughly [21,37,38]. The use of video facilitates the interaction between nurses and patients. The use of video also allows health care workers to monitor patients' conditions, and decisions will be faster with the help of AI [5,39,40]. Unfortunately, sophisticated technology often becomes a barrier for patients who lack digital literacy. Many older adult patients and vulnerable individuals do not have the tools for telemedicine, which can hinder the development of telemedicine and telenursing [10,27,41]. In addition to the tools, network connections are not evenly distributed in every region. Therefore, previous research recommends that the government strengthen the network connections to ensure the successful implementation of telemedicine [12-14,42].

Not all care can be perfectly delivered through telemedicine. Some participants stated that they had to choose the type of service that could be provided through telenursing but still used a dual approach, namely face-to-face consultation followed by telenursing. Nurses, whose core responsibility is caring, must continue to prioritize care that consistently enhances satisfaction and comfort [8,29,43].

Patient and family preferences also significantly influence the success of telenursing. The paradox of telenursing and telemedicine, where there is no direct contact with health care personnel, means there is no physical touch, and the fear of misassessment often leads to hesitation in choosing the telemedicine method [18,26]. Therefore, it is recommended to maintain deep interactions [29] and enhance the sophistication of tools that can monitor patient conditions such as vital signs, for example, with heart rate monitors that automatically connect to servers [33,44]. Digital literacy education for the community must also be continuously strengthened so that the community increasingly understands the benefits of telenursing or telemedicine [24,28]. Improving digital literacy for the community can help them choose telemedicine and telenursing as an alternative support option for health care services [25]. Enhancing social impact is another recommendation for telemedicine success, as it can lessen apprehension about using new technology, particularly if the patient and health care practitioner have had favorable experiences with telemedicine [30]. The role of manager in encouraging the use of telemedicine is also very important, such as how managers controlled infections during COVID-19 by modifying services using technology. They must also be innovative and be role models in implementing telemedicine.

Limitations

This study used a mixed approach to analyze the qualitative descriptive results from the FGDs and journal articles. The weakness of this study is that the journal search used a convenience approach and was not part of a systematic review. The FGD participants in 2022 and 2024 were not the same people, so follow-up on the development of telenursing and telemedicine was not possible. Although it has weaknesses, the results of this study can be used as initial findings to improve the implementation of telemedicine in Indonesia and other

XSL•FO
RenderX

countries that have facilities, resources, and management that are almost the same as Indonesia. In future research, a systematic review and an in-depth interview method should be conducted.

Conclusion

These findings highlight the advantages and disadvantages of telemedicine and telenursing. We identified the following three themes from the study results: (1) health care providers have experience using telemedicine/telenursing, (2) telemedicine and telenursing have many benefits, and (3) telemedicine and telenursing have 5M factors that must be anticipated. The study's findings suggest that 5M factors should be prepared to implement telemedicine. These include procedures like payment plans, human resource credentials, and licensing rules for organizers. Enhancing digital literacy for the community and health professionals is also recommended, as well as creating a budget that focuses on infrastructure improvements and training for technology use and digital literacy. For telemedicine to function well, upgrading facilities and adding internet access are required. A service type must be selected to generate a service recommendation, which may involve a combination of telemedicine and in-person care, such as an initial in-person visit to a health care facility followed by monitoring via telenursing. Telenursing and telemedicine can help with activity monitoring, follow-up treatment, patient and family education and consultation, and incentive building. Enhancing patient satisfaction and care must be a priority when providing nursing care via telenursing. There are implications for governance; operational rules for telemedicine and telenursing must be developed, and health care providers must increase their digital literacy.

Acknowledgments

Thank you to all the participants, facilitators, and teams at the Working Group Ministry of Health, Faculty of Nursing Universitas Indonesia, and Digital Transformation Office (DTO) Ministry of Health who supported this study.

Funding

This work was supported by Grant for Policy Brief NKB-003/UN2.F12.D/HKP.01.03/2022 and a PUTI Q1-2024 NKB09/UN2.RST/HKP.05.00/ grant from Universitas Indonesia.

Conflicts of Interest

None declared.

Abstract

Background: Enhancing nursing students' awareness, attitudes, beliefs, and preparedness toward AI may help improve their health care knowledge and practice.

Objective: This study aimed to assess nursing students' attitudes, perceptions, self-efficacy, barriers, and anxiety, which influence their readiness to adopt AI in nursing practice.

Methods: This study used a cross-sectional, correlational design. Data were collected from 307 nursing internship students using an 8-part, self-administered questionnaire.

Results: Increased self-efficacy with computers was correlated with decreased barriers to accessing AI technology, lower computer anxiety scale scores (r=−0.27, P<.001 and r=−0.57, P<.001, respectively), and higher perceptions of using AI (r=0.27, P<.001). Meanwhile, nursing students' readiness to adopt AI in nursing practice was negatively associated with barriers to accessing AI technology (r=−0.20, P<.001) and positively associated with attitudes toward and perceptions of using AI (r=0.32, P<.001 and r=0.14, P=.01, respectively). Increased barriers to accessing AI technology were associated with negative attitudes toward AI and nursing students' perceptions of using AI (r=−0.34, P<.001 and r=−0.39, P<.001, respectively). A multilayer neural network model identified barriers (relative importance=0.27), attitudes (relative importance=0.16), and perceptions (relative importance=0.15) as the most significant predictors, while self-efficacy (relative importance=0.11) and anxiety (relative importance=0.07) showed smaller contributions, despite nonsignificant bivariate associations with nursing students' AI readiness. The model demonstrated strong predictive performance, achieving a low relative error of 0.62 in the training set. The stability and generalization ability of the model were supported by the training and testing set results, which yielded a training sum of squares error of 65.93 and a testing sum of squares error of 35.49, showing no signs of overfitting.

Conclusions: Several contributing factors influenced nursing students' readiness to embrace AI, with barriers, attitudes, and perceptions emerging as the most consistent, whereas self-efficacy and anxiety may play indirect roles. To improve the adoption of AI among nursing students, such factors should be dealt with in such educational programs; an interrelated adoption of AI in nursing practice is expounded as a more favorable environment.

Introduction

AI refers to a broad category of technology that empowers the hardware and software of computers to emulate the intelligent behavior of humans and perform at a level comparable to that of humans [1,2]. AI significantly enhances nursing care procedures, improves patient outcomes, and increases the effectiveness of care delivery [3,4]. It can enhance clinical decision-making by offering nurses insightful data and recommendations supported by evidence to inform patient care decisions [5]. AI can help nurses diagnose and treat patients more accurately by analyzing large amounts of data [6]. It can also support predictive analytics, improve patient monitoring, and help nurses identify the early warning signs of deterioration [3]. It is becoming more important for nursing education programs to prepare student nurses with the skills they need to use AI technology and to embrace its use in nursing practice as it develops [7-9]. The health care system requires this level of training in light of technological improvements and guarantees that nurses can use AI for patient benefits [8,10]. Enhancing nursing students' awareness, attitudes, beliefs, and preparedness toward AI may help improve their care [11-13]. To determine whether nursing students are prepared to incorporate AI-based technology into their academic work, it is important to examine various factors including their attitudes, perceptions, anxiety, self-efficacy, and barriers to the value of AI. Thus, it is critical to train nursing students to efficiently use AI technology and provide innovative health care delivery. In addition, nursing students' competencies need to assess their self-efficacy in using computers and their AI literacy to optimize the use of AI sources [14].

Although there has been an increase in the involvement of AI in nursing practice and education, researchers have focused on investigating nursing students' interest and readiness to adopt AI in the future [15,16]. One study revealed that nursing students' intention to use AI in the health care system can be affected by their positive attitudes and self-efficacy [17]. According to a study by Labrague et al [16], self-rated technological ability, knowledge of AI-powered technology, and perceived usage of AI in nursing practice all influenced Philippine nursing students' modest preparedness to incorporate AI into their practice. Accessibility issues with technology may also influence intentions and future behaviors [18,19]. These obstacles may be caused by a lack of computer proficiency, lack of understanding of AI, lack of money, or time constraints [20]. This study aimed to assess nursing students' attitudes, perceptions, self-efficacy, barriers, and anxiety that influence their readiness to adopt AI in nursing practice.

Methods

Design

A cross-sectional correlation design was used in this study.

Setting

This study was conducted among nursing students at the College of Nursing, Damanhour University, from November 2024 to January 2025. This faculty serves nursing students in the Beheira Governorate, the first accredited faculty member at Damanhour University. It consists of 4 years, with 1 year of internship training in hospitals. Students experience technology when dealing with online lectures, quizzes, and assignments. Nursing students are obligated to complete and pass both required and elective courses within a specific time frame to join the internship program. Students in the nursing program spend a year working under the supervision of faculty members in a variety of hospital settings as part of the internship program's primary goal of preparing them for real-world nursing.

Study Population and Sampling

The total number of nursing students engaged in the internship program was 1400. The required sample size of 302 internship students was calculated using the OpenEpi online calculator, version 3.01 [21], according to the criteria of 5% absolute precision and a 95% confidence level. A total of 350 internship students were invited to participate, and 307 (response rate: 87.7%) completed the survey. Students completing nursing internships with a minimum of 2 months of clinical experience were eligible to participate.

Tools of the Study

Data were collected using 8 sections of a self-administered questionnaire. The first section included the participants' sociodemographic details, including age, sex, level of education, previous year's grade, duration of internet use, awareness of AI in nursing practice and health care, previous AI knowledge, and sources of information. The second section assessed the technological abilities of nursing students, as adopted from Labrague et al [16], using a single question: "In general, how do you assess your technological proficiency?" to gauge the technological abilities of nursing students. On a 5-point Likert scale, which goes from "1=basic knowledge" to "5=expert," participants scored their level of technology competency; higher scores denote greater technological skill. As this is a single-item measure, the original study established the reliability of the instrument using test-retest reliability (r=0.910) [16]. Likewise, this study demonstrated excellent test-retest reliability (r=0.902), consistent with recommendations that test-retest reliability is an appropriate method for evaluating the reliability of single-item measures [22,23].

The third section, developed by Knezek [24], assessed nursing students' self-efficacy using computers. It consists of 8 self-reported questions, with a 4-point Likert scale ranging from 0 (strongly disagree) to 3 (strongly agree), and 6 items that are reverse-scored. The total rating ranges from 0 to 24, with higher scores indicating better computer self-efficacy. Although this scale was originally developed prior to the emergence of contemporary AI technologies, it assesses general computer self-efficacy, which is considered a foundational determinant of an individual's ability to engage with and adapt to new digital tools including AI-based systems. The questionnaire was tested for reliability with a Cronbach α of 0.801 [24]. In this study, the reliability of the scale was confirmed by Cronbach α of 0.875.

The fourth part assessed nursing students' readiness to adopt AI using a 5-item scale originally developed by Ayanwale et

XSL•FO
RenderX

al [25]. In this study, the scale was adopted based on its prior modification and application among nursing students by Labrague et al [16]. To enhance its relevance to the nursing education context, Labrague et al [16] modified the original teacher-oriented items by replacing the term "teach" with "learn," "class" with "nursing practice," and "teaching in class" with "nursing curriculum." These contextual modifications ensured that the scale more accurately reflected AI readiness among nursing students, while preserving the conceptual framework of the original instrument [16]. It consists of 5 self-reported questions to assess nursing students' readiness to adopt AI in nursing practice. Each question is scored on a 5-point Likert scale ranging from "strongly disagree" (1) to "strongly agree" (5). Higher scores indicate greater willingness to use AI-based technologies. We divided this number by the number of items and added the average score for each item to determine the final score. Internal consistency was assessed using Cronbach α, which yielded a value of 0.920. The reliability of the scale was confirmed using Cronbach α, which was 0.937.

The fifth part assessed students' perceptions of the use of AI using an 11-item scale developed by Swan [26]. Participants used a 5-point Likert scale, with 1 denoting "strongly disagree" and 5 denoting "strongly agree," to score their level of agreement. The implementation and use of AI technology in nursing practice were perceived more favorably by those who scored higher on this scale. The reliability of the scale was established with a Cronbach α of 0.900 [26]. In this study, the reliability of the scale was confirmed by Cronbach α, which was 0.836.

The sixth part, adopted from Ayanwale et al [25], was used to assess nursing students' perceived barriers to using AI technology. Each item is scored on a 5-point Likert scale ranging from "strongly disagree" (1) to "strongly agree" (5). Higher ratings suggested that participants felt there were more obstacles to using the AI-powered solutions. The internal consistency of the scale, as determined by Cronbach α, was 0.880 [25]. In this study, the reliability of the scale was confirmed by Cronbach α, which was 0.894.

The seventh part assessed nursing students' attitudes toward AI, which was developed by Schepman and Rodway [27]. The questionnaire consisted of 20 self-report questions on a 5-point Likert scale, with a higher score indicating a positive attitude toward AI [27]. The reliability of the scale was established with a Cronbach α of 0.930 [28]. In this study, the reliability of the scale was confirmed by Cronbach α, which was 0.899.

The eighth part was the Short Computer Anxiety Scale, which was adopted from Lester et al [29]. A 6-item measure was developed that included questions on computer confidence. Of these, 2 items showed computing comfort, whereas the other 4 items showed shortcomings. Internal reliability was confirmed by Cronbach α of 0.760 [29]. In this study, the reliability of the scale was confirmed by Cronbach α, which was 0.844. All study instruments were administered in their original English versions, since English is the official language of instruction for internship nursing students. Therefore, no translation procedure was required.

Ethical Considerations

This study was approved by the Damanhour Research Ethics Committee (Approval 2024 - 030685). Following an explanation of the study's purpose, all the respondents provided written informed consent. The participants were made aware of their freedom to leave the study at any moment and without any explanation. Confidentiality of the respondents' data and anonymity were guaranteed. During their breaks, all intended nursing students received an invitation to participate in the study, as well as informed consent forms and questionnaires.

Data Analysis

SPSS statistics (version 26, IBM Corp) was used to evaluate the data, with a significance level of less than .05. While the mean and SD are used to summarize regularly distributed continuous data, frequencies and percentages were used to show categorical data. Histogram and statistical tests (Shapiro-Wilk and Kolmogorov-Smirnov tests) were used to determine whether the data were normal. The data were deemed to be normally distributed because the *P* values of these tests were higher than .05. One-way ANOVA (for more than 2 groups) and 2-tailed independent-sample *t* tests (for 2 groups) were used to examine the association between nursing students' attributes and overall scores. Pearson correlation coefficients were used to determine the correlations between variables. A multilayer perceptron neural network was used to predict nursing students' readiness to use AI in nursing practice. The network architecture consisted of 3 interconnected layers: an input layer, a single hidden layer, and an output layer. The input layer comprised categorical demographic factors (automatically dummy-coded into distinct operational units covering age categories, sex, study levels, internet duration, previous semester grade point average [GPA], and technological proficiency levels) and continuous variables (computer self-efficacy, perception, attitude, and computer anxiety). Of the 307 participants, the dataset was randomly partitioned into training (n=215, 70.0%) and testing (n=92, 29.9%) sets to prevent overfitting. The model was trained and its performance was evaluated using the sum of squares error (SSE) and relative error. The choice of a multilayer perceptron neural network was justified by its capacity to describe complicated nonlinear relationships and interactions between factors that typical linear regression models may not sufficiently capture. While regression and structural equation modeling are frequently used and have good interpretability, they often assume linearity and may be limited in capturing higher-order interactions between psychological and environmental variables [30].

Results

Participant Characteristics

The sample (N=307) distributions are presented in Table 1. It reveals that the mean age of undergraduate nursing students was 20.0 (SD 1.05) years, with 69.4% (n=213) being 20 years or younger. Most students were female (n=185, 60.3%). Most nursing students (n=143, 46.6%) had an excellent GPA during the semester, and 44.6% (n=137) had a moderate level of technology proficiency. While a clear majority of undergraduate nursing students (n=219, 71.3%) possessed general, baseline

XSL•FO
RenderX

knowledge about AI as a broad consumer concept, a substantially smaller proportion (n=126, 41.0%) demonstrated awareness regarding the specific, practical applications of AI within health care systems.

Table . Demographic characteristics of undergraduate nursing students (N=307).

Demographic characteristics	Values, n (%)

Students aged over 20 years, studying at the fourth level, and having an excellent GPA in the last semester had a higher mean self-efficacy with computers, with statistically significant *P* values of .04, .04, and .001, respectively. Nursing students' readiness to adopt AI in nursing practice was higher among male students, those with excellent technological proficiency, those aware of AI use in health care and nursing care, and those with prior knowledge of AI, with statistically significant *P* values of .02, <.001, <.001, <.001, and <.001, respectively.

Nursing students' perception of AI had a higher mean score among those aware of AI's use in health care and nursing care, with a statistically significant *P* value of <.001. However, barriers to accessing AI technology were higher among students at the fourth level, with a statistically significant *P* value of .006. Nursing students' attitudes toward AI were more positive among those with excellent technological proficiency, those aware of AI's use in health care and nursing care, and those with prior knowledge about AI, with statistically significant *P* values of .04, .03, .008, and <.001, respectively. Finally, computer anxiety was higher among students aged 20 years or younger and those with fair GPAs in the last semester, with statistically significant *P* values of .01 and <.001, respectively. Further details are provided in Table 2.

[a]GPA: grade point average.

Increased self-efficacy with computers was correlated with decreased barriers to accessing AI technology, lower computer anxiety scale scores (r=−0.27, P<.001 and r=−-0.568, P<.001, respectively), and an increase in the perception of using AI (r=0.27, P<.001). Meanwhile, nursing students' readiness to adopt AI in nursing practice was negatively associated with barriers to accessing AI technology (r=−0.20, P<.001) and positively associated with attitudes toward and perceptions of using AI (r=0.32, P<.001 and r=0.14, P=.01, respectively). An increase in barriers to accessing AI technology was associated with a negative attitude toward AI and the perception of using AI by nursing students (r=−0.34, P<.001 and r=−0.39, P<.001, respectively), as shown in Table 3.

Table . The correlation among nursing internship students' readiness, self-efficacy, barriers, attitudes, perceptions, and anxiety to use AI.

Predictors of Nursing Internship Students' Readiness to Use AI

A multilayer neural network was used to predict nursing internship students' readiness to adopt AI, based on specified independent factors. The model identified barriers (relative importance=0.27), attitudes (relative importance=0.16), and perceptions (relative importance=0.15) as the strongest predictors of readiness. Self-efficacy (relative importance=0.11) and anxiety (relative importance=0.07) demonstrated comparatively smaller contributions despite their nonsignificant bivariate correlations with readiness. The findings shown in Figure 1 suggest that these factors collectively influenced nurses' openness to AI integration. The model demonstrated strong predictive validity, minimized error profiles, and high stability. While the training SSE was 65.93, the model achieved a low training relative error of 0.62, indicating high explanatory adequacy. The generalization and predictive ability of the network were confirmed by a testing SSE of 35.49 and a low testing relative error, establishing that the model was structurally stable and free from overfitting constraints.

Discussion

Principal Findings

This study aimed to assess how nursing students' attitudes, perceptions, self-efficacy, barriers, and anxiety influenced their readiness to adopt AI in nursing practice. The readiness of nursing students to incorporate AI in their practice is influenced by several factors, such as gender, technology skills, knowledge of the applicability of AI, and most importantly, knowledge background. Comprehensively addressing these factors through oriented teaching may equip nursing students with better ways to incorporate AI into their future practice and consequently enhance patient outcomes. Students aged over 20 years, studying at the fourth level, and having excellent GPAs in the last semester had higher mean self-efficacy with computers.

The readiness of nursing students to adopt AI in nursing practice was higher among male students, those with excellent technological proficiency, those aware of the use of AI in health care and nursing care, and those with prior knowledge of AI. Additionally, students with significant technological abilities tend to be more self-assured in their capacity to study and apply technologies such as AI, which has been clearly linked to their preparedness to embrace AI in nursing practice [31]. According to previous studies, male students are more likely to be ready to operate with AI than female students [31,32]. This is likely due to sociocultural factors that encourage males to take an interest in technological aspects and be less risk averse [32].

Nursing students' perceptions of AI had a higher mean score among those who were aware of the use of AI in health care and nursing care. However, barriers to accessing AI technology were higher among students in the fourth level. This suggests that nursing students who are familiar with the application of AI in the health sector may tend to have favorable sentiments toward it. However, especially during the graduate year, fourth-year students may not be able to access and use AI technology for reasons such as graduation pressure, insufficient time, and resources. Students exposed to further uses of AI in a clinical environment develop a more favorable attitude toward AI [33]. Nevertheless, as many positive perceptions arise as a result of awareness, obstacles to the appreciation of AI technology are a real source of concern, mostly for fourth-year undergraduate nurses. Fourth-year students may experience increased academic and career-related pressures, which could contribute to perceived barriers to engaging in AI technologies. This is in line with those who argue that, due to the underdevelopment of certain components of nursing education programs, such as health informatics and AI incorporating education, feelings of inferiority may arise and inhibit students' ability to use these technologies [34]. This educational gap may contribute to the barriers experienced by these students, as they may not feel adequately prepared to engage with AI technologies in clinical settings.

Nursing students' attitudes toward AI were more positive among those with excellent technological proficiency, those aware of AI's use in health care and nursing care, and those with prior knowledge of AI. Additionally, computer anxiety was higher among students aged 20 years or younger and among those with a fair GPA in the previous semester. This finding indicates that younger nursing students may experience greater apprehension when using computer technologies, highlighting the importance of early exposure to digital technologies and targeted educational support to enhance confidence and reduce technology-related anxiety. Owing to the increasing integration of AI worldwide, there is a dire need for nursing education that integrates AI knowledge to enhance the willingness of technology-based students [34]. It is also pertinent to note that awareness of the application of these technologies among nursing students also has an impact on their attitudes toward nursing. Previous studies have noted that students and professionals perceive AI to be more positivistic and feasible if they are aware of implications such as improved patient outcomes and decision-making [11,17]. Considering the prospects of AI in health care, it is essential to focus on educational activities that will allow future nurses to fully apply this knowledge in practice.

Meanwhile, nursing students' readiness to adopt AI in nursing practice was associated with fewer barriers to accessing AI technology, a more positive attitude toward AI, and a more positive perception of AI use. Greater familiarity with AI implementation was associated with more favorable attitudes toward AI technology, suggesting that increased exposure to and experience with AI may enhance students' acceptance of and confidence in using these technologies. These students were confirmed to be more positive about AI technologies and wanted to use them in their work [17,35]. From this, one can deduce that attention directed toward the progression of students' understanding of AI leads to an increased possibility of supporting positive change.

In contrast, high-level barriers to entering AI technology correlate with negative attitudes toward and perceptions of AI. For instance, nursing students who do not have easy access to AI tools may develop negative feelings, such as anxiety and negligence toward these technologies, which could discourage them from using them. This was consistent with a study conducted by Chen et al [36] in which perceived barriers were shown to reduce students' intent to engage in AI-related activities. In addition, this study highlights the need to overcome these barriers because students' attitudes toward AI are important for the acceptance and subsequent use of AI-powered applications in nursing [37]. This study used neural network modeling to ascertain the participants' AI adoption styles. There was a higher degree of accuracy in predicting readiness, with barriers, attitudes, perceptions, self-efficacy, and anxiety emerging as the top 5 manifest variables. In the case of readiness, there were also variables such as lack of access to AI technology, attitudes toward AI technology, beliefs about the usefulness of the technology, feelings of self-efficacy, and feelings of anxiety about the new technology. AI technology is positively and directly associated with perceptions of usefulness [20]. For example, it has been reported that nursing students' perceptions of AI technologies predict more positive attitudes toward the use of AI in nursing practice [17]. Indeed, training and support remove barriers and improve self-efficacy, thereby increasing the propensity to use AI [38]. Obenza et al [39] supported the notion that self-efficacy is an important determinant of individuals' willingness and confidence in

XSL•FO
RenderX

adopting emerging technologies. There are various estimations among nursing students regarding the implementation of AI when providing nursing care, and these vary in the adoption of AI owing to their attitudes and concerning factors. For instance, high perceived barriers to using AI technology tend to correlate negatively with positive feelings toward AI and the perception of its usefulness. In cases where nursing students possess barriers such as poor orientation and deficit of resources or scanty institutional support, they are likely to develop a certain disbelief in the usage of these AI-based tools. In such cases, anxiety about these problems is more likely to arise, which, according to [17], is negatively related to self-efficacy and willingness to accept changes in practices, including new technologies [17] in a negative sense. However, because of this anxiety, there is a high chance that students will be reluctant to use AI, which will lead to a negative attitude toward the adoption of new technology, which is likely to result in a negative loop, as pointed out [40]. Therefore, it is essential to address students' anxiety regarding AI to eliminate this negative loop and establish better interactions between nursing students and their modern technologies.

Despite the contribution of self-efficacy and anxiety to the neural network model, they did not correlate substantially with readiness in bivariate studies. This disparity may be explained by the capacity of neural networks to identify interaction effects and nonlinear interactions that are missed by straightforward correlations. Therefore, rather than being direct indicators of preparedness, their involvement should be carefully understood as indirect or context dependent. Self-efficacy is an important determinant of nursing students' perceptions of AI. A recent study indicated that students with greater self-efficacy regarding AI tend to approach and use AI technologies more positively [39]. It has been noted that self-efficacy is an important variable that affects the use of any technology, suggesting that students with such self-efficacy will be able to break through barriers and embrace new technology optimization [41]. Therefore, if the root causes of low self-efficacy concerning AI use in nursing practice are addressed with appropriate educational measures, there is a high likelihood that nurses will accept and use this technology while performing their duties. When self-efficacy is improved through adequate training programs and AI barriers are uplifted, nursing teachers can positively alter students' attitudes toward using AI. This approach also resonates with an earlier research suggestion that health care professionals should work together to facilitate effective integration of AI technologies into nursing practice [42]. Furthermore, the literature highlights the need to consider students' perceptions and attitudes toward AI. Anxiety factors, such as fear of incomprehension and subordination, are negatively influenced by the intention to use AI in nursing students [17]. Filling students' minds with information on the availability and advantages of AI technologies can increase their acceptance of and intention to use such tools. This is especially pertinent for nursing education, where incorporating AI into curricula could help students better comprehend it and decrease the fear associated with its application. However, the use of self-reported measures increases the risk of social desirability effects and common method bias, which could exaggerate the observed correlations between variables. The correlations may have been overstated because multiple categories (such as attitudes, self-efficacy, and perception) were measured at a single time point using the same methodology. The prediction performance of a neural network model may also be affected by inflation. Therefore, the strength of this relationship should be cautiously interpreted.

Limitations

Despite revealing some important information, the limitations of this study include country restrictions, use of self-reporting methods, use of only survey instruments, a lack of emphasis on ethical and cultural dimensions, the absence of tools within the study that might be needed, absence of data regarding AI use by students, and consideration of only short-term issues. To mitigate or even eliminate such limitations, it is recommended that future studies cover more, use what is available, relate the variables, detail ethics and cultures, check the clients' tools, look for students' embedment in AI, and assess their anxiety at a distance. This helps to expand the knowledge of how nursing students perceive AI in their future practice and helps form clinically effective approaches to the integration of AI into nursing practice. Although the AI readiness scale was previously updated for nursing students, it was originally designed for different professional groups. In addition, the instruments used in this study were originally developed and validated in different cultural contexts. Although administered in English, the absence of formal cross-cultural validation in the study population may have affected the generalizability and cultural equivalence of the findings. Additionally, the use of a neural network model, which is advantageous for prediction, limits interpretability compared to traditional statistical methods, which may affect the explanatory depth of the findings. Moreover, this study relied solely on self-reported data, which are susceptible to frequent method bias and social desirability effects. These biases may result in inflated effect sizes and overestimation of correlations between variables, as well as potentially improve model prediction accuracy. To avoid these biases, future research should use objective metrics, multiple data sources, or longitudinal approaches.

Implications for Nursing

Nursing students' competence in using their technological knowledge and skills to adopt and implement AI in their careers is explained by their positive attitudes toward and understanding of the benefits of AI. However, factors such as anxiety and limited access can reduce competence. To solve these problems, it is necessary to embed AI in nursing education, provide practical experience, eliminate fear, change public perception, and highlight its benefits. Furthermore, AI education should address ethical and cultural issues explicitly. To guarantee ethical use, issues such as data privacy, algorithmic bias, patient safety, and cultural sensitivity in AI-supported decision-making are crucial. Educational practices should be context-sensitive and prioritize fairness and accessibility due to differences in access to technology and institutional resources. Such integration will prepare future nurses to accept AI in their practice to advance the level of care patients receive in the health care system.

XSL•FO
RenderX

Conclusions

Several contributing factors influence nursing students' readiness to embrace AI, with barriers, attitudes, and perceptions emerging as the most consistent factors, while self-efficacy and anxiety may play indirect roles. The receptive attitudes of students with more skills, awareness, computer proficiency, and positive beliefs have encouraged the use of AI. Conversely, barriers, particularly higher levels of anxiety among younger students (≤20 y) and those with a lower GPA, were associated with lower readiness to use AI. A neural network model affirms the effects of various factors in predicting readiness to embrace AI. Creating a supportive educational environment that fosters AI readiness, self-efficacy, and positive attitudes toward AI may facilitate appropriate integration of AI into nursing education and future clinical practice.

Acknowledgments

We would like to thank all nursing internship students who participated in this study. The authors confirm that no generative AI tools were used in the preparation of the article.

Abstract

Background: Daytime urinary incontinence is a common childhood condition that can persist into adolescence, and it is associated with psychological distress, social and educational difficulties, and an increased risk of later mental disorders. The co-designed smartphone app "URApp" was developed in partnership with young people aged 10 to 18 years to support their self-management of bladder symptoms, but it is not yet used by community pediatric continence clinics to facilitate ongoing patient bladder training.

Objective: The study aims to understand the barriers and facilitators to embedding a digital health intervention (URApp) designed to aid adherence to bladder training in children and young people with daytime urinary incontinence in community pediatric continence clinics.

Methods: We conducted a mixed methods process evaluation using the Normalization Measure Development (NoMAD) questionnaire at 4 time points to measure behavior change in nursing teams at 6, 12, and 18 weeks. Teams' responses to questionnaire items were summarized as median scores and plotted at each time point using petal plots. Qualitative data were collected through focus groups and interviews and analyzed, drawing upon thematic analysis.

Results: Twenty pediatric continence nurses from 5 National Health Service community pediatric continence clinics in England were recruited through purposive maximum variation sampling. URApp was well-received, and nurses were positive about introducing it to patients and felt that URApp's functionality aligned with existing bladder training provided by National Health Service community clinics. Nurses reported that URApp was easy to introduce, age-appropriate for children aged 10 to 18 years, and accessible to patients with neurodivergent conditions. However, community teams found integration into existing care pathways challenging and did not fully use URApp for urotherapy and bladder diary data collection. Teams lacked confidence in changing from paper to electronic bladder diaries, and although they were positive about young people taking ownership of their bladder condition, they struggled to encourage URApp uptake and were concerned about the lack of parental oversight of bladder diary data in URApp. Successful uptake and patient engagement with URApp were also negatively impacted by barriers in the school environment, such as lack of access to toilets and smartphones.

Conclusions: The successful integration of URApp into community pediatric continence clinics requires cultural change in schools regarding toilet access and healthy drinking. Future implementation of URApp into existing clinical care pathways will need to consider how electronic bladder diary data from URApp can be used more effectively by clinical teams, in partnership with patients and their parents/carers to facilitate the shift from analog to a "digital-first health service."

Introduction

Daytime urinary incontinence (UI), the involuntary leakage of urine during the day, is a common child health problem that can persist into adolescence. International prevalence estimates of UI vary across studies due to differing definitions, but approximately 5% to 10% of school-aged children experience daytime UI, with prevalence declining to around 1% to 3% during adolescence [1]. Similar patterns have been reported in UK cohort studies, demonstrating that continence problems persist into adolescence for a clinically important minority of young people [2]. There is robust evidence that the prevalence of daytime UI is higher among girls (4.2% of females and 1.3% of males) at the age of 14 years [3-5]. Daytime UI in children and young people (hereafter referred to as young people) leads to psychological distress, social isolation, adverse impacts on education, and negative self-beliefs such as "feeling like an outsider" [6]; young people with UI are at increased risk of mental disorders in early adulthood [7,8]. Most cases of UI in children and adolescents are not due to underlying neurological or anatomical abnormalities, and the causes are unknown [7]. Despite the prevalence and adverse impacts of UI, most young people feel that they are not adequately supported by current services [9-11].

There are huge variations across the United Kingdom in pediatric continence service provision, and demand on these already overstretched services has increased since the COVID-19 pandemic [12]. Bladder training (standard urotherapy) is a behavior modification intervention that aims to correct bladder filling and voiding function [13]. It is an established conservative first-line intervention for UI that is recommended by the National Health Service (NHS) [14], charities supporting people affected by incontinence (ERIC [The Children's Bladder and Bowel Charity] and Bladder and Bowel, United Kingdom), and the International Children's Continence Society [15,16]. Bladder training involves establishing a regular schedule of fluid intake and timed toileting to improve the bladder function and reduce UI [13]. Bladder training can be effective, but success strongly depends on self-motivation, commitment, and ongoing clinical support [9,17]. Young people with UI often feel pessimistic about their prognosis and find it challenging to adhere to bladder training [9]. Treatment failure has cost implications for the NHS and threatens the mental well-being and academic attainment of young people [6,7,9,18,19].

Our research with young people with UI found that they have a strong desire to be involved in decisions about their treatment and to feel supported in self-managing their bladder symptoms [9]. In response to this, we co-designed the smartphone app "URApp" in partnership with young people aged 10 to 18 years [20]. URApp's core functions are based on existing bladder training approaches [13,21] and on empirical evidence about behavior change techniques to improve adherence [22-25]. These include techniques such as goal setting and reviewing, action planning, personalized feedback, and rewards to aid motivation to adhere to bladder training and to help young people work toward a personalized drinking goal. URApp provides discreet reminders for toilet visits and drinking; allows users to record fluid intake, frequency of toilet visits, and urine volume output; and provides charts to track progress, and it includes a diary to record other useful information such as wetting accidents, mood, types of drinks, or stressful events.

In August 2024, URApp was updated to allow users to export a bladder diary to share with their clinic team by text or email; click on *View the App Guide* [20]. Young people involved in the development and formative evaluation of URApp reported that it was acceptable, usable, engaging, and effective in supporting their drinking and toilet schedules, with many requesting to continue using the app beyond the study [26]. Health care professionals working in secondary care settings also reported that URApp was clinically appropriate and aligned with the guidelines for current bladder training and would use it within their own clinics [26].

Despite URApp already being recommended and used by some health care professionals in pediatric continence care [27], it had not yet been evaluated in community pediatric continence care settings. Digital health interventions, including smartphone apps, could facilitate the shifting of care from hospital to community and from analog/paper-based processes by providing continuous digital support, empowering patients to be active participants in their care, and digitizing patient information for health care professionals, in line with the NHS 10-year health plan.

The aim of the current study was to conduct a process evaluation of URApp in pediatric continence clinics to understand how it is embedded into usual care. We gathered evidence to understand the feasibility and practicalities of embedding URApp in this real-world setting, identifying barriers and facilitators to implementation.

Methods

Study Design

This process evaluation used a mixed methods approach based on Normalization Process Theory (NPT). NPT is a framework used to guide the implementation and evaluation of complex interventions [28-30] and to understand how staff routinely incorporate a complex intervention into practice in a specific setting [31]. The Normalization Measure Development (NoMAD) questionnaire [32,33] operationalizes NPT across its 4 constructs: coherence, cognitive participation, collective action, and reflexive monitoring. Coherence refers to key stakeholders' understanding of and opinions about an intervention. Cognitive participation involves stakeholders' engagement with the intervention. Collective action involves putting the intervention into practice, and reflexive monitoring focuses on stakeholders' appraisal of the intervention and its effects [28].

Participant Characteristics

Pediatric continence nurses who introduced bladder training to young people aged 10 years and older in Children's Community Continence Services were eligible to participate.

XSL•FO
RenderX

Study Setting, Sample, and Recruitment

Children's Community Continence Services are Tier 2 community specialist services comprising nurse-led, multidisciplinary teams that provide more specialized assessment and management of bladder and bowel issues in young people. They aim to reduce unnecessary referrals to secondary care. Clinical coapplicants DR and JC assisted with identifying sites in different regions of England serving young people from diverse socioeconomic and ethnic backgrounds. URApp was not routinely embedded within participating Children's Community Continence Services before the study. As part of this process evaluation, teams were asked to familiarize themselves with URApp and were encouraged to offer it to eligible young people receiving bladder training during the 18-week study period. Decisions about whether and how URApp was used with individual patients remained at the discretion of pediatric continence nurses. Therefore, the study evaluated the implementation and integration of URApp into routine practice rather than testing a mandated implementation protocol.

We recruited Children's Community Continence Service nurses from 5 centers to provide a purposive maximum variation sample of 20 participants. DR distributed the study advert to the lead nurse at each site via email (Multimedia Appendix 1), who provided consent to be contacted by LB if interested in finding out more about the study. LB emailed the participant information sheet to each interested site and provided further information at an online meeting. NHS staff completed consent forms via REDCap (Vanderbilt University), a secure encrypted web application for building and managing online surveys and databases [34,35]. All participating team members were asked to familiarize themselves with URApp using *View the App Guide* and by downloading URApp onto a mobile device [20].

Data Collection and Analysis

Staff completed an online NoMAD questionnaire (Multimedia Appendix 2) via REDCap at baseline and 6, 12, and 18 weeks. The NoMAD questionnaire is a set of 20 questions for assessing implementation processes among participants directly involved in implementing complex interventions in health care [32,33]. Staff at each site were also invited to take part in focus groups or interviews. Focus groups and interviews (lasting around 30 - 45 min) were conducted online via Teams, audio-recorded with consent from participants, and transcribed, and data were deidentified. A topic guide (Multimedia Appendix 3) was developed in consultation with the clinical coapplicants. The topic guide drew on the NPT theory and had the flexibility to explore teams' NoMAD questionnaire responses (eg, if there was "low agreement" with NPT subconstructs at a particular site/time point).

Responses to NoMAD items were analyzed descriptively as follows: "strongly agree" and "agree" were interpreted as "high agreement" (5 and 4), "Neither agree nor disagree" as a "neutral" response (3), and "disagree" and "strongly disagree" as "low agreement" (2 and 1). NoMAD item-10 was reverse-coded so that the higher value indicated more agreement for ease of interpretation. Measures of the "normalization" of practice from the NoMAD questionnaires were summarized as median scores and plotted at each time point using petal plots. Higher agreement with NPT subconstructs and better integration of an intervention are characterized by more uniform "petals," closer to the outer limits of each petal plot (see Multimedia Appendix 4, Figures SA-SE, petal plots). Qualitative data analysis used the NVivo software (version 14; Lumivero) to organize data and drew on reflexive thematic analysis [36] with a deductive approach to explore how data fitted with NPT constructs and subconstructs. NoMAD outputs were cross-referenced with qualitative data to gain an in-depth understanding of the optimization of URApp in community clinic settings.

Patient and Public Involvement

The original idea for developing URApp came from our previous research with young people with UI, who told us that they needed more support to manage their symptoms [26] and felt they were not adequately supported by current services. URApp was co-designed and iteratively optimized through extensive work with young people with incontinence to ensure it is age-appropriate and meets their needs [26].

Ethical Considerations

Ethical approval was granted by the University of Bristol Faculty of Health Science Research Ethics Committee (reference 17560) and by the Health Research Authority and Health and Care Research Wales (IRAS project ID 338625, protocol number 2023 - 7539).

Results

Participant Characteristics

From April to October 2024, 5 Children's Community Continence Service teams in England were recruited to take part (Table S1 in Multimedia Appendix 5), with participants at each site completing NoMAD questionnaires from June 2024 to January 2025. Most participants were band 6 or above (specialist) pediatric continence nurses (n=14) and had worked in a pediatric continence clinic setting for up to 5 years (n=12; Table S2 in Multimedia Appendix 5). At baseline, half of the participants (n=10) reported that they had "never used" URApp; 8 participants stated that since the study began, they "sometimes" use it with patients, and 1 had started to "routinely use" the app with patients (Table S3 in Multimedia Appendix 5). Only 3 participants responded "never use" when they completed their final NoMAD questionnaire.

NoMAD Questionnaire Data

Twelve participants completed NoMAD questionnaires at 4 time points: baseline and 6, 12, and 18 weeks (sites A-D). The remaining 7 participants (site E) completed NoMAD questionnaires at baseline and 6 and 12 weeks (Multimedia Appendix 4). Broadly speaking, sites showed collective agreement with "Coherence" NoMAD items at all time points and high levels of neutrality (score of 3, neither agree nor disagree) in relation to cognitive participation, collective action, and reflexive monitoring items. A detailed descriptive analysis of NoMAD questionnaire data, participants' free-text response data, NoMAD median scores by sites at each time point, and raw NoMAD data is provided in Multimedia Appendix 6.

XSL•FO
RenderX

Focus Group and Interview Data

Findings from NoMAD questionnaire data were expanded upon during focus group and interview discussions to gain a more in-depth understanding of why teams struggled to integrate URApp. Five focus groups were conducted with 16 participants, and 3 participants took part in one-to-one interviews. One additional participant who did not complete a NoMAD questionnaire participated in a focus group (pediatric continence nurse or nonnurse, band 5 or below), and one participant who did complete NoMAD questionnaires did not take part in a focus group or interview (specialist pediatric continence nurse, band 6 or above). Illustrative themes, corresponding NPT constructs, and quotes can be found in Table 1 and Multimedia Appendix 7.

Table . Illustrative themes, corresponding Normalization Process Theory (NPT) constructs, and quotes (N=19).

Theme (NPT construct)/subtheme	Supporting quotation
1. URApp has potential (coherence)	
Positive view of app as age appropriate	*it is nice to have something for them I would say, because with all the toileting information, well a lot of it, is based on younger children in a way, and I felt that this was something a bit more relatable to them.* (participant 4, site B-Interview[a])
Paper bladder diaries not returned	*[bladder diaries] very few and far between they get returned as well, so compliance is an issue with completing charts. That's why we thought the app would be a bit easier, because they're constantly on the phone, even parents.* (participant 7, site C)
2. It's easy to introduce… But (cognitive participation)	
Easy to introduce	*I think it's easy to talk to them about it. in terms of actually putting it out there for them to try it, that's quite a straightforward thing to do.* (participant 12, site D)
Signposting to URApp not effective	*Quite often what I find, if I signpost a young person to it, then they, you see them or talk to them again and they haven't downloaded it or haven't looked at it.* (participant 19, site E)
Asking young people to download URApp in clinic more effective	*Most of them we get them to download it in clinic. So we know they've got it.* (participant 7, site C)
3. Behavior change is hard (collective action)	
Lack of engagement from young people demotivating for staff	*I'm not seeing the massive change I thought I would see, unfortunately, I'll still be suggesting it.* (participant 15, site E)
Lack of confidence in changing from paper to electronic bladder diaries	*…other concern from parents and carers would be that actually if you've got the young person directly collecting the data how is the parent or carer going to monitor that. Whereas when they've got a paper diary invariably it goes up on the fridge, or it gets stuck up in their bedroom.* (participant 2, site A)
4. Using URApp in a school environment (reflexive monitoring)	
Impact of school culture on engagement with bladder training	*there are quite a lot of barriers to doing the good toileting and the good drinking in school*. (participant 9, site D)
Lack of toilet access	*Massive issues over toilet access in the school, and drinking. If the education sector got that on-board we probably wouldn't have a job. they could probably use their phone more than they're allowed to go to the toilet.* (participant 7, site C)
Not able to access phone at school	*Then there's been at least four that I've spoken to about it, and the person's just gone, "Oh they're not allowed their mobile phones, they're not allowed the phones in school." when they can't use it in school they're very much like no, can't use this phone, and a little bit dismissive about it.* (participant 11, site D)
More usable bladder diary data with URApp	*that [neurodivergent male] I said, you know, normally you sit here and you shrug and you don't know, you don't know. But we've got that phone now, and I've seen more data now than I ever have done. I was surprised he was doing it. So he wasn't one I thought, actually, you're going to just download it and off you're going to go because that's normally what happens. But now I bought him back sort of the, I think two months later. Yeah. and we've got some data.* (participant 6, Site B-Interview[a])

[a]Indicates interview, all other participants took part in focus groups.

Thematic Analysis With Links to Core NPT Constructs

Theme 1: URApp Has Potential (Coherence—Understanding and Opinion of the Intervention)

Although some team members were aware of URApp and other apps that could be used to support hydration and set reminders, none were actively using URApp as part of their clinical practice prior to their involvement in the study. All team members were able to download URApp onto a phone and were enthusiastic about the prospect of introducing it to patients. Teams had a positive view of app functionality (internalization) and felt that URApp had the potential to improve young people's engagement with bladder training techniques (internalization). All discussed ways in which URApp could be integrated into clinical practice to support diagnosis, by recording fluid input and output, and to aid adherence to ongoing bladder training through drink and toilet reminders and working toward a drinking goal (communal specification).

Recording data digitally in URApp differed from teams' usual practice of asking families to record fluid input/output using paper bladder diaries (differentiation). All teams reflected on the fact that tracking young people's progress using paper-based bladder diaries was not effective because families were either not completing them accurately or frequently did not return them at all (individual specification). Teams could see how URApp reminder functions were similar to their past use of basic alarms to remind young people to use the toilet and/or drink; however, all acknowledged that using a digital app with all these functions was potentially more appealing and accessible for young people and inclusive in terms of neurodiversity (individual specification). Because URApp was a new process, 2 teams acknowledged that they sometimes forgot to discuss it with eligible patients, which had hindered its integration. Team members began to discuss other ways in which URApp could be integrated into their current practice, including supporting young people with an overactive bladder and bowel issues, enabling them to record and share when relevant symptoms were occurring via the "daily diary" function (eg, damp pants and tummy ache) and by allowing young people to develop their awareness of the need to drink and use the toilet regularly, despite not being able to use URApp in school (individual specification).

Theme 2: It's Easy to Introduce… But (Cognitive Participation—Engagement With the Intervention)

All sites reported that URApp was easy to introduce because it closely aligned with the bladder training information they would routinely provide (legitimation). Nurses enjoyed introducing URApp because it was more engaging than paper-based bladder diaries, and most stated that they would continue to introduce the app in the future (activation). Nurses began by signposting families to the URApp website and asked young people to download the app in their own time at home due to limited time during clinic appointments. However, at their next clinic appointment, there were reports of young people having forgotten to download URApp. Those who were not already doing so began to ask patients to download URApp onto their phones during the clinic appointment (legitimation). This was viewed by many as a key initial step in engaging young people and ensuring they did not simply forget to download the app when they got home. Across sites, participants identified practical strategies that appeared to support the introduction and use of URApp in routine care. These strategies were subsequently refined with input from the clinical coauthors (DR and JC) to produce a set of suggested best practice recommendations (Textbox 1). In addition to introducing URApp and explaining how it could be used to support bladder training techniques, 2 sites also made changes to standard team templates, such as including the URApp website link in letters sent to parents/carers after their child's clinical appointment (site E) or developing a leaflet with the URApp link and logo (site C), to display in waiting areas for families to take away (activation). Two further sites stated that they would consider adding URApp to team templates in the future (sites A and D).

Textbox 1. Best practice when using URApp in Children's Community Continence Services.

1. Ask young person to download URApp onto their phone in their clinic appointment
2. Send URApp weblink in the clinic letter after the initial assessment so that parent/carers also have access
3. Integrate URApp into a new or existing patient care plan
4. Show young person how to record fluid intake and urine output using the "volume" function in URApp
5. Use of URApp to collect volumes of drinking and voiding and data prior to clinic visits/at intervals for 48-hour periods as an electronic bladder diary
6. Ongoing use of URApp to support bladder training—use over a weekend, during school holidays
7. Provide a National Health Service email address so that young person or parent/carer can record/email fluid intake and urine output data to the clinical team

Although one person at each site acted as a "site contact" with the URApp research team, this person had limited time to act as a "champion" for URApp in terms of integrating it more widely into team processes (initiation). At the 18-week point, site D was still "neutral" in relation to NoMAD item 5: "'there are key people who drive URApp forward and get others involved." Although, according to NoMAD questionnaires, most stated they were open to working with colleagues in new ways to use URApp, engagement with the intervention did not progress to discussions at team meetings about more structured integration of URApp into existing care pathways (enrollment). Teams felt that training and support in the form of a QR code and animation would be useful to facilitate the introduction and ongoing use of URApp. The development of an animation was

XSL•FO
RenderX

discussed as something that young people, parents, and staff might use collectively, highlighting key app functions (such as downloading data) and providing useful examples about why certain aspects of bladder training are important. Despite team members liking URApp functionality, believing that it has potential benefits for use in the community clinic setting (coherence), and enjoying introducing it to families (cognitive participation), teams reported poor uptake and lack of long-term engagement with the app from young people. This in turn impacted how teams engaged with URApp in the long term (collective action).

Theme 3: Behavior Change Is Hard (Collective Action—Putting the Intervention Into Practice)

Teams were positive about the theory and behavior change techniques that URApp was based on but found these hard to implement in practice. When nurses reengaged with young people who had been introduced to URApp but not downloaded it or had downloaded it but had not continued to use it in the long term, it was demotivating for staff who had initially thought that introducing URApp to patients would motivate young people to engage with bladder training (lack of relational integration, NoMAD item 11). Although nurses discussed more examples of feedback about URApp from female patients, they did not report any specific gender differences in relation to URApp uptake or use; therefore, this may have been due to the fact that the prevalence of daytime UI is higher among females. Some commented that URApp was appropriate for and liked by patients with neurodivergent conditions who prioritized routines or needed reminders in relation to toileting (interactional workability), while others reflected that older teenagers were not engaging with URApp. However, some highlighted that these were often patients who had been managing their condition for a long period of time and had not previously engaged with bladder training. Others felt that younger teenagers liked the rewards (eg, streaks/trophies) or were motivated by the novelty of having access to a smartphone to engage with URApp.

Although nurses discussed actively trying to encourage young people to take ownership of their bladder training, they were doubtful that young people would fully engage with data capture in URApp without monitoring and input from a parent/carer (skill set workability, NoMAD item 12). The strategy of asking young people to use URApp at their initial appointment and to remind or show their nurse how they had used it at their next clinic appointment (which could be 3 or more months later) was also not successful. One focus group highlighted that young people who volunteer to participate in co-creation research (ie, those who codeveloped URApp) may be more motivated than the patients they typically see in their day-to-day clinical practice. Parents/carers were described by all teams as leading or being actively involved in the management of their child's bladder training; particularly, in relation to recording fluid input/output using a paper-based bladder diary for 2 to 3 days prior to their child attending an initial assessment appointment. Some suggested that URApp should allow a shared parent/child login or a secondary parent/carer URApp platform to minimize these issues.

Although parents/carers played a key role in their child's engagement with bladder training, one team discussed instances where they encouraged parents/carers to step back and allow their child to take the lead, highlighting the difficulties faced by community teams balancing clinical recommendations with parent/carer preferences and young people's autonomy. Patients who were proactive and engaged with bladder training were described as making quicker progress in terms of symptom improvement, but teams also reflected on some families' broader views that medication would be more effective than bladder training. There were also reports of some follow-up appointments being conducted remotely via a speaker or video phone call without the child/young person present. Because the child/young person was not present in these instances, nurses would be unable to discuss URApp since the parent would not have access to their child's URApp data on their smartphone (lack of interactional workability, NoMAD item 9).

Despite all sites reporting low engagement from patients and their parents/carers when using paper bladder diaries to gather data, several nurses stated that they would not feel confident collecting these data using URApp, and teams did not engage with the data export function available in URApp (lack of contextual integration, NoMAD item 14). Most did not recall that URApp allows young people to measure the volume (in mL) of their fluid intake and urine output, and all reported that the URApp data export function was not used by young people (lack of skill set workability, NoMAD item 13). Currently, URApp does not automatically share bladder diary data with community clinical teams, but young people can download data and send it by email. Teams generally viewed URApp data on the young person's phone during clinic appointments. None of the teams asked young people to download or email their URApp data for review during the consultation or for inclusion in the patient's notes (lack of contextual integration, NoMAD item 14).

Although all teams reported that some young people still lacked motivation, they also acknowledged that "it takes a while for parents and children to engage" (P4B) in bladder training. Staff reflected on the timing of NoMAD questionnaires at 6 and 12 weeks, as they noted that patients' next appointment could be 3 or more months after the appointment in which they had been introduced to URApp. Therefore, nurses may not yet have reviewed a patient who was actively using URApp, potentially resulting in neutral responses to "Collective action" NoMAD items. Nurses also commented that the independent use of URApp for recording input/output over a 3-month period without clinical support would not be manageable for many young people who were typically only asked to record their fluid intake and output for a fixed period (eg, a 2 - 3 days paper-based bladder diary). Teams found the integration of URApp into existing care pathways challenging and lacked confidence in changing from paper to electronic bladder diaries. Although they were positive about young people taking ownership of their bladder condition, they were concerned about the lack of parental oversight of bladder diary data in URApp (item 11: Relational integration, item 12: Skill set workability).

XSL•FO
RenderX

Theme 4: Using URApp in a School Environment (Reflexive Monitoring—Appraisal of the Intervention)

Nurses' appraisal of URApp as an effective way of collecting data going forward was also based on reports from young people that they were unable to use URApp effectively in their school environment (a lack of effective external systematization). Patients who were engaging with URApp were largely doing so outside of school, either at weekends or because they were not currently attending school. Nurses were frustrated when patients reported restrictive school toilet policies and inadequate or unpleasant toilet facilities that did not promote healthy bladder and bowel habits or did not enable bladder training adherence. Inadequate toilet facilities resulted in young people with bladder conditions not wanting to drink fluids at regular intervals so that they did not need to use the toilet during the school day. Young people also reported significant issues with some school toilets being locked during lesson time and only accessible during breaks, when significant queues formed. There were also reports of teachers restricting access during lesson time, only allowing those with a medical or toilet pass to leave the classroom, and the use of chaperones. Young people reported that they did not want to use a medical/toilet pass to gain access to toilets during lesson time because this might highlight their condition and lead to unwanted questions from peers.

Nurses highlighted that many schools now have strict phone use policies; they either do not allow young people to use their smartphones at all during school hours or they do not allow phone use during lessons (lack of positive communal appraisal of URApp). Since toilets in some schools were only open during breaks and at lunchtime, pupils drank water less to avoid the need to use the toilet, and there were also reports of young people having limited access to drinking water during lessons (eg, not being allowed to drink water at their desks). Despite these challenges, all teams were very positive about continuing to introduce URApp to young people, and NoMAD questionnaires showed agreement from nurses on how they could modify and work with URApp in the future (item 20: reconfiguration). One team was moving toward patient-initiated follow-up and felt that URApp could potentially fit well with this new approach. Alternatives to using URApp in the school environment were suggested, such as advising young people to focus on using URApp at weekends when they have less structure in their day and struggle to remember to drink regularly and use the toilet. Individual appraisal, in terms of "valuing the effects that URApp has had on my work," was apparent when a team member had a direct experience of seeing data output from URApp when it was used effectively by patients, particularly by those who had not previously engaged with bladder training.

Discussion

Principal Findings

This is the first study to explore facilitators and barriers to embedding a digital health intervention (URApp) in Children's Community Continence Services in England. We used a mixed methods approach combining results from the NoMAD questionnaire with qualitative data from interviews/focus groups. The main findings of this study were that URApp's functionality, alignment with bladder training techniques, age appropriateness, and accessibility (eg, supporting young people with neurodivergent conditions) facilitated staff engagement with URApp. Although nurses found URApp engaging and easy to introduce, they reported broader challenges relating to young people's engagement with bladder training. School toilet access policies were reported as a key barrier to successful engagement with bladder training. Nurses did not engage with the bladder diary data export function in URApp and had concerns about relying on young people to self-manage their bladder training and digital data without access being granted to parents/carers. We found that nurses acknowledged the importance of young people taking ownership of managing their bladder symptoms; however, they also stressed their belief that successful management should be part of a shared decision-making model that includes positive support from parents/carers. Although our sample was not large enough to draw firm conclusions, our findings tentatively suggest that engagement with URApp may vary by age, with younger children appearing more responsive to app-based motivational features than older teenagers. This may reflect age-related differences in motivation and preferences but could also be influenced by changing attitudes toward smartphone use among young people, including increasing awareness of screen time and digital well-being. Policies limiting mobile phone use in schools were major barriers to engagement with URApp. These factors warrant further investigation when optimizing and implementing digital bladder training interventions.

Strengths and Limitations

This is the first study in this area to use a process evaluation approach guided by NPT; we provide valuable insights into the challenges and facilitators of embedding a digital health intervention in community pediatric continence services. Using a mixed methods approach enabled us to capture behavior change over an 18-week period and to gain an in-depth understanding of current clinical practice. Challenges included clinical teams' resistance to changing usual practice (eg, paper-based bladder diaries) and school-based barriers that prevented young people's engagement with bladder training (policies relating to toilet access and mobile phone use). Our study included Children's Community Continence Service teams in different geographical regions of England, serving rural and urban populations, but transferability of our findings is limited by the small sample size and the small number of teams involved in the study. We aimed to recruit nurses with varying levels of experience, but our sample mainly comprised nurses with up to 5 years of experience in Children's Community Continence Services. We were only able to capture behavior change in the clinical teams over a relatively short period of time (at baseline and 6, 12, and 18 wk). Constraints included the short period of funding for the study (1 y) and the length of time taken to gain capacity and capability in the 5 participating NHS sites. Data collection time points did not align well with the time period (approximately 3 months) between the initial clinic appointment, in which URApp was introduced, and routine follow-up appointments. Some team members reported that they had not yet seen patients who had previously been introduced to URApp

XSL•FO
RenderX

at a follow-up appointment. Although young people were involved throughout the development and optimization of URApp [26], patient and public involvement was not incorporated into the design, conduct, or interpretation of this process evaluation. The absence of young people and parents/carers as study participants may have limited our understanding of implementation barriers and facilitators from the perspective of end users.

Links With the Existing Literature

Empirical evidence indicates that bladder training can be effective [13,37,38]; however, the success of bladder training depends on motivation and continued engagement [39,40]. There is evidence that digital health interventions can support pediatric bladder training [26,41,42], but barriers include individuals' beliefs about the effectiveness of conservative interventions, clinicians' resistance to adopting new approaches, and environmental barriers.

Engagement With Conservative Interventions

One of our key findings was that children and young people experienced difficulties engaging with bladder training because of concerns about standing out from their peers at school and dissatisfaction with school toilet facilities. This aligns with findings from a European focus group study of children aged 9 to 13 years, which identified fear of attracting unwanted attention and dissatisfaction with school toilets as important influences on engagement with bladder training [39]. We also found that participants described frustration with symptom relapse and a lack of long-term engagement with URApp. These findings are consistent with previous UK research in which young people reported frustration with bladder training due to treatment failure and relapse, alongside disengagement from treatment following unsuccessful symptom management [9]. Participants described how school-related barriers could limit adherence to bladder training, which may contribute to perceptions among parents and young people that medication is a more practical treatment option. Similar barriers have been reported in studies of children's bladder health in school settings [43]. However, evidence from adult populations suggests that bladder training may be as effective as, or more effective than, anticholinergic medication for improving bladder symptoms [44]; therefore, further research is needed in pediatric populations.

Resistance to Adopting Digital Systems

Although health care professionals recognized the potential advantages of electronic bladder diaries, many remained reluctant to replace established paper-based approaches. This finding is consistent with implementation research showing that the adoption of digital innovations depends on staff confidence, organizational support, and the presence of local champions who facilitate new ways of working [45-47]. Evidence from mobile health research similarly highlights the important role of health care professionals in supporting engagement with digital interventions [48]. Our findings therefore suggest that implementation efforts should focus not only on patient engagement but also on enhancing health care professionals' confidence and readiness to adopt digital continence technologies.

Environmental Barriers

Although a recent systematic review reported that mobile apps for urological conditions can improve the quality of life and symptoms in adults through real-time data capture and self-monitoring [49], our findings suggest that the benefits of digital bladder training interventions may be limited by the school environment. Participants described school policies that limit access to toilets (only during morning/afternoon break or at lunchtime) and reported that toilet facilities were inadequate and unhygienic. These findings are consistent with previous research demonstrating that school environments can hinder healthy toileting and drinking behaviors [6,50-53] and are further supported by a recent systematic review, showing that restricted toilet access, poor toilet conditions, and privacy concerns represent significant barriers to healthy toileting behaviors in a school environment [54]. These findings highlight the need for greater awareness among school staff of the ongoing toileting requirements associated with bladder training, particularly in school environments where toilet access is closely regulated [55].

Participants also highlighted restricted access to mobile phones during the school day as a potential barrier to engagement with URApp. This challenge may become increasingly important as schools adopt stricter policies regarding phone use [56,57]. Although smartphone ownership among young people is high [58], more than half of children aged 8 to 17 years are not permitted to use their phones during school hours [59]. While UK guidance emphasizes schools' responsibilities to support pupils with medical conditions, including access to drinking water and toilet breaks when needed, it does not address the use of digital health tools to support self-management [55,57]. Given growing evidence that mobile health interventions can improve adherence and self-management across a range of health conditions [60], further research is needed to determine how school phone policies can support equitable access to digital health interventions for young people with medical conditions.

Implications for Policy, Practice, and Future Research

The successful implementation of digital bladder training interventions requires action at multiple levels. Within Children's Community Continence Services, efforts should focus on increasing NHS staff confidence in digital tools and integrating electronic bladder diary data into routine practice. Although health care professionals recognized the potential value of URApp, reluctance to replace established paper-based approaches suggests that staff training, organizational support, and local implementation champions may be important for successful adoption [45,61]. Our findings also highlight the importance of involving young people, parents/carers, and health care professionals in shared decision-making. Previous research found that young people wished to take ownership of their continence management and viewed smartphone apps as a supportive tool for self-management [26]. Future research should explore how shared decision-making influences engagement with digital interventions and adherence to bladder training.

XSL•FO
RenderX

Beyond health care settings, participants in this study consistently identified the school environment as a major barrier to bladder training adherence. Schools should be supported to develop policies that balance educational priorities with pupils' needs for regular toilet access and hydration [6,52,54]. In addition, schools should consider how digital health technologies can be accommodated for pupils who rely on them to manage long-term health conditions [55,57]. As schools increasingly adopt restrictions on mobile phone use, alternative implementation strategies may be required, including negotiating health-related exemptions, permitting their use during school holidays, or delaying data entry outside school hours. More broadly, our findings highlight the importance of considering organizational, educational, and policy contexts when implementing digital continence interventions.

Conclusions

Using URApp in community clinics has the potential to align pediatric continence care with the NHS 10-year health plan [62] by focusing on early intervention in a community setting and using digital technology to capture and store data. URApp is free to download, available for both iOS and Android phones, and has the potential to empower young people to self-manage their symptoms between clinic appointments. Digitizing bladder diaries may lead to improved treatment outcomes, improved patient experience, and reduced barriers to accessing health care. Future implementation of URApp into existing clinical care pathways will need to consider how electronic bladder diary data from URApp can be used more effectively by clinical teams, in partnership with patients and their parents/carers.

Abstract

Background: AI is increasingly being integrated into education and health care, offering opportunities to improve learning, understanding of clinical cases, and students' self-confidence. However, it remains necessary to assess nursing students' perceptions of AI and its impact on their academic and professional development.

Objective: The aim of the study was to assess AI use among nursing students, their perceptions of AI, and its impact on learning, academic performance, and professional preparation.

Methods: A descriptive cross-sectional study with analytical components was conducted at the Faculty of Medical Technical Sciences in Elbasan, Albania. Data were collected through a structured questionnaire administered via Google Forms, which assessed AI use and its perceived impact on learning and professional preparation. Data were analyzed using SPSS (version 23.0). Descriptive statistics, chi-square tests for associations between variables (P<.05), and logistic regression to estimate crude odds ratios (CORs) and adjusted odds ratios (AORs) with 95% CIs were used.

Results: A total of 279 nursing students participated in the study (mean age 22.4, SD 5.7 years), the majority of whom were female (273/279, 97.8%), lived in urban areas (156/279, 55.9%), and were enrolled in the bachelor's program (198/279, 71%). Overall, 83.9% (234/279) reported using AI, mainly virtual assistants such as ChatGPT or similar tools (183/234, 78.2%). The most common reason was information searching (216/234, 92.3%), followed by studying and understanding lecture content (96/234, 41%). Bivariate analysis showed no significant associations between AI use and residence or study cycle, whereas grade point average (GPA) was significantly associated with AI use. In the multivariable analysis, GPA remained the only independent predictor of AI use. Students with a GPA of 6.0 to 6.9 (AOR 5.55, 95% CI 1.53-20.14; P=.009) and those with a GPA of 8.0 to 8.9 (AOR 5.73, 95% CI 1.26-26.00; P=.02) were significantly more likely to use AI than the reference group. Students perceived AI as having a moderate impact on learning, particularly understanding lectures (mean 2.58, SD 1.10) and exam preparation (mean 2.58, SD 1.02), whereas its impact on self-confidence (mean 1.97, SD 1.17) and empathy (mean 1.90, SD 1.12) was perceived as low. Although AI was considered useful for supporting learning (mean 2.83, SD 1.12), students expressed concerns regarding the reliability of AI-generated information (mean 3.18, SD 1.22), dependence on AI (mean 2.75, SD 1.28), and its impact on critical thinking (mean 2.80, SD 1.18).

Conclusions: AI is widely used among nursing students, primarily supporting learning and academic performance. However, its impact on professional and interpersonal competencies remains limited. These findings suggest the need for integrating AI into nursing education curricula, with a focus on critical use and the development of students' professional competencies.

Introduction

In the last decade, AI has been one of the most important developments in the field of technology, and it has been integrated into various fields, including health care [1-3]. Its use is changing not only the way health care services are delivered but also the way future health care professionals are prepared, especially in the context of decision-making and patient management [4].

AI is also having a visible impact on nursing education. Today, students no longer rely solely on traditional learning methods but increasingly use digital methods to understand and assimilate their theoretical and practical knowledge [5]. AI-based technologies such as virtual simulations, virtual patients, and intelligent systems supporting decision-making have enabled an interactive and safe environment for the development of critical thinking and clinical reasoning [6,7]. These tools also contribute to the development of nursing care plans and an improved understanding of complex clinical processes [8].

Recently, a special role has also been played by various generative AI platforms such as ChatGPT and similar tools, which have become part of students' daily lives [9]. These tools offer quick access to information, help explain difficult concepts, support the processing of academic materials, and generate structured responses similar to those produced by humans [10-12]. For nursing students, these technologies provide potential support for academic performance and professional development by linking theoretical, practical, and clinical knowledge [13].

Various studies have shown that the use of AI improves clinical reasoning abilities, critical thinking, and self-confidence in practice [1,14]. AI also provides personalized and interactive information, adapting to students' needs and offering rapid feedback [15,16]. At the same time, the use of technology can help improve the quality of patient care through continuous support in monitoring and decision-making [17].

However, beyond its benefits, the literature shows that the use of AI is associated with a series of challenges and concerns in the field of nursing education. Uncontrolled use of AI may lead to reduced active student involvement in the learning process, increased dependence on technology, and reduced professional competence [18-20]. Other concerns relate to the accuracy of information, academic privacy, and the risk of plagiarism [21,22], issues that are particularly sensitive in the field of nursing.

Another aspect that should not be neglected is the need to develop new competencies among nursing students, including the critical use of technology and data analysis [23]. Importantly, AI cannot replace the human elements of the nursing profession such as empathy, communication, and patient care [24].

Although the use and impact of AI in nursing education continue to grow, evidence on how students use and perceive it in practice remains limited. Most studies focus on evaluating the theoretical benefits of AI, while less attention has been paid to students' real-life experiences and the factors influencing their use of AI in the educational context [11]. Moreover, there are several barriers such as the lack of standardization in AI education and inequalities in access [25].

It is important to study nursing students' perceptions and experiences regarding the use of AI tools, with a focus on identifying benefits, challenges, and implications to develop educational policies for the most effective and ethical use of AI [26,27].

Therefore, the aim of this study was to assess the use of AI among nursing students, their perceptions of AI, and the perceived impact of AI tools on the learning process, academic performance, and professional preparation.

Methods

Ethical Considerations

The study was not submitted for formal ethics review because it was conducted through an anonymous, voluntary, minimal-risk web-based survey and did not involve the collection of personally identifiable or sensitive personal information. Electronic informed consent was obtained from all participants before accessing the questionnaire. Participants were informed about the purpose of the study, voluntary participation, confidentiality, and anonymity. No personally identifiable information was collected, and participants could withdraw at any time by choosing not to complete the survey. All data were collected, stored, and analyzed anonymously in accordance with the general principles of research integrity outlined in the institutional framework [28], and no compensation was provided.

Study Design and Setting

A descriptive cross-sectional study with analytical components was conducted among students enrolled in the General Nursing program at the Faculty of Medical Technical Sciences, University of Elbasan, Albania. The study was carried out between January 2026 and March 2026.

Study Population and Sampling

The study included all students enrolled in the bachelor's and master's General Nursing programs. Students from other study programs and other universities were excluded. Participants were selected using convenience sampling, and participation was voluntary. The minimum sample size was calculated using the Cochran formula with a 95% CI, a 5% margin of error, and a total population of 1020 students. The calculation resulted in a minimum required sample size of 279 participants.

Data Collection Procedure

Data were collected using a structured, self-administered questionnaire developed by the authors and distributed online through Google Forms (Alphabet Inc) in student communication groups. Participants were informed about the purpose of the study and were assured of the confidentiality and anonymity of their responses. Before completing the questionnaire, all participants provided electronic informed consent. Only fully completed questionnaires were included in the final analysis. Due to the method of questionnaire distribution, the exact

XSL•FO
RenderX

number of students who received the survey link could not be determined.

Study Instrument

The study instrument was developed by the authors based on the scientific literature regarding the use of AI in nursing education. The questionnaire was developed in Albanian and consisted of 3 sections.

The first section included demographic and academic information, including age, sex, place of residence (urban or rural), study cycle (bachelor's or master's), and academic grade point average (GPA). In the Albanian grading system, grades range from 4 to 10, with 10 representing the highest academic achievement. For analytical purposes, GPA was categorized into 5 groups: <6.0, 6.0 to 6.9, 7.0 to 7.9, 8.0 to 8.9, and 9.0 to 10.0. This section also included questions regarding AI use, frequency of use, types of AI tools used, and purposes of use. Questions related to AI tool types and purposes of use allowed multiple responses. AI tools were categorized as virtual assistants (ChatGPT [OpenAI], DeepSeek [DeepSeek AI], and Copilot [Microsoft Corp]), educational platforms (Learning Nurse; Steppingstones Partnership Inc), text-generation and text-enhancement tools (paraphrase tool), and other tools used for academic support and information retrieval. AI use was initially assessed using a screening question (yes or no). Only participants who reported using AI proceeded to the subsequent questionnaire sections, which assessed frequency of use, types of AI tools used, and the perceived impact of AI on learning and professional preparation. Participants who reported not using AI completed only the demographic and academic sections.

The second section assessed the perceived impact of AI on learning and professional preparation. This section included questions on AI's impact on understanding lectures, exam preparation, academic performance, time saving during studying, understanding clinical cases, nursing care, self-confidence during clinical practice, critical thinking, communication skills, and empathy toward patients. All questions were assessed using a 5-point Likert scale ranging from 1 ("no influence") to 5 ("very high influence"). For statistical analysis, these variables were grouped into 2 main dimensions: academic impact and professional impact.

The final section assessed students' perceptions regarding the use of AI in nursing education. It included statements about the usefulness of AI, its impact on learning quality, the risk of dependence on technology, the reliability of AI-generated information, and its potential impact on critical thinking. Responses were recorded using a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree").

Validity and Reliability

To evaluate the clarity, comprehensibility, and relevance of the questionnaire items in relation to the study objectives, the questionnaire was reviewed by 4 academic staff members with expertise in nursing education and research methodology. Their suggestions were considered, and minor modifications were made to the wording of several questions. Subsequently, a pilot test was conducted with 20 nursing students who had characteristics similar to those of the study population to assess comprehensibility, feasibility, and the time required to complete the questionnaire. On the basis of participants' feedback, minor revisions were made to improve the instrument. Data collected during the pilot study were not included in the final analysis.

The internal consistency of the questionnaire was evaluated using the Cronbach α coefficient. The scale assessing the perceived impact of AI on learning outcomes (10 items) demonstrated excellent reliability (α=0.937). The scale assessing perceptions of AI use (6 items) demonstrated good reliability (α=0.810). These findings indicate satisfactory internal consistency for both scales, supporting their suitability for further statistical analyses.

Data Analysis

Data were analyzed using SPSS (version 23.0; IBM Corp). Statistical analysis was conducted in several steps. First, descriptive statistics were used to summarize students' sociodemographic and academic characteristics, as well as variables related to AI use. Categorical variables were presented as frequencies and percentages, whereas continuous variables were described using means and SDs. Variables measured using Likert scales were also analyzed descriptively and presented as frequencies and percentages for each response category, as well as means and SDs for each item.

The chi-square test was used to assess associations between AI use and categorical variables. Factors associated with AI use were further analyzed using logistic regression. Both crude odds ratios (CORs) and adjusted odds ratios (AORs), together with 95% CIs, were reported. A *P* value <.05 was considered statistically significant.

Results

General Characteristics

A total of 279 students enrolled in the General Nursing program participated in the study. Of these, 273 (97.8%) were female and 6 (2.2%) were male. The mean age of the participants was 22.4 (SD 5.7) years. More than half of the students (n=156, 55.9%) lived in urban areas, while 123 (44.1%) resided in rural areas. The majority of participants (n=198, 71%) were enrolled in the bachelor's program. Regarding academic performance, 123 (44.1%) students had a GPA of 7.0 to 7.9, followed by 78 (28%) with a GPA of 6.0 to 6.9. Additionally, 45 (16.1%) students reported a GPA of 8.0 to 8.9 and 12 (4.3%) had a high GPA of 9.0 to 10.0. Students with a GPA of <6.0 accounted for 7.5% (n=21) of the participants. Overall, 234 (83.9%) students reported using AI tools (Table 1).

Use of AI

A high proportion of students (234/279, 83.9%) reported using AI. Among the 234 AI users, 105 (44.9%) reported daily use, while 69 (29.5%) used AI on a weekly basis. Less frequent use was reported by a smaller proportion of participants, with 20.5% (n=48) using AI rarely and 5.1% (n=12) using it once a month. Regarding the types of AI tools used, 183 (78.2%) participants reported using virtual assistants such as ChatGPT, DeepSeek, or Copilot. Educational platforms such as Learning Nurse were used by 63 (26.9%) students, while text-generation tools were reported by 36 (15.4%) participants. In addition, 21.8% (n=51) of participants reported using other AI tools. Regarding the purpose of AI use, the majority of students (n=216, 92.3%) used AI for information searching. Additionally, 41% (n=96) of participants used AI for studying and understanding lecture content, 16.7% (n=39) for academic assignments, and 12% (n=28) for understanding clinical cases (Table 2).

Factors Associated With the Use of AI

Bivariate logistic regression analysis showed that place of residence and study cycle were not significantly associated with the use of AI. Although students living in urban areas had higher odds of using AI than those living in rural areas, this association was not statistically significant (COR 1.56, 95% CI 0.82-2.96; *P*=.23). Similarly, no statistically significant difference was observed between bachelor's and master's students (COR 0.84, 95% CI 0.42-1.65; *P*=.74).

In contrast, academic performance (GPA) was significantly associated with AI use. Compared with students with a GPA <6.0, those with GPAs of 6.0 to 6.9, 7.0 to 7.9, and 8.0 to 8.9 had higher odds of using AI, whereas no statistically significant association was observed for students with a GPA of 9.0 to 10.0.

In the multivariable analysis, place of residence and study cycle remained statistically nonsignificant. After adjusting for the variables included in the model, GPA remained the only independent factor associated with AI use. Students with a GPA of 6.0 to 6.9 (AOR 5.55, 95% CI 1.53-20.14; *P*=.009) and those with a GPA of 8.0 to 8.9 (AOR 5.73, 95% CI 1.26-26.00; *P*=.02) were approximately 5 times more likely to use AI than the reference group (GPA<6.0). The association observed for the GPA category of 7.0 to 7.9 in the bivariate analysis was no longer statistically significant after adjustment (AOR 1.69, 95% CI 0.59-4.85; *P*=.33), suggesting a possible influence of confounding factors. Similarly, no statistically significant association was found between AI use and the GPA category of 9.0 to 10.0 (AOR 0.51, 95% CI 0.11-2.33; *P*=.38; Table 3).

Students' Perceptions of the Impact of AI

Participants generally reported a low to moderate impact of AI on learning outcomes, with mean scores ranging from 1.90 to 2.95 on a 5-point Likert scale. The highest perceived impact was reported for understanding clinical cases (mean 2.95, SD 1.20), followed by exam preparation (mean 2.58, SD 1.02) and understanding lectures (mean 2.58, SD 1.10), suggesting that AI plays a primarily supportive role in cognitive and academic processes. AI was also perceived as helpful in saving time during studying (mean 2.49, SD 1.22).

The perceived impact was lower in psychosocial and professional dimensions, including academic performance, critical thinking, communication skills, and nursing care. The lowest mean scores were reported for empathy toward patients (mean 1.90, SD 1.12) and self-confidence (mean 1.97, SD 1.17; Table 4).

Table . Impact of AI on learning outcomes (n=234).

Items	1: no influence, n (%)	2: low influence, n (%)	3: moderate influence, n (%)	4: high influence, n (%)	5: very high influence, n (%)	Scores, mean (SD)[a]
Understanding lectures	52 (22.2)	49 (20.9)	84 (35.9)	43 (18.4)	6 (2.6)	2.58 (1.10)
Exam preparation	45 (19.2)	54 (23.1)	93 (39.7)	39 (16.7)	3 (1.3)	2.58 (1.02)
Academic performance	81 (34.6)	54 (23.1)	81 (34.6)	15 (6.4)	3 (1.3)	2.17 (1.02)
Time saving while studying	60 (25.6)	66 (28.2)	60 (25.6)	30 (12.8)	18 (7.7)	2.49 (1.22)
Understanding clinical cases	36 (15.4)	39 (16.7)	87 (37.2)	45 (19.2)	27 (11.5)	2.95 (1.20)
Nursing care	87 (37.2)	39 (16.7)	78 (33.3)	21 (9)	9 (3.8)	2.26 (1.16)
Self-confidence	117 (50)	42 (18)	48 (20.5)	18 (7.7)	9 (3.8)	1.97 (1.17)
Critical thinking	84 (35.9)	57 (24.4)	69 (29.5)	15 (6.4)	9 (3.8)	2.18 (1.10)
Communication skills	99 (42.3)	39 (16.7)	60 (25.6)	24 (10.3)	12 (5.1)	2.19 (1.23)
Empathy toward patients	126 (53.8)	33 (14.1)	54 (23.1)	15 (6.4)	6 (2.6)	1.90 (1.12)

Students' Perceptions of AI Use

Students' perceptions of the use of AI were generally characterized by a moderate level, with mean scores ranging from 2.45 to 3.18 on a 5-point Likert scale. The highest level of agreement was reported for concerns regarding the reliability of AI-generated information (mean 3.18, SD 1.22), reflecting a considerable degree of skepticism about its accuracy.

Overall, AI was perceived as a supportive tool for the learning process (mean 2.83, SD 1.12) and for improving the quality of studying (mean 2.77, SD 1.14), suggesting a generally neutral to slightly positive perception of its use in education. However, moderate concerns were also expressed regarding its impact on critical thinking (mean 2.80, SD 1.18) and the risk of developing a dependence on AI (mean 2.75, SD 1.28; Table 5).

Table . Students' perceptions of AI use (n=234).

Statements	1: strongly disagree, n (%)	2: disagree, n (%)	3: neutral, n (%)	4: agree, n (%)	5: strongly agree, n (%)	Scores, mean (SD)[a]
AI is a useful tool.	39 (16.7)	35 (15)	102 (43.6)	40 (17.1)	18 (7.7)	2.83 (1.12)
AI improves the quality of learning.	39 (16.7)	45 (19.2)	84 (35.9)	51 (21.8)	15 (6.4)	2.77 (1.14)
AI helps in preparation for professional practice.	54 (23.1)	75 (32.1)	78 (33.3)	15 (6.4)	12 (5.1)	2.45 (1.08)
AI negatively affects critical thinking.	39 (16.7)	61 (26.1)	72 (30.8)	39 (16.7)	23 (9.8)	2.80 (1.18)
AI may create dependency.	66 (28.2)	27 (11.5)	75 (32.1)	42 (17.9)	24 (10.3)	2.75 (1.28)
Information from AI is not always reliable.	33 (14.1)	6 (2.6)	84 (35.9)	60 (25.6)	51 (21.8)	3.18 (1.22)

[a]Higher scores indicate stronger agreement with the statement.

Discussion

Principal Findings

This study identified a high level of AI use among nursing students, with 83.9% (234/279) reporting that they used AI tools. This finding is consistent with previous studies reporting the widespread use of digital technologies in higher education [29]. However, daily use was reported by only a proportion of students, suggesting that AI is used primarily as a functional tool for specific academic tasks and information retrieval rather than as a continuously integrated component of the learning process [30].

The results showed that the most commonly used AI tools were virtual assistants, particularly ChatGPT and similar applications (78.2%), reflecting a global trend toward the use of AI as a learning support tool. This finding is consistent with the existing literature, which suggests that AI facilitates access to information and supports the understanding of complex academic concepts [31-34]. However, the fact that AI was used mainly for information searching rather than for developing clinical skills or critical thinking suggests that students perceive AI primarily as an informational resource rather than an educational tool [9].

Overall, students perceived the impact of AI on both academic and professional outcomes as low to moderate. The greatest perceived impact was reported for understanding clinical cases and preparing for examinations, whereas the lowest perceived impact was reported for empathy toward patients, self-confidence, communication skills, and critical thinking. These findings suggest that AI is primarily perceived as a supportive tool for accessing and organizing information, while its role in developing interpersonal and professional competencies remains limited.

The greater perceived impact on understanding clinical cases may be attributed to the ability of AI tools to provide structured explanations, practical examples, and simplified clinical information. Similarly, the moderate perceived impact on understanding lectures and preparing for examinations suggests that students use AI as a complementary learning resource rather than as a transformative factor in academic performance [11,35,36].

Conversely, the limited perceived impact on critical thinking may reflect students' uncertainty regarding the role of AI in developing analytical reasoning and reflective skills. Likewise, the low perceived impact on empathy and self-confidence suggests that students do not consider AI to be an important contributor to their professional development. These findings support the view that although AI can facilitate the learning process, it cannot replace the human dimensions of nursing practice, such as empathy, communication, and the nurse-patient relationship [37,38].

A considerable proportion of students also expressed concerns regarding the reliability of AI-generated information, the risk of dependence on AI, and its potential impact on critical thinking. These perceptions suggest that uncontrolled AI use may limit the development of clinical judgment and encourage reliance on ready-made answers without sufficient critical reflection [18,27].

XSL•FO
RenderX

At the same time, students reported positive perceptions regarding the benefits of AI in improving learning efficiency and facilitating access to information. This finding reflects a balance between the perceived benefits and risks of AI, with acceptance of the technology accompanied by awareness of its limitations [39-41]. These results suggest that nursing education is currently in a transitional phase of AI adoption, in which students recognize its potential while remaining cautious about its academic and professional implications.

Logistic regression analysis showed that academic performance (GPA) was the only independent factor associated with AI use. Students with GPAs ranging from 6.0 to 8.9 were more likely to use AI than those with lower GPAs. These findings suggest that students with better academic performance are more likely to integrate digital tools into their learning strategies, consistent with previous studies reporting a positive association between academic achievement and technology use in education [33,42].

However, the absence of a statistically significant association among students with the highest GPA (9.0-10.0) suggests that this relationship may not be linear. One possible explanation is that high-achieving students may be more selective and critical in their use of AI, preferring traditional learning methods. It should also be noted that the small number of participants in this subgroup may have reduced the statistical power of the analysis.

In contrast, place of residence was not significantly associated with AI use, suggesting relatively equal access to digital technologies among students from urban and rural areas. Similarly, no association was found between AI use and study cycle, indicating that AI use was comparable among both bachelor's and master's students. These findings suggest that AI use in this context is influenced more by individual factors, such as exposure to technology and personal attitudes toward innovation, than by the level of academic study [29,43].

Overall, the findings of this study indicate that AI is already widely integrated into the learning process of nursing students; however, its use remains primarily supportive and informational. Although students recognize its benefits for accessing and organizing information, important limitations remain regarding its use for developing clinical and professional competencies. These findings highlight the need for a more structured integration of AI into nursing curricula through educational approaches such as simulation-based learning, virtual clinical cases, and supervised AI-assisted learning activities, with the aim of strengthening students' critical thinking, clinical reasoning, and professional competencies.

Study Limitations

This study has several limitations. First, as the data were based on self-reported responses, the findings may be subject to reporting bias and subjectivity in students' perceptions and evaluations of the impact of AI. Furthermore, the use of an online questionnaire may have favored participation by students who were more familiar with or interested in technology. In addition, the cross-sectional design and the conduct of the study at a single institution did not allow for the assessment of causal relationships, thereby limiting the generalizability of the findings. Therefore, future studies should use more comprehensive research approaches, including qualitative methods such as interviews, to gain a deeper understanding of nursing students' perceptions and experiences regarding the use of AI. Moreover, multicenter studies with larger and more diverse samples are recommended to improve the representativeness and generalizability of the findings.

Conclusions

The findings of this study showed that nursing students had a generally positive attitude toward the use of AI and perceived it as a supportive tool in the learning process. However, its impact was greater on theoretical aspects, whereas its impact on their professional and interpersonal skills was more limited. These results emphasize the need for a more advanced integration of AI into nursing education. Training, experience, the development of digital competencies, and a supportive academic environment are essential for these tools to be used effectively.

Acknowledgments

The authors thank all nursing students from the Faculty of Medical Technical Sciences in Elbasan who participated voluntarily in this study and contributed to the data collection.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Abstract

Background: Pressure injuries (PIs) are a common complication in people with reduced mobility or sensation and can be burdensome for individuals with PIs and their caregivers. Valuable insights and real-world challenges faced by individuals living with PIs can be captured through candid accounts posted on social media. Social media listening (SML) is a tool that can enhance the understanding of those with lived experience by offering firsthand accounts that are irreproducible from controlled studies.

Objective: This study aims to capture the candid experiences of individuals with PIs and caregivers through social media.

Methods: A noninterventional qualitative descriptive analysis was conducted using SML. Social media posts made on X (formerly Twitter), Reddit, and YouTube between January and December 2022 were compiled using SML tools X Pro (formerly TweetDeck) and Awario, and using Boolean search terms. Posts were manually screened for relevance, and duplicates were removed. Relevant posts were hand-coded by two independent reviewers. Inductive content analysis was used to analyze the posts.

Results: The search yielded 666 relevant posts from 498 unique social media users. Most posts were made in the United States (170/666, 25.5%), the United Kingdom (150/666, 22.5%), and Canada (62/666, 9.3%). Social media users provided detailed descriptions of the PIs, including the setting in which the PI occurred, the cause of the PI, and how the PI was managed. The majority of PIs (197/666, 29.6%) were reported to have occurred in the hospital setting due to a perceived lack of care from care providers, and local wound care was often cited (99/666, 14.9%) as a PI management strategy. Three key themes were developed regarding living with or caring for someone with a PI: (1) challenges experienced when living with or caring for a PI, (2) needs related to PI prevention and management, and (3) emotions experienced when living with or caring for a PI. Social media users frequently discussed challenges associated with living with a PI, including negative personal impacts and poor perceived treatment quality. Users also described a critical need for health care, education, and social support. Finally, users often expressed anger and/or sadness related to living with or caring for a PI.

Conclusions: SML captured candid insights into the experiences, challenges, and needs of individuals living with PIs and their caregivers globally that may not be gleaned from controlled studies. Individuals with lived experience and their caregivers often struggled with negative personal impacts regarding their physical health and daily functioning related to PIs, further highlighting the urgent need to address barriers to appropriate PI care. Clinicians and policymakers should consider practices and policies that optimize the delivery of person-centered PI care in order to overcome challenges and needs identified in this study.

(JMIR Nursing 2026;9:e76682) doi:10.2196/76682

KEYWORDS

social media listening; social media; pressure injury; pressure ulcer; bedsore; caregiver

Introduction

Pressure injuries (PIs) occur due to damage to the integrity of the skin and underlying soft tissue resulting from severe and persistent localized pressure and shear, usually over a bony prominence [1-3]. Those at risk of developing PIs include older individuals and individuals with reduced mobility or sensation [1,3]. The global prevalence rate of PIs has remained stagnant at around 12% over the past few decades [4,5], which is notable because most PIs are avoidable if appropriate prevention techniques are applied [6]. This prevalence is especially troubling since PIs impose severe physical, mental, social, and

XSL•FO
RenderX

emotional impacts on those living with or caring for them [7-11]. Individuals living with PIs often experience physical discomfort, social isolation, and challenges when performing daily activities [8]. Similarly, caregivers of individuals with PIs may experience a high caregiving burden and a low quality of life [12,13]. PIs also cause tremendous financial strain on affected individuals and the US health care system, with an estimated yearly expenditure of US $26.8 billion on hospital-acquired PIs [14].

The burdens and challenges of living with a PI may go unrecognized or unaddressed by the health care teams caring for individuals with PIs [8,11]. Patient-centered care, which incorporates patients' and caregivers' perspectives, preferences, needs, and goals, is essential for addressing patients' challenges and improving treatment adherence and patient outcomes [15,16]. An interventional study of hospitalized patients admitted for acute medical or surgical treatment comparing usual care with patient-centered interventions revealed that a patient-centered educational intervention resulted in greater confidence in medication adherence [17]. Similarly, an interventional study conducted in an inpatient ward specializing in care for patients with neurological, orthopedic, or musculoskeletal conditions revealed that the active involvement of patients and their colleagues during nursing clinical handovers resulted in a decrease in hospital-acquired complications [18]. Thus, understanding the perspectives of individuals living with PIs and their caregivers may provide insights into improving the delivery of patient-centered PI care [15,16].

Over the past few decades, social media has become a vital resource where communities of individuals living with health conditions and their caregivers from around the world share unfiltered opinions, seek health information, and connect with one another [19]. Social media platforms such as YouTube, X (formerly Twitter), and Reddit are popular forums for individuals to seek social support and health information or share their personal experiences with their health conditions and subsequent treatment [20]. The increasing use of social media by patient and caregiver communities presents a valuable opportunity for researchers to elucidate candid patient and caregiver perspectives and experiences as reported on social media sites [19]. This is made possible through social media listening (SML) [21,22], a research method that involves performing a systematic search of public social media platforms. SML uses tools such as Talkwalker, Salesforce Social Studio [23,24], and X Pro (formerly TweetDeck) to identify real-world, firsthand accounts of individuals' experiences with disease and treatment, quality of life, and unmet needs [23,25].

SML can be used as a complementary research method alongside traditional qualitative or quantitative studies and has been shown to yield several benefits [19]. Given that patient recruitment is not required, SML can reduce recall and reporting biases that may be present in interviews or retrospective data collection methods by removing the researcher from the discussion [19]. SML also allows researchers to collect data from patients without geographic restrictions, providing large-scale insight into a topic [19]. SML has been shown to be an effective method of understanding patient and caregiver perspectives, unmet medical needs, and adherence to treatment that may not have been previously identified in the literature [23-28]. For instance, Perić et al [23] explored the needs and lived experiences of patients with graft-versus-host disease by using Talkwalker to search for relevant posts on Twitter, Facebook, Instagram, and YouTube. Similarly, Kline et al [24] used Salesforce Social Studio and Talkwalker to understand unmet needs, barriers to treatment, patient journey, and treatment options for patients living with amblyopia. Other similar studies have investigated individuals' experiences with various medical conditions, providing critical insights into individuals' quality of life, treatment, and perception of their quality of care [27-30].

While previous studies have explored the challenges faced by individuals living with PIs and caregivers who provide support [8,11,13,31], their perceptions of their role in PI care [9,16,32], as well as their knowledge, information needs, and preferences for PI education [15,33-35], none have used an SML approach to explore their experiences. Given the benefits of SML and the pervasive use of social media in the present day, SML may provide important, unique, and unfiltered insights into the experiences, challenges, and needs of individuals with PIs and caregivers globally that may not be elucidated from traditional studies. Thus, our study aimed to capture the experiences, challenges, and needs of individuals with PIs and caregivers using SML, an emerging research method that could reveal aspects of the PI experience not easily observed in controlled research environments.

Methods

Study Design

This study implemented a noninterventional qualitative descriptive approach to analyze publicly available social media posts made on X (formerly Twitter), Reddit, and YouTube using SML software Awario and X Pro. The study design was conceived by postgraduate students and scientists with extensive experience in both qualitative and quantitative research. We used the SRQR (Standards for Reporting Qualitative Research) guideline [36] to draft this manuscript and the SRQR reporting checklist [37] when editing (Checklist 1).

Search Strategy

Overview

Between May and June 2023, comprehensive searches were conducted on Reddit and YouTube using Awario. Searches were simultaneously conducted on X using X Pro. Awario and X Pro enable users to search web-based platforms for phrases and keywords in public posts in a similar manner to a literature search [38,39]. Both Awario and X Pro identified English-language posts made between January 1 and December 31, 2022. X, Reddit, and YouTube were selected as popular open-access social media websites where users commonly share personal opinions and experiences, enabling us to feature the perspectives of a wide range of individuals. Predefined Boolean search strings were used to identify relevant posts on each social media platform, and Boolean operators (AND/OR) were used to combine each keyword within the strings (Multimedia Appendix 1). The search string included key terms related to pressure injury and alternate words for pressure injury, such as

XSL•FO
RenderX

"bedsore" and "pressure ulcer," as well as care recipients' or caregivers' identities (ie, grandparents, parents, sister).

Definitions

A "user" or "social media user" referred to individuals with lived experience (ie, individuals who had experience living with a PI), caregivers (ie, individuals who provided direct, unpaid care to someone with a PI), or observers (ie, individuals who were not explicitly a caregiver but had witnessed someone else's PI experience as their friend or relative) who posted content on social media. Observers were distinguished from caregivers by their level of participation in providing PI care: caregivers explicitly provided care for someone with a PI, whereas an observer did not provide direct care for an individual with a PI but appeared to be actively involved in the life of an individual with a PI (eg, friend, colleague, or family member). A "post" was defined as any social media content identified through the search. A "mention" was defined as a reference to a specific topic within posts, which was used for coding in the analysis.

Inclusion and Exclusion Criteria

Social media posts from X, Reddit, and YouTube were included for analysis if they were written or recorded in English by individuals with lived PI experience, caregivers, or observers. In order to be included in the study, the social media post had to contain content relating to personal experiences with PIs (ie, experiences of living with a PI, caring for someone with a PI, or observations of another person's experience with PIs). There were no restrictions in terms of the user's geographic location.

Posts were excluded if they mentioned the development of a PI from medical masks or if the user did not fit the definition of an individual with lived PI experience, caregiver, or observer. Posts were also excluded if the user was a paid caregiver or health care professional (HCP) and if the post contained product endorsements or advertisements.

Data Screening

The results of each Boolean search were entered into a Microsoft Excel spreadsheet. Each X, Reddit, and verbatim transcript of the YouTube post was manually reviewed for relevance based on the inclusion and exclusion criteria before being input into a separate spreadsheet for content analysis. Any posts that did not meet the inclusion criteria or the exclusion criteria (eg, product endorsements) were removed. Duplicate posts that contained identical text were identified using the sort function of the spreadsheet and removed manually by researchers. To ensure interplatform data consistency, we applied common inclusion and exclusion criteria across platforms. Screening and verbatim transcription were performed in duplicate by two independent researchers to enhance trustworthiness.

Data Collection: Post Characteristics

Users' relationships with individuals living with a PI, geographic location, and intended audience were documented whenever such information was available from the users' social media profiles or could be inferred from the posts. Otherwise, users were classified as "unknown." Post details including the posting date, retrieval date, source platform (ie, X, Reddit, or YouTube), post format (ie, video, forum post, or tweet), and post hyperlinks were also documented on a Microsoft Excel spreadsheet.

Summative Content Analysis

Overview

Segments of text within each social media post were assigned a label (ie, code). Given that multiple segments of text within each social media post may have been present, social media posts were often assigned more than one code. Summative content analysis was used [40,41] through inductive coding; theme generation; and code, subcode, and theme frequency measurement.

Theme Generation

Inductive coding was used to formulate a comprehensive codebook. Primary codes, corresponding subcodes, example posts for reference, and code definitions were determined through an iterative process. The initial creation of codes and subcodes was performed independently by four research team members (PM, Pilar Tabuenca [PT], Uchechukwu Akunna [UA], and SG) based on post content, and the final codebook was developed following an exhaustive discussion by the team and the refinement of initial codes and subcodes. Disagreements were resolved through a discussion between coders or by an additional coder, if needed. Codes and subcodes were assigned to the relevant posts on a Microsoft Excel spreadsheet. Emotion codes were assigned to each post based on Plutchik's emotion wheel [42], which identifies eight primary emotion codes—joy, trust, fear, surprise, sadness, disgust, anger, and anticipation—along with their combinations. To ensure the reliability of the coding, these code assignments were later double-checked by four independent researchers (AI, AAO, IT, and JZS) and input into NVivo 12 (QSR International), a qualitative data management software.

The codes and subcodes were then consolidated into major themes representing the experiences of individuals with lived PI experience as reported on social media following further discussion by the research team. Posts were double coded under the same theme when they reflected multiple aspects of the theme; for instance, posts often described both personal impacts and perceived quality of treatment that were encountered while caring for a PI, which both fell under the theme of "Challenges experienced when living with or caring for a PI." As a result, the number of mentions (ie, codes) per theme surpassed the number of total posts in some cases.

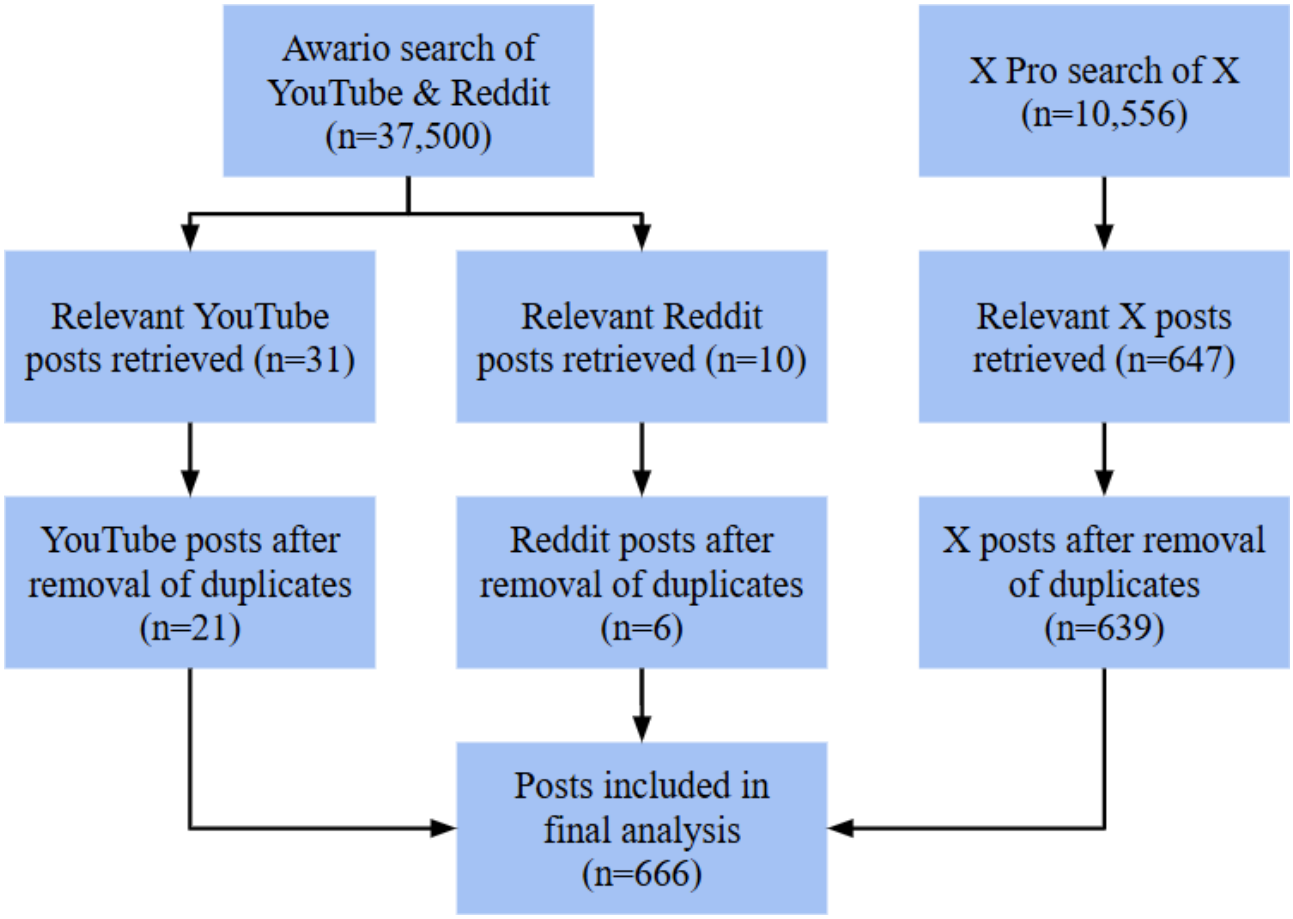
Frequency Measurement

Code, subcode, and theme frequencies were calculated using NVivo 12. Frequency was similarly calculated and summarized for users' demographic information (ie, geographic location, intended audience, and relationship to the individual living with a PI).

Ethical Considerations

This study was exempt from human subject research ethics review because all data were obtained from public, internet-based sources, as per University Health Network [43] and University of Toronto [44] policies. No human participants were directly involved in this study, and as such, compensation

XSL•FO
RenderX



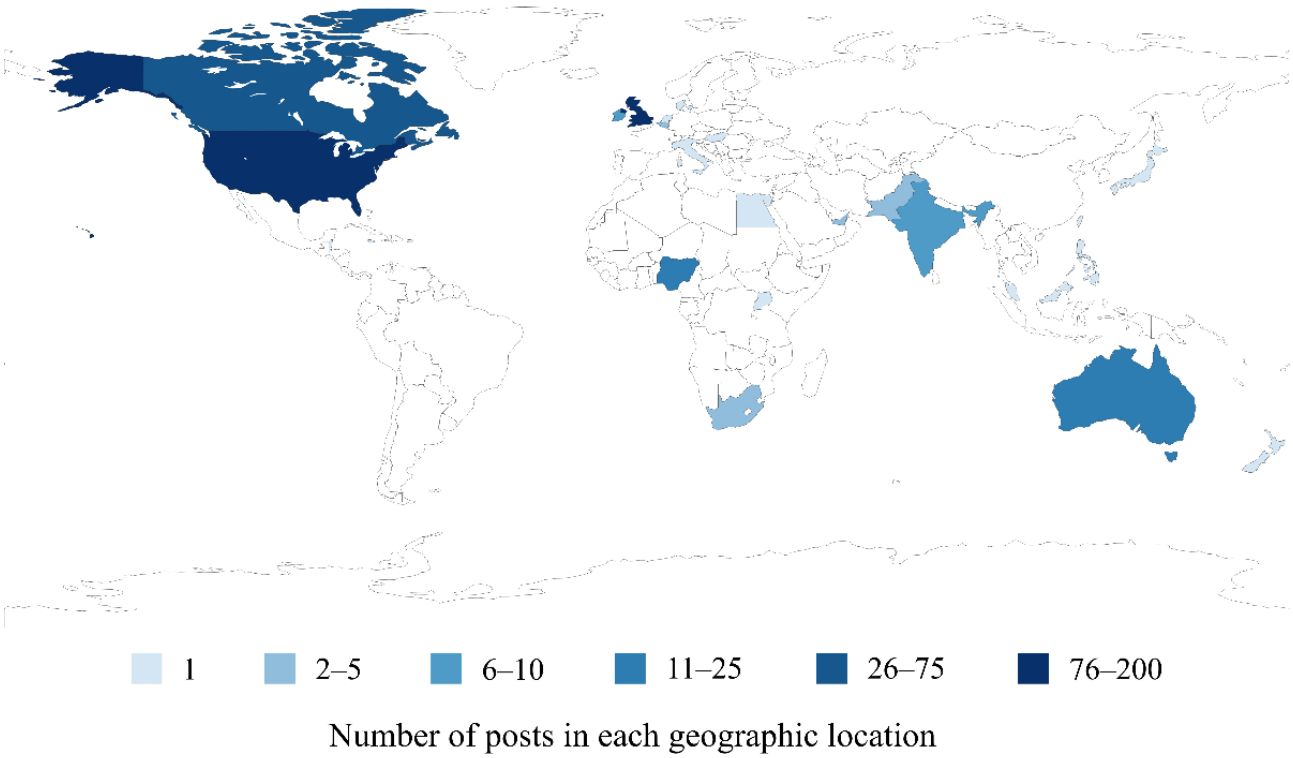
was not provided. Study data were deidentified, and any identifiable information was removed from the study analysis, manuscript, figures, and tables.

Results

Search Strategy and Data Screening

The initial search retrieved 37,500 and 10,556 posts from Awario and X Pro, respectively (Figure 1). After three independent researchers (PM, PT, UA) manually screened the posts, 41 relevant posts were identified from Awario, and 647 relevant posts were identified from X Pro. Duplicate posts were then removed. Ultimately, 639 X posts, 6 Reddit posts, and 21 YouTube videos were identified as relevant to the study objectives.

Figure 1. Flow diagram depicting the process of selecting relevant English-language social media posts made between January 1 and December 31, 2022, using social media listening (SML) software programs Awario and X Pro.



Post Characteristics

Our study identified 498 unique social media users across X, YouTube, and Reddit who generated a total of 666 posts. Of the 666 posts, 361 (54.2%) were posted by observers, 219 (32.9%) were posted by caregivers, and 86 (12.9%) were posted by individuals with lived PI experience. Caregivers and observers were often the child or other relative (eg, grandchild, sibling, parent) of the person with a PI. Most posts (n=631, 94.7%) were intended for the general public, although a few were targeted at specific health care institutions or other individuals (ie, governments, support groups). Most posts (n=481, 72.2%) were intended to share information about PIs with others (eg, warnings, knowledge about PI progression, causes, and complications), while some posts were intended to blame or advocate for others. Posts most frequently originated from the United States (n=170, 25.5%), the United Kingdom (n=150, 22.5%), or Canada (n=62, 9.3%), as seen in Figure 2.

Figure 2. Heat map displaying the distribution of social media posts according to geographic location.

Overview: The Pressure Injury Experience

Table 1 displays characteristics related to the PI experience, including the description of the PI, risk factors and causes of PIs, PI symptoms, the setting where the PI occurred, PI management, and commentary about PI healing. In posts (n=666), users frequently discussed the severity of the PI (n=120, 18%) and the location of the PI on the body (n=116, 17.4%). Several users described comorbidities (eg, dementia, obesity) as a risk factor for developing a PI (n=105, 15.8%), and many users cited a lack of care from HCPs or caregivers as the direct cause of their PI (n=156, 23.4%). Additionally, pain and discomfort were commonly reported symptoms (n=56, 8.4%). Many PIs were reported to have been hospital-acquired (n=197, 29.6%), and the most commonly reported PI management strategy was local wound care (n=99, 14.9%; eg, debridement, cleaning). A few users described the healing process of their PI (n=41, 6.2%).

Pressure injury description		
Severity	120	"… my back, bottom & legs were a mass of pressure sores, two so severe that you could fit a large man's fist into the holes."
Location on body	116	"My Mum had a bedsore at the bottom of her spine right through to the spine. It killed her …"
Size	50	"… she had heel pressure ulcers the size of a silver dollar and deep ..."
Appearance	36	"… her bottom became an un-stageable bedsore. After surgery to remove [the] blackened and dead flesh, you could actually see her lower spine."
Number	34	"I'm alive, but I am dealing with three separate pressure ulcers …"
Duration	33	"Almost seven years of dealing with that pressure sore and it's finally healed …"
Risk factors of pressure injury		
Comorbidities	105	"She keeps getting UTIs and now she has a pressure sore that's slow to heal. She needs a hoist to get up. Her dementia is getting worse ..."
Immobility	50	"… She was essentially immobile, and fat. It took three hospital staff every time she needed to be repositioned to prevent bedsores."
COVID	15	"My mom got COVID… A few months later, she got an infection from a bedsore, got sepsis, and passed away. I believe COVID weakened her immune system …"
Body mass	15	"[He] was about 1200 pounds, bedridden, and ended up having a huge wound as a result of a bedsore."
Thin skin	7	"My mom went in hospital and got pressure ulcers like that within days ... Her skin was very thin."
Cause of pressure injury		
Lack of care	156	"She has two pressure sores on one foot as the carers in the home didn't move her when she was out of it for a couple of days."
Immobility	103	"... [My grandpa was] completely paralyzed. Ended up dying from a bedsore because of it."
Comorbidities	63	"…due to my spin a (sic) bifida and lack of sensation in some areas of my body I developed pressure ulcers on my sacrum and was hospitalized for wound care and sepsis."
Equipment-related	39	"I got a pressure sore on the back of my heel from my cast …"
Symptoms related to pressure injury		
Pain or discomfort	56	"My gran was constantly crying due to pressure ulcers …"
Bleeding or exudate	12	"… We are bringing my dad to see someone about some bedsores we are worried about because they're starting to bleed."
Odor	3	"… I could smell the infection as soon as I entered the room."

Setting where pressure injury occurred		
Hospital (ie, ICU[b], ER[c])	197	"... I've seen how they treated my mother in the hospitals ... She came home with a bedsore."
Care home	64	"Just like my loved one in LTC a couple of years back … She was yelling and crying out and the staff dismissed it as a regular dementia behavior … She ended up with a terrible pressure sore …"
Home	63	"Got my first pretty bad pressure sore since coming home, I do not want to go back to the spinal unit man."
Pressure injury prevention and management strategies		
Local wound care	99	"... [My dad] had surgery to debride bedsores."
Use of equipment (eg, cushion, mattress)	38	"... [My mom] had a scary bedsore & was given a gel pad for chair & bed. I have a gel mattress which is great for not getting bedsores …"
Offloading	21	"... You are the person who turns her over every 2 hours or she will get bedsores."
Bed rest	14	"[He] has been trying to heal a pressure sore by being on bed rest for nearly a year."
Inspection or assessment	14	"… I do skin checks every morning when I get up, every evening when I go to bed, and every time I go to the bathroom, I check the vulnerable areas."
Medication	14	"Just beginning my 3rd month in hospital as a result of a pressure sore. 9 weeks of IV antibiotics due to osteomyelitis."
Nutrition	11	"When I was recovering from severe damage related to my pneumonia/sepsis episode (stage 3 pressure ulcers, crushed immune system, etc.) they made me aim for 120 [grams of protein] every day. Three medical Ensures, special feeding tube formula ..."
Healing of pressure injury		
Healing process	41	"At the start the pressure sore needed 3 packing strings. Now, only half of 1 fits in."
Healing time	25	"My grandma (86) got a really bad bedsore … After nearly 20 months, it's finally almost healed."
Lack of healing	22	"I have a pressure sore right now that's been open for several months and not close to healing …"
Worsening	12	"My downfall was a pressure sore which rapidly went from bad to worse …"

[a]Some posts contained multiple constructs of the PI experience.

[b]ICU: intensive care unit.

[c]ER: emergency room.

Theme 1: Challenges Experienced When Living With or Caring for a Pressure Injury

Within the 666 posts, there were 807 mentions related to the challenges associated with living with a PI, caring for someone with a PI, or receiving care for a PI. A total of 423 out of 807 (52.4%) mentions identified the personal impact or impacts of living with a PI or caring for someone with a PI, with 221 out of 423 (52.2%) mentions discussing the challenges associated with PI complications, such as infection and death. A total of 158 out of 423 (37.4%) mentions related to the personal impact of living with a PI reported a negative impact of PI or caregiving on overall functioning (eg, work or employment, mobility, daily activities) and perceived quality of life. A total of 23 out of 423 (5.4%) mentions related to the personal impact of living with a PI reported negative financial impacts (ie, struggling to afford

XSL•FO
RenderX

treatment), and 21 out of 423 (5%) discussed negative mental health impacts such as depression and social isolation.

> *My dad died from overwhelming sepsis due to osteomyelitis caused by his bedsores [and] of course everyone in the ICU had [pneumonia]. I checked his chart each day [and] it was sad to see signs of life slowly slipping away. Pressors couldn't keep him up.*
>
> *Mum has to stay in bed most of the day cause of pressure sore/open wound, we only transfer her to chair for a few hours.*

Additionally, there were 241 out of 807 (29.9%) mentions of the perceived quality of PI treatment received, with 205 out of 241 (85.1%) mentions describing poor care practices such as lack of care and misdiagnosis from HCPs that commonly led to PI complications for the individual. A total of 36 out of 241 (14.9%) mentions related to the perceived quality of treatment reported witnessing poor attitudes of caregivers and HCPs when treating the individual with a PI.

> *I had no idea [my mom] was suffering from a level 4 bedsore [because] the facility didn't tell me. The hospital told me. Shameful. This is the norm in most LTC facilities. This has to change. Now. #nursinghomeneglect.*
>
> *I haven't even mentioned some of the worst parts of this. My mom developed multiple new pressure ulcers at [healthcare facility]. I've had nurses and therapists privately tell me how bad things are at [healthcare facility]. I was told a nurse practitioner sighed in disappointment that my mom was improving.*

Furthermore, there were 102 out of 807 (12.6%) mentions related to perceived health care system issues when accessing services to treat PIs. Of these 102 mentions, 57 (55.9%) reported issues with accessing equipment or services (eg, difficulties obtaining pressure mattresses, long hospital wait times) and 26 (25.5%) mentions described prolonged hospitalization or inability to be discharged due to these challenges with health care access. Additionally, 19 out of 102 (18.6%) mentions related to perceived health care system issues described witnessing critical staffing shortages at health care facilities that contributed to the deterioration of the individual with lived PI experience.

> *Please help. Nobody will give us an air mattress for my elderly sick bed bound father! It's a disgrace when he is starting to get bedsores. He's under palliative care but without complex needs!!!!*
>
> *My poor dad ended up with a giant bedsore while on the barely staffed dementia ward at a [location] care home. He died of sepsis because of it. I was always stunned that there never seemed to be anyone up there working! So effed up!*

Finally, there were 41 out of 807 (5.1%) mentions related to a perceived lack of knowledge from HCPs, caregivers, or individuals with lived PI experience. Of these 41 mentions, 22 (53.7%) described a perceived lack of HCP's PI knowledge that contributed to the development or worsening of a PI. Moreover, 19 out of 41 (46.3%) mentions related to a lack of knowledge indicated the individual with lived PI experience or caregivers' lack of knowledge related to PIs or their prevention and management.

> *My mother had a horrendous [suppurating] bedsore on the back of her head after 8 weeks solid lying prone. We didn't know what it was but asked a nurse who shrugged and said, "Oh, that's weird. I don't know what it is" and walked off. It took 18 months to heal once home.*
>
> *I can't wait to look at my birthday messages, but [right now] I'm going to see my grandma [because] she's going to the hospital [for] bedsores that we don't know how to take care of.*

Theme 2: Needs Related to Pressure Injury Prevention and Management

There were 110 mentions about the users' needs related to PI prevention and management. Of these 110 mentions, 39 (35.5%) described a need for health care support. These mentions shared the users' need to receive PI care from HCPs, as well as the difficulty in accessing care.

> *[I have] infected pressure ulcers. Can't get ahold (sic) of family doctor. Virtual care clinics are booked up for multiple days—no way to get myself to a clinic.*
>
> *No, I had been trying to get treatment for pressure sores, but both my family members had covid at the time and couldn't take me to any appointments due to being covid positive.*

Moreover, of the mentions related to the user's needs related to PI prevention and management, 38 out of 110 (34.5%) mentions were related to a need for educational support. These mentions described users' need for advice from HCPs, health care organizations, or the general public related to PI prevention or management.

> *My dad is in a care home. He has dementia and now bad grade bedsores. Doctor said they are bad and could turn sepsis and [there is] nothing else they can do. Do I need a second opinion? Please help. Thanks.*
>
> *[My dad's] bedsores are bad which the Doctor has said could lead to sepsis. Any help or advice, please.*

In addition, there were 26 out of 110 (23.6%) mentions related to the need for social support. These mentions often described a need for spiritual guidance, prayers, or words of encouragement.

> *Please pray for me, I'm suffering with a pressure sore that won't go away.*
>
> *I've been dealing with a pressure sore for a [little] bit now. Today I found out it's infected. It's very triggering as pressure sores is how I lost my legs. Please send good vibes [or] distractions and stuff. I feel awful.*

Finally, there were 7 out of 110 (6.4%) mentions related to users' need for financial support. In these mentions, users requested assistance with medical bills related to PI prevention or management.

XSL•FO
RenderX

[Please] help my family to pay my mom's hospital bill. There's another 16 [days] left for surgery but yesterday my mom got admitted due to sudden bedsores and she's in pain right now. We [do not have any] income to buy the medication.

Please help me. I'm getting pressure ulcers from having to lay in bed a lot due to feeling unwell from my cancer. I started a [GoFundMe] a while ago and it hasn't got too much traction. I love you all and hope you'll take a second to boost this.

Theme 3: Emotions Experienced Related to Living With or Caring for a Pressure Injury

There were 478 mentions related to emotions when experiencing a PI, including primary emotions (ie, joy, trust, fear, surprise, sadness, disgust, anger, and anticipation) and a combination of these primary emotions (eg, anger and sadness, fear, and anger). Of the 478 mentions related to emotions experienced, negative emotions were frequently mentioned: 91 (19%) of the emotions included anger, 36 (7.5%) included sadness, and 68 (14.2%) included a combination of the two. Combinations of sadness with other primary emotions (eg, disgust, surprise, anticipation) were also frequently observed in 82 (17.2%) of the mentions. In total, 62 (13%) of the mentions included a combination of anger with other emotions. Combinations of fear with other emotions were also common in 54 (11.3%) of the mentions.

My mother is in aged care. Now transferring to palliative care after neglect. Massive bedsores despite instructions from doctor on how to position her. $600k plus daily fees for neglect and malnutrition that will ultimately see her out. We are beyond furious.

I am a mess, honestly. My sister and I take turns everyday feeding and hydrating her. She has a nasty bedsore, bone exposed … We can't even get her up to take her for a walk. I am just sad.

I've been TERRIFIED of getting pressure sores for a decade [and] half now, given my super low ability to move even in the bed I'm stuck in. I'm sitting or lying almost 24/7 … I'm super high risk [and] when it finally happens ... The [doctors] don't care.

Positive emotions were less frequently mentioned and included joy in 11 out of 478 (2.3%) mentions, anticipation in 5 out of 478 (1%) mentions, or both in 21 out of 478 (4.4%) mentions. Often, these emotions were expressed when describing appreciation for the kindness of others or anticipation related to the PI recovery process or prognosis.

My heart bleeds seeing my dad this way, bedsore has taken over but your donations kept him till this time. I can't thank you all enough but I know my God will reward you for your good deeds amen.

Today's goal: I'm hoping to take him on a wheelchair expedition outside his room--maybe even the hospital--for the first time in 2 months! Hopefully his pressure ulcer and spinal pain will allow it.

A good day! Nurse says pressure sore looking good, don't need to bandage it up with padding anymore. I should be able to pick up drugs at Tesco later [and] I think I can try get driving assessed and car adapted so I can drive with foot drop while it's healing! STOKED!!! #traumarehab

Discussion

Overview

To our knowledge, this is the first study investigating the experiences and perspectives of individuals with lived PI experience as shared through public social media posts. Using SML, we were able to capture the candid experiences and perspectives of individuals with PIs and caregivers that may not be easily gathered from controlled studies. Based on our findings, three major themes were developed: challenges experienced when living with or caring for a PI, needs related to PI prevention and management, and emotions experienced when living with or caring for a PI.

Principal Findings

Perceived Challenges of Living With or Caring for a PI

The most frequently mentioned perceived challenge related to PIs was the personal impact of living with a PI or caring for someone with a PI; most mentions involved challenges associated with complications of PIs, such as infection and death. Previous work notes that individuals living with PIs have an estimated two times higher risk of mortality compared with individuals living without PIs, often due to the development of severe infections [45]. Individuals with PIs are at high risk for bacteremia, which can cause a mortality of over 50% [46]. The findings from this work may help guide the development of strategies to help address this concern among those with lived PI experience.

Social media users frequently mentioned the negative impacts of PI on the daily, physical, occupational, or general functioning of individuals living with PIs. Previous studies on caregivers and those living with PIs identified similar experiences, with individuals reporting a reduction in mobility, independent movement, and quality of life [47-49]. A recent systematic review found that individuals living with PIs often demonstrated declines in physical function and activity, along with low quality of life scores [50]. These deficits are exacerbated by PI complications, such as pain and odor, which may impede the performance of physical and social activities [50]. In alignment with best practices for PI prevention and management, a holistic interprofessional approach should be used to address not only the PI but also the complications of living with a PI to help optimize outcomes.

Perceived poor quality of treatment related to PI management by HCPs or caregivers was reported by social media users. Posts often mentioned poor attitudes of HCPs and caregivers and neglect of the individual with lived PI experience, leading to increased pain experienced by the individual with lived experience, the development or worsening of a PI, infection, and even death. Other studies have highlighted negative attitudes of HCPs toward PI prevention and/or management as well as HCPs who engage in inadequate PI care practices [51-55]. These deficits in practice are potentially related to reported low levels of knowledge of HCPs related to PI prevention and management

XSL•FO
RenderX

[56-60]. This sentiment was shared by social media users in this study who reported a lack of HCP knowledge related to PI management.

According to the knowledge, attitudes, and practices model, knowledge may correlate with attitudes and health practices [61,62]. Thus, the reported lack of knowledge among HCPs may have also contributed to the reported negative attitudes and suboptimal care practices reported by social media users in this study. This is supported by previous studies investigating nurses' attitudes and perceived barriers toward PI prevention and management, which found that inadequate nurse training and knowledge were major obstacles contributing to their negative attitudes and inadequate practices [7,63,64]. Since low knowledge about PI may lead HCPs to adopt poor attitudes and health care practices, the need to ensure that HCPs receive sufficient training in PI prevention and management should be considered.

In addition to a lack of training and knowledge, HCPs have cited a lack of time and equipment (ie, pressure-relieving devices) as prominent perceived barriers to care delivery [51,65-67]. Other studies have found that staffing shortages and inadequate HCP training were persistent barriers to PI prevention practices [68-71]. These findings align with results from the present study, as social media users commonly identified health care system issues, including staffing shortages and lack of availability of equipment (eg, specialized mattresses). Health care system–related barriers appear to be shared globally, and future initiatives should ensure that equipment for PI prevention and management is accessible in order to optimize health outcomes for individuals living with PIs.

PI-Related Needs Among Those With Lived Experience

HCPs play a pivotal role in ensuring that the health care needs and goals of the person living with the PI are met [72,73]. Therefore, it is not surprising that the most frequently mentioned need identified by social media users was health care support related to managing PIs. Although best practice guidelines include self-management where people living with PIs assume responsibility for their PI [74], the frequent sentiment of social media users was the need for health care support, highlighting the limitations of self-management alone. Additionally, users often reported a continued need for HCP support, suggesting the need for ongoing provision of services. One potential contributor to the prevalent need for support may be the inaccessibility of PI resources. Previous studies have demonstrated that individuals seeking specialized medical care experience barriers related to long wait times and high treatment costs, making it exceptionally challenging to obtain relevant services [75,76]. Thus, these barriers may impact individuals' access to satisfactory PI care, driving their self-reported need for health care support.

Social media platforms provide a resource for individuals seeking guidance on managing their illnesses, allowing them to benefit from the advice and experiences shared by others [77,78]. As such, our study found that one of the most commonly expressed needs of individuals living with PIs was their request for advice and information regarding PIs. Social media can be beneficial as an educational resource because authentic accounts of an individual's illness can make medical information more relevant to the user's situation and help them to better understand it [78]. However, given the large volume of information available on the internet, the quality of information can vary widely [79] depending on its source and other post characteristics (eg, length of the post, author credentials). A study evaluating the quality of health information shared on online discussion forum websites, such as Reddit, found that posts shared by medical doctors were "of reasonably good quality" [80]. A recent study by Bang et al [81] that examined the quality of PI health information on YouTube found that longer videos produced by a physician and other health personnel contained more accurate and reliable information about PI prevention and management. In contrast, health information on X may not be reliable: a recent retrospective cohort study revealed that X users were approximately 974 times more likely to encounter inaccurate than accurate information about monkeypox [82]. Similarly, another study found that while authenticated authors on X with large followings were more likely to produce accurate posts about COVID-19, over 25% of the posts were inaccurate, indicating that this information may not be reliable for educational purposes [83]. Future studies should evaluate the quality of PI health information on various social media platforms and elucidate the factors impacting information quality to provide guidance for users regarding where and how to obtain reliable and accurate information.

Social media serves not only for sharing individual experiences but also for offering and receiving support [78]. In our study, social support emerged as a frequently mentioned need, which aligns with previous study findings that many caregivers of adults with cancer expressed a desire for social support in the form of prayers and patient visitation [84]. Individuals living with PIs are particularly vulnerable to social isolation due to the challenges associated with immobility and body image issues due to characteristics of PIs such as exudate and malodor [7,85]. Hence, social media may be a valuable resource for those living with PIs, allowing them to connect with others who can offer support. This notion is further supported by a study on social media use among adults during the COVID-19 pandemic, which highlighted how social media platforms can be major sources of social support amid isolation, ultimately aiding in the reduction of loneliness [86]. Future work should consider developing interventions to address the social isolation that individuals living with PIs may face.

Emotions Experienced as a Result of a Pressure Injury

In this study, anger, sadness, and a combination of the two emotions were the most frequently cited among social media users. This aligns with previous research findings that individuals with lived PI experience and caregivers often feel negative emotions such as anger, frustration, and sadness due to the lengthy healing process of PIs, lack of care received, and PI symptoms such as pain [7,32,50,87-89]. In the qualitative study of Latimer et al. [32] that explored the perceptions of individuals with PIs regarding their role in PI prevention, participants reported feeling angry and frustrated about failing to receive appropriate PI preventative care and experiencing

XSL•FO
RenderX

negative interactions with HCPs. These findings suggest that the PI experience is often distressing and can incite intense negative emotions in those living with or caring for a PI. However, it is important to note that social media users tend to engage with and share negative emotions and experiences (eg, anger and distress) more frequently than positive ones on these platforms [90-95]. In addition, studies have shown that those in the online health community may be more likely to post negative content to seek emotional and informational support [96,97]. The platform X in particular has been associated with messages displaying highly negative emotions [92]. Given that X was our primary source of data, the potential likelihood of predominantly negative experiences reported on X was high, and as a result, our findings may be skewed. Nonetheless, our findings provide valuable insights into individuals' experiences living with or caring for a PI, highlighting the negative emotional impact of the pervasive challenges associated with preventing and managing PIs.

Implications for Digital Health

Our study identified the candid experiences, challenges, and needs of individuals with PIs and their caregivers, which have several actionable implications for digital health. In this study, individuals living with PIs and their caregivers frequently expressed a need for information and advice regarding PIs and PI care. Additionally, social media users often reported a continued need for HCP support throughout the PI journey, which they lacked access to. These findings suggest that researchers and clinicians should prioritize the development of accessible online PI educational materials or platforms for individuals with PI and caregivers. Online PI resources or platforms (eg, websites, mobile health apps, social media pages) could provide contact information for HCPs or health organizations, enabling individuals with PI and/or their caregivers to access PI information or support when needed. Disseminating critical health information in a centralized and accessible forum may help promote health literacy among individuals with PIs and caregivers who rely on social media sources to supplement knowledge gaps. In addition, given the widespread use of social media today, it may also be useful to develop social media campaigns to educate the general public about PIs to combat general misinformation.

SML allowed us to identify patterns in the experiences and struggles of individuals with PI and their caregivers, such as a perceived lack of adequate PI care received and lack of knowledge among HCPs. These issues may subsequently be targeted and addressed by relevant regulatory or health entities to improve patient experiences and outcomes. As such, we note that SML may be used in the future to complement digital health surveillance technology, as researchers may utilize SML to observe and track ongoing trends in the reported challenges and needs of individuals with PI and caregivers on social media. The information gathered by SML can generate important longitudinal insights into whether prevailing issues are being adequately addressed and what critical areas of health care improvement health care organizations and policymakers should focus on.

Limitations

While our study is strengthened by a rigorous screening and coding process to analyze and interpret social media data, we acknowledge several limitations. First, since researchers hand-coded all social media posts, it is possible that some codes were missed due to human error affecting the accuracy of the reported frequencies. However, this process was carried out through a meticulous process (ie, researchers held iterative discussions to determine codes and code definitions, with coding performed in duplicate), so this is not a notable concern. Additionally, we broadened search terms in our Boolean search strings to widen our search and maximize the number of relevant posts. However, we acknowledge that some of these search strings could be streamlined and improved upon in the future for optimal retrieval and efficiency in our analysis. Furthermore, only English-language posts were included, which largely limited our search results to content from English-speaking countries. Moreover, most of the posts included were created by users in the United States, meaning our findings may predominantly reflect the health care experiences of individuals living in this country. Another potential limitation is that we only searched YouTube, Reddit, and X; a broader range of social media platforms may have yielded more posts for inclusion. Additionally, we found that X yielded a disproportionately large number of posts compared with YouTube and Reddit, which may have skewed our analysis toward findings from X. Also, the format of posts across the selected platforms was very different and thus difficult to collectively analyze. As such, future research using SML may benefit from selecting more comparable social media platforms to facilitate analysis or analyzing posts from each platform separately. Additionally, we were unable to obtain a complete demographic profile of social media users (eg, age, gender, or sex) due to the limited demographic information available on social media user accounts. Since we analyzed posts from observers, caregivers, and individuals with lived experience as a homogeneous group, differences between the experiences, challenges, or needs of each subgroup were not elucidated. Future studies may benefit from subgroup analysis to identify unique findings for caregivers and individuals with lived experience. Finally, we acknowledge that there may be sampling bias present in our study, as social media users are often younger and more technologically literate [98]. Also, while we did not restrict our sample in terms of geographic location, we acknowledge that there are inequities in technology access and thus ability to use social media platforms [99]. These limitations may reduce the generalizability of our findings.

Conclusions

Our study used SML to explore the unfiltered experiences shared by individuals affected by PIs (ie, individuals with lived PI experience, caregivers, and observers) across social media platforms X, YouTube, and Reddit. We found that many users described challenges associated with PIs and PI care related to the negative personal impacts of living with a PI and receiving inadequate care from HCPs, highlighting the need to address these issues and identify barriers to appropriate PI care. Additionally, social media was often used to request or express a need for health care support and education, suggesting a

XSL•FO
RenderX

critical need for supportive and educational resources for those affected by PIs. Finally, the most frequently observed emotion across posts was anger, consistent with previous findings that individuals with lived PI experience and caregivers often experience negative emotions about the PI experience. Our findings provide valuable insights into the candid experiences of individuals living with PIs, uncovering several gaps in care and research that require intervention to improve the well-being of these individuals. Clinicians, policymakers, and researchers should prioritize addressing the prominent challenges and needs identified from this work to optimize PI care delivery and patient outcomes.

Acknowledgments

We would like to acknowledge Pilar Tabuenca and Uchechukwu Akunna for their help with coding of the data. Generative artificial intelligence was not used in the analysis or writing of the manuscript.

Funding

This study was funded by the University Health Network Foundation. The funders had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Abstract

Background: The growing aging population and staff shortages are placing pressure on Dutch nursing homes (NHs). These challenges have led to an increased interest in digital health technologies. Among these are wearable devices that allow for remote continuous monitoring of vital signs. An example is the Healthdot (smartQare), a wearable electronic device that continuously monitors heart rate, respiratory rate, and physical activity. In the context of acute respiratory infections (ARIs) in NHs, where initial symptoms can go unnoticed, continuous monitoring may aid in early recognition, timely intervention, and reduce staff workloads. However, little is known about how health care professionals perceive the use of continuous vital signs monitoring devices, such as the Healthdot, for this cause in NHs.

Objective: This study aims to explore the perspectives of healthcare professionals on the use of the Healthdot for early detection and monitoring of ARIs in NHs, to inform potential future implementation.

Methods: Semistructured interviews were conducted with 20 physicians, nurses, and certified nursing assistants from 4 NHs and 1 acute geriatric community hospital located in a NH. Interview transcripts were thematically analyzed to identify themes regarding their perspectives on the use of the Healthdot for monitoring ARIs in this setting.

Results: Five main themes were identified that related to the appropriate use of the Healthdot for NH clients and health care professionals: alignment of Healthdot use and NH clients' treatment policies, balancing safety and freedom, impact of the Healthdot on work processes, supporting rather than replacing care, and possible use during pandemics and in the future. Additionally, several preconditions for the use of the Healthdot were identified, including its usability, a support base among care staff, adequate training and guidance, communication with NH clients and their relatives, and a clear policy regarding its use.

Conclusions: Given the complexity of care in NHs, where clinical care is typically balanced against quality of life and a homelike environment, physicians generally expressed reserved attitudes toward the Healthdot, highlighting the need to consider multiple factors in its implementation. Care staff were generally positive about the device. Nevertheless, tailored assessment for each individual NH client remains essential, balancing treatment goals, safety, autonomy, and person-centered care. Additionally, clear communication and alignment between health care professionals in this setting are crucial, specifically regarding their expectations of the Healthdot's role in care processes. This study offers practical guidance that may inform future implementation efforts of continuous vital sign monitoring devices in NHs.

Introduction

Nations across the globe are experiencing a demographic shift toward an older population [1]. The growth in aging populations, combined with a shortage of health care professionals [1,2], is placing a significant burden on Dutch nursing homes (NHs) [3]. In light of these challenges, digital health technologies, such as surveillance or vital signs monitoring devices, are increasingly being explored as promising tools to support care delivery in NH settings [4,5]. According to the Dutch central government, providing care digitally can not only provide older adults with more autonomy but can also support health care professionals by relieving their workload [6]. Implementing these technologies in NHs cannot only help address the issue of staff shortages but also has the potential to improve the quality of care [4,6,7].

One recurring health care problem frequently encountered in NHs involves acute respiratory infections (ARIs) [8]. Early recognition of ARIs and associated clinical deterioration in frail older adults remains challenging, as initial symptoms may go unnoticed, and NH clients with cognitive impairment often struggle to communicate their symptoms, leading to diagnostic and treatment delays [8,9]. Measurement of objective parameters possibly associated with ARIs, such as temperature, heart rate, respiratory rate, oxygen saturation, and reduced physical activity, could potentially be helpful for early recognition of ARIs and associated clinical deterioration [10]. One promising digital health device for remote vital signs monitoring is the Healthdot (smartQare), a wearable electronic patch that measures heart rate, respiratory rate, and physical activity (scored from 0 to 15, ranging from lying still to intensive movement such as sports) [11]. In the future, this application may be used by health care professionals in NHs to support them in making appropriate care choices regarding suspected ARIs, which can be focused on treatment and comfort. Additionally, automated monitoring of heart rate and respiratory rate by the Healthdot may reduce the workload for NH staff by obviating the need for these manual measurements.

While these prospects seem promising, little is known about how health care professionals in NHs perceive the use of wearable devices for continuous vital signs monitoring of ARIs. Insight into their views is essential to facilitate and inform potential future implementation and may help overcome both known and unknown challenges. This qualitative interview study, therefore, explores the perspectives of health care professionals on the use of the Healthdot for monitoring ARIs in NHs.

Methods

This interview study is part of the research project PRIMA (Plaster-Based Respiratory Infection Monitoring Assistant), which focuses on validating the Healthdot for recognizing clinical deterioration in NH clients with ARIs [12]. We used a qualitative research approach to gain a rich understanding of the perspectives of health care professionals on this topic. This study adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines (Checklist 1) [13].

Recruitment and Study Population

Four NHs and 1 acute geriatric community hospital (AGCH) located in a NH were invited to participate in this interview study. These organizations were previously approached during the recruitment phase of the PRIMA project, in which only one of the NHs and the AGCH participated. Hereafter, the term “NH client” refers to both NH residents and AGCH patients located in a NH. In this interview study, all 5 organizations agreed to participate and invited health care professionals within their organizations to take part in the interviews. The invitation was broadly distributed by email, explicitly requesting representation from different professional groups, including physicians, nurses, and certified nursing assistants. A contact person from each organization provided the researchers with the contact details of health care professionals who were interested in participation.

Participants were included if they provided written informed consent and spoke the Dutch language. Participants were not expected to have knowledge of the Healthdot. Participants were purposively selected to create variation in the client population they cared for (ie, individuals with somatic and psychogeriatric conditions, individuals in short-term residential care, individuals undergoing geriatric rehabilitation, and individuals receiving acute geriatric care).

Data Collection

A semistructured interview guide (Multimedia Appendix 1) was developed by the research team (LCG, MCP, CMPMH, LMK, JS, and LWvB) and addressed the following topics: demographics, current practices regarding ARIs, digital health technologies in NH care, and the Healthdot. Prior to the discussion of the topic “Healthdot,” participants received a short presentation explaining how the Healthdot is placed, how it is used for monitoring, and its intended use in nursing homes (ie, for early detection of ARIs and detection of clinical deterioration during an ongoing ARI). More information about the Healthdot can be found at the Philips smartQare website [14]. Formally trained PhD student LG performed a pilot interview with a nurse practitioner who was formerly employed in an NH. Adjustments were made to increase understandability, which were validated by the nurse practitioner.

Interviews were conducted by LG between May 2024 and December 2024 until data saturation was reached, defined as the point during data analysis at which no new information emerged. Depending on the participant’s preference, interviews were held either via Microsoft Teams or in person at the NH. All interviews were audio-recorded. Verbatim transcripts were made, accompanied by field notes that included contextual information such as the setting, the relationship with the participant, the behavior of the participant, and reflections. The transcripts of the first 3 interviews were reviewed by senior researcher LWvB, who provided feedback to enhance the quality and consistency of subsequent interviews.

Data Analysis

Thematic analysis was used to analyze the data in accordance with the 6-phase approach described by Braun and Clarke [15]. Transcripts were read by researchers LG, MP, and LWvB themselves to familiarize with the data. Inductive coding was

XSL•FO
RenderX

performed in MAXQDA 24 (VERBI Software) [16], using a bottom-up approach to allow themes to emerge directly from the data. Two researchers independently open coded nine interviews (LG and MP or LWvB), with an equal distribution of interviews with physicians and care staff. Discrepancies were discussed until agreement was reached, contributing to a shared understanding of coding and interpretation among the researchers. The remaining 11 interviews were open-coded by LG, guided by the coding decisions and interpretations agreed upon during the initial coding phase, after which the codes were reviewed and critically appraised by either MP or LWvB. Coding was conducted iteratively, with regular discussions between researchers LG, MP, and LWvB to review coding decisions, resolve uncertainties, and ensure consistency with earlier coding. Subsequently, axial coding was conducted to identify relationships between codes and organize them into categories. This process led to the identification of overarching themes that captured the main patterns in the data. Throughout the analysis, reflexive discussions among the research team (LG, MP, CH, JS, and LWvB) helped to validate interpretations. Illustrative verbatim quotes were translated by LG and subsequently reviewed and corrected by 2 native English speakers.

Ethical Considerations

Upon review of the study protocol, the Medical Ethics Review Committee of the Amsterdam University Medical Center concluded that this study does not fall within the scope of the Medical Research Involving Human Subjects Act [17] (WMO; case 2024.0480). Participants provided written informed consent prior to the interview.

Results

A total of 20 participants were interviewed. Most participants were aged 36 to 50 years, and the sample included physicians (n=7), nurses (n=9), and other health care professionals (Table 1). Participants provided care for various NH client populations. The interviews lasted between 27 and 72 minutes (mean 47 , SD 9 min).

Table . Characteristics of participants (N=20).

[a]Multiple options possible.

Contextual Background

Current Practices in Monitoring ARIs

Participants stated that monitoring of ARIs and the frequency thereof are dependent on the treatment policies of NH clients. NH clients with a curative treatment policy (ie, full medical care including life-prolonging treatment) are monitored regularly, while NH clients with a palliative treatment policy (ie, care primarily focused on comfort, with optional life-prolonging treatment) or a symptomatic treatment policy

XSL•FO
RenderX

(ie, care limited to symptom relief, no life-prolonging treatment) are monitored sporadically or not at all. Monitoring in cases of suspected ARI is performed by nurses or certified nursing assistants, either in consultation with or under the instruction of a physician, and consists of regular measurement of vital signs (ie, heart rate, respiratory rate, temperature, blood pressure, and oxygen saturation) and clinical observations (eg, clinical condition, bed confinement, and food and drink intake). For clinical observations, particularly in clients with psychogeriatric conditions, the continuity of care staff and their familiarity with NH clients were identified as critical factors, which are currently often lacking due to staffing shortages.

Organizational Perspectives on the Use of Digital Health Technologies

Differences were identified in how the participants described the perspective of their organization on digital health technologies. Some participants stated that their organization had no focus on digital health technologies at all, while other participants stated that their organization was actively implementing new technologies. In these latter organizations, digital health technology was considered a key focus area by management, with innovation teams and designated staff members embedded. Participants from some organizations mentioned that digital health technologies were being implemented, yet a clear and structured strategy was lacking, which limited sustainable implementation. Several organizations were already using digital health technologies to monitor vital signs, including bed sensors measuring respiratory and heart rate, vital signs monitors, or standalone devices.

Individual Perspectives on Digital Health Technologies

Participants' individual perspectives on digital health technologies were generally positive, provided that their implementation serves a clear goal that is beneficial for NH clients, health care professionals, or both. Most participants emphasized the need for technology to ensure future-proof health care, with fewer health care workers and more older adults. They noted that digital health technologies can offer possibilities to this end, and can help reduce workload. However, participants stressed that technology should not replace face-to-face care, but rather support it.

Perspectives on the Use of the Healthdot

Regarding the use of the Healthdot for monitoring ARIs in NHs, 5 main themes were identified: alignment of Healthdot use and treatment policy, balancing safety and freedom, impact of the Healthdot on work processes, supporting rather than replacing care, and possible use during pandemics and in the future.

Theme 1: Alignment of Healthdot Use and Treatment Policy

Participants emphasized the importance of having a clearly defined goal when using the Healthdot, aligned with the treatment policy of NH client. The Healthdot was generally considered suitable for NH clients with an active treatment goal, such as those receiving intermediate care after hospital admission or those with a curative treatment policy. It was also highlighted that the Healthdot could be of added value when monitoring ARIs in clients with psychogeriatric conditions, as this group often has difficulties expressing their symptoms. However, these clients tend to be fidgety and may intentionally or unintentionally pull off the Healthdot:

> *Yes, in residential care for people who still want a lot [in life]. And, for example, I think it [the Healthdot] would be very good for young people with dementia living in a group. That is often a group with quite a strong desire for treatment, but who are not eager for a monitoring visit.* [R2: physician]

Some physicians were hesitant about the Healthdot's actual impact on medical management, considering the limited treatment options for viral ARIs:

> *That's where my doubt lies with viral respiratory infections. Usually, you don't do very much, except for influenza. As you said, then you prescribe Oseltamivir. But if it's just a regular respiratory virus, it's a matter of support, symptom management, but beyond that I think: what more can you do?* [R20: physician]

Most participants perceived the Healthdot as less suitable for NH clients receiving palliative or symptomatic care, as vital signs are typically no longer routinely monitored, and deviations identified by the Healthdot would have limited or no consequences for clinical treatment. Physicians, in particular, voiced stronger reservations regarding its use in this context:

> *For example, someone who says: I don't really want any life-prolonging interventions anymore. If I don't wake up tomorrow, that's fine. What do you do with that in your system in terms of signaling? It is nice to know if someone is deteriorating, but you're not going to treat them because of that, you know.* [R8: physician]

Opinions varied concerning the potential added value of the Healthdot in providing comfort-focused care. While most physicians questioned whether earlier detection by the Healthdot would result in the earlier provision of care, care staff—including nurses and certified nursing assistants—mentioned that earlier identification of distress might enable more timely comfort measures:

> *It is useful to notice if someone is restless or becomes restless. Then you can go there and check to see: what does this person need? Really offering comfort.* [R12: quality nurse]

Several ethical dilemmas were raised regarding the potential contribution of the Healthdot to a focus on life-prolonging interventions, whereas it might be more appropriate in the NH population to focus on acceptance of the finiteness of life. In the latter case, one may not want to know and control everything regarding the clinical situation, as this is also accompanied by the burden of difficult decisions for professionals, NH clients, and their relatives:

> *On the one hand, I think: no, we really need to look [at possibilities regarding the Healthdot]. On the other hand, I think, is this truly the direction in which we should be heading, or should we also, at some*

XSL•FO
RenderX

> *point, simply accept that life is finite? And that sometimes, it's just the flu [you die of], so to speak. Of course, that's not a very politically correct thing to say, and it's very nuanced. I'm putting it quite bluntly now, but of course we're talking about people. There is also value in being ill in a nursing home, you know. Life is still meaningful then.* [R4: nurse practitioner]

> *Sometimes it is good to not always know, right? If someone significantly deteriorates without anyone noticing and then perhaps passes away, that can sometimes be a good thing. That not everyone knows, because if you know something, you also have responsibilities. […] For families it is often very difficult to have an opinion about this and it can be better if someone suddenly deteriorates rapidly and dies. Then it just is what it is.* [R6: physician]

Some participants mentioned the shift in Dutch NHs from a medical model toward a well-being and homelike model, which they perceived as conflicting with the implementation of the Healthdot. Nevertheless, other participants recognized that medical elements can still be necessary to support the well-being of NH clients:

> *The most important point is, then we're investing more in curative care, while I think that it should be more about well-being. So, I just wouldn't allocate more budget to further increase the intensity of curative care. We really need to realize that the average length of stay in a nursing home is only a few months, so what are we talking about? It's about making sure they have a good day, period.* [R1: physician]

Overall, a clear distinction emerged between physicians and care staff. Physicians tended to evaluate the Healthdot in terms of its relevance for treatment decisions and were, therefore, more critical in situations where monitoring was unlikely to influence clinical management. In contrast, care staff were generally more positive about its use, as they emphasized its potential to support the early recognition of changes in NH clients' conditions and to guide timely treatment- and comfort-focused care.

Theme 2: Balancing Safety and Freedom

Participants acknowledged that the Healthdot can influence both the safety and freedom of NH clients in positive and negative ways. They mentioned that the Healthdot could enhance safety by allowing earlier detection of deterioration and providing NH clients and their families with a sense of safety. At the same time, some NH clients may perceive this as a form of surveillance and a breach of their privacy. Additionally, restrictive measures taken in response to Healthdot alerts, such as isolating NH clients when an infection is suspected based on an elevated heart or respiratory rate, could be experienced as stressful and limit their freedom:

> *Yes, there is a strong view that no [restrictive] measures should be taken, because freedom is prioritized. That's really the tendency, more freedom, so we generally don't want restrictive measures.* [R6: physician]

Simultaneously, care staff identified potential benefits of the Healthdot in supporting NH clients' sense of freedom by reducing interference in daily life. Participants mentioned that the Healthdot could decrease the need for manual measurements, which are often experienced as burdensome, and eliminate nightly visits, thereby positively impacting sleep quality and recovery. For NH clients who are aggressive or refuse manual measurements, the Healthdot was seen as a less intrusive and more practical alternative.

> *You can't just keep opening doors all the time. People want to sleep, so how useful would it be if you just have a screen that allowed you to continuously monitor vital signs. That if there is an acute situation, you'd already be there before that acute situation.* [R17: nurse]

Altogether, both physicians and care staff acknowledged the potential impact of the Healthdot on safety and freedom. However, the perceived benefits in terms of reducing burden and supporting NH clients' freedom were primarily emphasized by care staff, whereas physicians did not explicitly highlight these aspects.

Theme 3: Impact of the Healthdot on Work Processes

Participants mentioned that the Healthdot could reduce the workload for care staff, by limiting the need for frequent manual measurements. This would also allow care staff to visit upon indication, for example, when an early warning signal is triggered by a prolonged elevated heart rate:

> *I think that it's efficient. I think that maybe you can say that you don't need to do checks 3 times a day, unless, for example, the dashboard of the Healthdot system shows abnormalities.* [R18: nurse]

Care staff expected that this would allow more time for other tasks and increase opportunities for personal interaction with NH clients. The Healthdot was particularly seen as valuable in intermediate care settings, where most monitoring takes place:

> *I think it [use of the Healthdot] also means more time for the clients. Sometimes you feel like you're just going from one client to the next, with multiple tasks. […] I think it would be really nice to have more time for a real conversation with someone, or to actually dive a bit deeper.* [R11: nurse]

Contrarily, some physicians expressed concerns that the Healthdot would increase their workload. They emphasized the large number of measurements and early warning signals generated by the device, along with the responsibility associated with interpreting and acting on these signals. They pointed out that, in medical practice, "measuring is knowing," and with that knowledge comes the responsibility to act. Additionally, concerns were raised about the potential for false-positive signals, particularly in this population where vital signs often deviate from the norm:

> *The more data you collect, the more you have to account for. Because all the data you receive, requires*

XSL•FO
RenderX

> *a response. As a physician, you have to relate to it. You're responsible for it. So, I don't want to know.* [R1: physician]

At the same time, participants acknowledged that the Healthdot could provide consistent, timely, and objective measures. These are often lacking, as measurements are regularly not or not adequately performed in practice. Respiratory rate was particularly regarded as a valuable addition, considering that there is currently no measurement equipment for this:

> *At least you're somewhat less dependent on whether care staff is going to do it [measuring vital signs] or not. So, that could be an advantage. Yes, so especially that you get more consistent and reliable input, whereas now it is often not consistent and also not always reliable.* [R8: Physician]

Nevertheless, participants highlighted that manual measurements would remain necessary, as the Healthdot does not measure all required vital signs, such as temperature, blood pressure, and oxygen saturation. It was stated that these parameters could be measured based on indications from the Healthdot, such as elevated heart or respiratory rates, instead of on a routine basis. Some physicians mentioned that the current level of monitoring by care staff is sufficient, suggesting that the Healthdot is not necessary.

The main difference between physicians and care staff within this theme concerned the perceived workload. While both groups agreed that the Healthdot would likely reduce the workload for care staff, physicians expressed concerns that their workload could increase. Care staff generally did not consider this potential impact on physicians.

Theme 4: Supporting Rather Than Replacing Care

Although participants recognized that the Healthdot could reduce workload, they emphasized that the device cannot replace care staff. Physicians, in particular, noted that observations made by care staff provide more valuable insights than measurements, especially when providing care focused on comfort:

> *Yes, then the question really is what … are they in pain at that moment? Is that why their respiratory rate is going up? Or is it actually the final phase [of their life]? Usually, the respiratory rate doesn't increase just like that. People will become restless, start moving, and that's often already a signal.* [R6: physician]

They also stressed the importance of ensuring that the Healthdot does not lead to a reduction in personal contact with NH clients, as this is often perceived as highly valuable. Care staff themselves generally did not share these concerns. Finally, costs were identified as an important factor. Participants noted that while the Healthdot is expensive, it cannot replace care staff. Therefore, the added value of the Healthdot must be substantial before an organization will consider its implementation.

Theme 5: Possible Use During Pandemics and in the Future

The possible use of the Healthdot during future pandemics or outbreaks was discussed in a few interviews. Although some participants viewed this as a promising application, others were hesitant, referring back to the balance between safety and freedom:

> *During COVID, it would have been nice if you could have seen in advance that someone's heart rate was rising. He develops fever, so he might have COVID, so you could have put him in quarantine earlier. But it's also a bit scary, because as soon as you, say, sneeze once, you might already have to go into quarantine, because that thing measures it all.* [R3: physician]

Moreover, some participants emphasized the potential value of the Healthdot in light of an anticipated future with fewer health care professionals available and a growing aging population. In this context, the Healthdot could support sustainable care delivery in NHs:

> *It's a necessity. It's an absolute necessity. We simply have no other choice, so I definitely think we should move in that direction. We shouldn't wait too long either, because if the statistics are correct, the staffing shortages will become very severe in the coming years.* [R14: quality nurse]

Preconditions for Using the Healthdot

One important precondition stated was the usability of the Healthdot. Participants mentioned that the device should be easy to use, allow monitoring from devices they currently use, be integrated into the electronic health records of NH clients, and be able to measure additional vital signs (ie, temperature, oxygen saturation, and blood pressure). It also needs to be trustworthy, and the early warning signal must be adjustable so that receiving too many false signals can be avoided. Moreover, participants pointed out that the Healthdot is single-use, suggesting that more sustainable alternatives should be explored.

Participants emphasized that successful implementation of the Healthdot requires a support base among care staff. They stated that this can be established by including them during the implementation process and incorporating their feedback. Several participants stated that it is essential to have enough care staff who are knowledgeable and skilled in using the Healthdot, suggesting that a dedicated team member could take the lead. Additionally, adequate training and guidance during the use of the Healthdot were emphasized as important, ensuring confidence for care staff.

Another precondition mentioned by several participants was the need for clear communication with NH clients and their families about expectations regarding the use of the Healthdot. Physicians stressed that it is crucial to prevent unrealistic expectations, for example, regarding how frequently the physician will review the data. They mentioned that some relatives may, at times, demand more than is feasible or preferable. Therefore, several participants recommended limiting NH clients' and relatives' access to the Healthdot data:

> *What I'm a bit worried about is that family members have unrealistic expectations. That you'll be at the*

XSL•FO
RenderX

> *bedside within 5 minutes. That you'll be held accountable for that, in a way.* [R3: physician]

Finally, a clear policy regarding the use of the Healthdot is needed, according to the participants. They noted that it should be clear for whom, when, and for what purpose using the Healthdot is appropriate. Moreover, clear instructions should be available that specify by whom early warning signals are followed up and which actions need to be taken. Participants also mentioned the need for clarifying roles and responsibilities, suggesting that care staff should be responsible for monitoring, while physicians provide clinical guidance and assess the progression of the infection.

Discussion

Principal Findings

This qualitative interview study provides valuable insights into health care professionals' perspectives on the use of the Healthdot for monitoring ARIs in NHs. While care staff were generally positive about the Healthdot, physicians' attitudes were mostly reserved, highlighting the need for careful consideration of the NH context and its associated complexities during potential implementation. Our findings show that implementing wearable continuous vital signs monitoring devices in this setting extends beyond clinical purposes and necessitates careful weighing of the NH client's treatment goals, ethical considerations, the balance of safety and freedom, its impact on care processes, and the importance of supporting rather than replacing personalized care.

Although perspectives of health care professionals on wearable continuous vital signs monitoring have been studied before in hospital settings, to our knowledge, we are the first to study these perspectives in the NH setting. A previous study by Weenk et al [18] found that hospital-based health care professionals were generally positive about continuous vital signs monitoring, whereas more reserved attitudes toward this were identified in our study. This difference might be explained by the context of NHs, where health care professionals must balance clinical care with NH clients' quality of life and a home-like environment. Participants raised ethical concerns regarding the use of the Healthdot, particularly in palliative care situations, as they expressed fears that the Healthdot might lead to life-prolonging care in these cases, instead of promoting comfort and well-being. Nevertheless, van der Steen et al. [19] emphasize that careful and timely recognition and management of symptoms are crucial for enhancing well-being in palliative care [19]. From this perspective, the Healthdot could potentially contribute to person-centered palliative care by supporting the timely recognition and relief of symptoms.

The balance between safety and freedom is a recurring topic in NH care that was also reflected in our findings. Participants noted that the Healthdot could enhance safety by enabling early detection of deterioration caused by ARIs and offering a sense of security, which is in line with findings from another study focusing on monitoring devices in NHs [20]. However, participants in our study also raised concerns about the impact of the Healthdot on NH clients' freedom, including feelings of being watched, privacy intrusion, and restrictive infection control measures. The COVID-19 pandemic demonstrated how such measures affected NH clients' autonomy and mental well-being [21]. Still, the relationship between freedom and care in NHs remains complex. It has been argued that some degree of intervention is always required in institutional care, making autonomy and freedom in this context not straightforward [22]. Haslam-Larmer et al [23] highlighted similar tensions in the context of location monitoring in dementia care, where privacy is often considered secondary to safety concerns [23]. Interestingly, participants also saw potential for the Healthdot to enhance NH clients' sense of freedom by reducing the need for manual measurements and nighttime disruptions. This aligns with findings from Emilsson et al [24], where NH staff reported that camera surveillance monitoring reduced unnecessary night-time visits [24]. To effectively balance safety and freedom, it is essential to consider the individual needs of each NH client, as the value placed on safety or freedom may differ for everyone.

A potential consequence of reducing manual measurements is a decrease in contact moments, which both physicians and care staff in our study considered essential for maintaining clinical insight and relationships. This concern is widely recognized across studies on both surveillance and vital signs monitoring in several care settings [18,24-26]. For instance, it was reported that continuous vital sign monitoring in hospitals may reduce bedside contact and compromise clinical judgment, as such systems cannot assess subjective experiences like pain [18,25,26]. Similarly, research on surveillance monitoring in NHs highlights the irreplaceable value of physical presence for both clinical observation and emotional reassurance [24]. However, Niemeijer et al [22] suggest that monitoring technologies do not necessarily reduce human contact, as during their study on surveillance technologies in residential facilities, nurses continued their rounds and maintained strong relationships [22]. In our study, participants also expected contact to remain necessary, as the Healthdot does not measure all vital signs needed for monitoring of ARIs and manual measurements are still required when indicated by the early warning signal. Moreover, both our findings and previous research suggest that time saved through monitoring may be reinvested in client-related tasks [18,22]. Nevertheless, with the expected increase in older adults in NHs and staff shortages [2,3], there is a risk that any time gained will be used to manage higher caseloads, potentially limiting opportunities for personal interaction.

Despite expectations that the Healthdot could save time for person-centered care, physicians in our study raised concerns about a possible increase in workload. Similar concerns have been reported in studies conducted in hospital settings, where the high frequency of measurements was found to burden physicians [18]. In line with our findings, several studies identified false-positive alerts as a contributor to "alarm fatigue," further adding to the workload [18,22]. Physicians in our study also expressed concerns about the increased burden of responsibility that comes with more measurements. NH clients and their relatives might have unrealistic expectations, assuming immediate intervention when measurements deviate. Previous research has shown that unrealistic demands from family

XSL•FO
RenderX

members are a recurring challenge in NHs and can contribute to staff stress [27]. Managing expectations is, therefore, crucial for sustainable use.

Notably, our findings revealed differing perspectives between physicians and care staff regarding the use of the Healthdot. Across themes, we found that care staff were generally enthusiastic, viewing the device as a way to reduce workload, increase time for personal interaction, and enhance the freedom and well-being of NH clients. Physicians, however, expressed more critical views, raising concerns about the Healthdot's impact on clinical management, increased workload and responsibility, and potential implications for person-centered care. These differences may be explained by the distinct roles and responsibilities that physicians and care staff have within interprofessional collaboration, as described by Schot et al [28]. Whereas physicians may see the Healthdot primarily as a diagnostic tool requiring clinical action and interpretation, nurses may view it mainly as a support system in their caregiving routine, evaluating it in terms of practicality, efficiency, and NH clients' comfort. Recognizing these divergent perspectives is essential, as they may influence acceptance, integration into care routines, and overall effectiveness. This suggests that the successful implementation of the Healthdot will require clear communication, alignment on its intended purpose, shared understanding of its role in care practices, and active collaboration between health care professionals. Additionally, acceptance is influenced by the nursing home's organizational culture and leadership supporting innovation [29].

One limitation of this study is that the Healthdot is not currently used for monitoring ARIs in NHs, meaning that participants had to speculate about its potential use. This hypothetical context limited the extent to which their responses reflect real-world experiences or challenges and led some participants to reflect on the general use of the Healthdot in NHs rather than specifically for monitoring ARIs. Nonetheless, a strength of this study lies in its early involvement of end users, reflecting a growing emphasis in implementation research [30] and providing early insights, considerations, and key prerequisites for potential implementation. Additionally, our participants stressed the importance of including their perspectives to enhance acceptance and practical relevance, which aligns with evidence that such engagement fosters organizational readiness through an innovative culture and shared commitment [31,32]. Although some participants did have prior experience with the Healthdot in a research context due to their participation in the quantitative PRIMA study, this experience was limited to the placement of the Healthdot and did not involve monitoring with the Healthdot. No differences in responses were observed between participants with and without this prior experience.

Conclusions and Implications

Our findings demonstrate that implementing continuous vital signs monitoring devices, such as the Healthdot in NHs, involves multiple considerations and conditions, shaped by the complexity of this care setting. A tailored assessment is essential for each NH client, taking into account factors such as treatment goals, safety, autonomy, and person-centered care. Clear communication and alignment between physicians and care staff, as well as between NH staff and relatives of NH clients are crucial, particularly regarding expectations about the Healthdot's impact on care processes. Although this study focused on ARIs, many insights may be relevant to the broader application of monitoring devices in NHs. This study offers practical guidance and key considerations that may inform future implementation efforts of continuous vital signs monitoring devices in this setting.

Acknowledgments

The authors thank the nursing home health care professionals who participated in the interviews. Additionally, the authors thank Jessica Williams and Tony Williams for their assistance in translating the interview quotes, as well as Kelly Paap for participating in the pilot interview. Generative artificial intelligence tools were used to assist with proofreading and language editing of the text.

Funding

This work was funded by ZonMW (project 10430362220010). The funder had no involvement in the study design, data collection, analysis, interpretation, or writing of the manuscript.

Data Availability

Due to the sensitivity of the data, the dataset will not be shared publicly.

Abstract

Background: Training programs help dementia care staff handle residents' behavioral symptoms in nursing homes and assisted living facilities. However, it is unclear how feeling well-prepared from such training relates to experiences of physical and verbal aggression from residents.

Objective: This study aimed to determine whether perceived training preparedness was related to experiences of physical and verbal aggression from residents in nursing homes and assisted living facilities using data from a large, nationally representative dementia care workforce sample.

Methods: This study was an analysis of the 2024 National Dementia Workforce Study, a cross-sectional online survey of the national dementia care workforce. Weighted regression modeling was used to identify associations between feeling well-prepared by training programs and experiencing physical or verbal aggression.

Results: Dementia care staff in nursing homes (weighted n=896,320) commonly reported experiencing physical (365,452/896,320, 40.8%) and verbal (470,536/896,320, 52.5%) aggression from residents with dementia, whereas more than two-thirds (614,561/896,320, 68.6%) reported feeling that their training prepared them well to manage resident behaviors. Staff in assisted living facilities (n=738,856) less commonly reported experiencing physical (198,964/738,856, 26.9%) and verbal (223,343/738,856, 30.2%) aggression, whereas almost three-quarters (527,621/738,856, 71.4%) reported feeling that their training prepared them well to manage resident behaviors. In regression modeling in nursing homes, feeling well-prepared by training for managing resident behaviors was associated with a lower likelihood of experiencing physical aggression (odds ratio [OR] 0.4, 95% CI 0.223-0.711; *P*=.01) and verbal aggression (OR 0.5, 95% CI 0.299-0.844; *P*=.02). In assisted living facilities, feeling well-prepared by training for managing resident behaviors was associated with a lower likelihood of experiencing physical (OR 0.14, 95% CI 0.04-0.55; *P*=.01) and verbal (OR 0.07, 95% CI 0.0134-0.354; *P*=.001) aggression.

Conclusions: While physical and verbal aggression from residents with dementia is common in nursing homes and assisted living facilities, nationally representative weighted regression modeling highlights an association between feeling well-prepared to handle resident behaviors and a lower likelihood of experiencing aggression. As the data used were derived from a cross-sectional survey, the causal link between these 2 factors should be explored in interventional studies. Our results indicate that effective training programs are associated with worker-reported reduced experiences of physical and verbal aggression in both nursing homes and assisted living facilities. The specific components of training programs that may support effectiveness remain unknown.

Introduction

Aggression is a behavioral symptom of dementia that manifests as physically or verbally hostile or violent behavior [1]. Physical aggression includes striking, kicking, hair pulling, spitting, and throwing things, whereas verbal aggression includes swearing, insulting, threatening, or verbal sexual harassment [2]. Physically and verbally aggressive behaviors are common in residential facilities such as nursing homes and assisted living facilities, with estimates indicating aggression in 51% of patients with dementia in these facilities [3]. Staff exposure to aggression is associated with a higher likelihood of burnout and physical harm, including bruising and lacerations, and contributes to workforce turnover [4].

General nursing training programs rarely include focused training on managing the behavioral symptoms of dementia, including aggression [5]. While some licensed professional roles (eg, registered nurses and licensed practical nurses) require prerequisites and standardized competencies, the unlicensed direct care workforce receives limited formal education and highly variable on-the-job training. Studies and workforce reviews describe unlicensed direct care workers as underprepared for dementia-related agitation and aggression despite providing hands-on care to people with dementia [6,7]. In nursing education, dementia-specific content is inconsistently integrated into prelicensure curricula and taught under broad geriatric instruction rather than as a distinct competency, although proposed dementia-specific training programs have identified the management of aggression and agitation as a core competency for future training development [8].

There is a gap in the evidence on the effectiveness of training on the experience of physical or verbal aggression in nursing home or assisted living facility staff. Demonstrated differences in the effect of training programs are unclear, and studies are limited by small, nongeneralizable samples [9]. There is an opportunity to determine whether there is an association between training programs and the experience of physical or verbal aggression by staff in nursing homes and assisted living facilities using a survey that provides a nationally representative sample. Understanding whether training programs can mitigate occupational exposures to aggression may support interventions to reduce future workforce turnover [4].

The objective of this study was to leverage a newly released, nationally representative sample of the US paid dementia care workforce to determine the prevalence of physical and verbal aggression and whether there was an association between training programs and the frequency of physical or verbal aggression. We hypothesized that effective training would be associated with a reduction in the experience of physical and verbal aggression from residents. By identifying the association using a large, weighted, nationally representative dataset, we can inform policy, training standards, and workforce development to support the paid dementia care workforce in the United States.

Methods

Data

This study used wave 1 (2024) data from the nursing home and assisted living surveys collected by the National Dementia Workforce Study (NDWS) [10]. The NDWS is a multiyear, federally funded data infrastructure initiative designed to generate nationally representative data on the US dementia care workforce. The study conducted a 2-stage cluster sampling design of establishment- and individual-level participants from nursing homes and assisted living facilities to produce probability-based estimates of the national dementia care workforce population [11]. Survey weights were developed by NDWS statisticians and survey designers to permit nationally representative inference at the organization and staff levels, accounting for complex survey design, stratification, and clustering.

Ethical Considerations

This study was approved by the University of Alabama at Birmingham Institutional Review Board (IRB-300015390). This analysis and reporting adhered to the Reporting of Studies Conducted Using Observational Routinely-Collected Data (RECORD) statement for the reporting of studies conducted using observational data.

Dependent Variables

Our primary dependent variable was the presence or absence of physical or verbal aggression. To classify physical or verbal aggression, we used question 42 on the nursing home and assisted living surveys, which reads “In your job at this community over the past year, how often have you experienced the following?” We assessed the presence of physical aggression using subitem I, which reads “Hitting or other physical aggression from residents,” and verbal aggression using subitem J, which reads “Yelling or other verbal aggression from residents.” Potential responses were “never,” “rarely,” “sometimes,” and “often.” We dichotomized these variables as “not frequently” (encompassing “never” or “rarely”) and “frequently” (encompassing “sometimes” or “often”) because the original distribution did not meet the proportional odds assumptions of the Brant test, precluding analysis via linear or ordinal logistic regression.

Training was operationalized to reflect respondents’ perceived preparedness to manage aggressive behaviors in residents with dementia rather than the presence or absence of specific training modalities. Although the NDWS wave 1 surveys include items assessing exposure to formal and informal dementia-specific training (items NH4 and NH5 for nursing homes and AL4 and AL5 for assisted living facilities), these items ask broadly about training. Because the primary focus of this analysis was preparedness to handle aggressive behaviors, we used the global preparedness items (NH6 and AL6), which ask respondents whether their training prepared them to care for residents with dementia. These items capture respondents’ self-assessment of readiness rather than training format and were therefore better aligned with our analytic objective of examining perceived preparedness for challenging behavioral situations.

Independent Variables

Independent variables included sex, age, race, ethnicity, feeling well-prepared by training to manage participant behaviors, rurality, and licensure. Licensure was determined by currently holding a registered nurse or licensed practical nurse license, whereas "nonlicensed" encompassed all other nonlicensed staff, including certified nursing assistants, home health aides, and medication assistants. We also included variables for directly working with residents and being a double-duty caregiver, where a staff member also provided care for an adult child at home.

Table 1 shows the variables and their item numbers and operationalizations.

Table . Variables, item numbers, and operationalizations.

Analytic variable	NDWS[a] item number	Item wording (abbreviated)
Licensure	NH1 or AL1	Do you currently hold any professional license(s)?
Direct care	NH35 or AL35	Do you provide direct care to residents with Alzheimer's disease or other dementias?
Educational level	NH3 or AL3	What is the highest level of education you have completed?
Sex	NH56 or AL56	What is your sex? (Male or female; masked in PUF[b])
Age (mean, SD, and range)	NH48 or AL48	What year were you born? (Used to calculate age; masked in PUF)
Race	NH50 or AL50	What is your race? (Categories masked or collapsed in PUF)
Ethnicity	NH49 or AL49	Are you Hispanic, Latino/a, or of Spanish origin?
Family caregiver	NH37a-f or AL37a-f	Are you currently or have you ever been a family caregiver for a person with Alzheimer's disease or other dementias? (Item series)
Physical aggression	NH38a-i or AL38a-i	How often have residents you care for done the following... (eg, hit, kicked, or physically hurt someone)?
Verbal aggression	NH38a-i or AL38a-i	How often have residents you care for yelled at, threatened, or verbally abused staff?
Training preparedness	NH6 or AL6	Overall, how well did your training prepare you to care for residents with Alzheimer's disease or other dementias?
Rurality	Derived (facility level)	Rural vs nonrural classification derived from facility geographic indicators described in the NDWS wave 1 survey report (not a single staff-reported item)

Statistical Analysis

Overview

Descriptive statistics were used to summarize the characteristics of the included formal caregivers. Means and SDs were reported for continuous variables, whereas frequencies and percentages were reported for categorical variables. All descriptive estimates account for the complex survey design using the NDWS-provided sampling weights. All analyses were conducted in R (3.4.2; R Foundation for Statistical Computing). Missing data were handled via listwise deletion and were not imputed given the large, weighted sample size and the potential for weighted imputation to bias results.

Univariate Modeling

Chi-square and 2-tailed *t* tests were used to examine the association between the independent variables and a dichotomous high vs low frequency of experiencing physical or verbal aggression from residents.

Regression Modeling

Penalized logistic regression models using the Firth bias-reduced likelihood were fit to determine the strength and direction of the effect of feeling well-prepared by training programs on the dichotomous high vs low frequency of experiencing physical or verbal aggression from residents in nursing homes or assisted living facilities. NDWS-provided survey weights were used to represent the national dementia care workforce population. Clustering was accounted for in the survey object by specifying the primary sampling unit rather than a random effect included

XSL•FO
RenderX

in the regression model as the cluster is a product of the NDWS sampling scheme rather than a multilevel structure of interest. Variance inflation factors were used to identify potentially problematic collinearity, with a variance inflation factor threshold of 10 or higher identified as problematic collinearity.

Supplementary Analysis

We compared respondents included in the regression models (complete cases) with the full survey sample for our variables of interest, incorporating survey weights. We also conducted an additional supplementary regression model that included ethnicity, despite ethnicity exhibiting potentially problematic collinearity, due to the established importance of ethnicity in the dementia care workforce [12,13].

Results

Overview

The dementia care workforce in nursing homes (n=896,320) was primarily female (828,558/896,320, 92.4%), White (440,158/896,320, 49.1%), and non-Hispanic (778,249/896,320, 86.8%), with a mean age of 41.49 (SD 12.65) years. Less than half (365,452/896,320, 40.8%) reported frequently experiencing physical aggression from residents, whereas more than half (470,536/896,320, 52.5%) reported frequently experiencing verbal aggression from residents. More than two-thirds (614,561/896,320, 68.6%) reported feeling that their training prepared them well to manage resident behaviors.

The dementia care workforce in assisted living facilities (n=738,856) was primarily female (631,070/738,856, 85.4%), White (490,181/738,856, 66.3%), and non-Hispanic (650,020/738,856, 88%), with a mean age of 41.36 (SD 13.94) years. More than one-quarter (198,964/738,856, 26.9%) reported frequently experiencing physical aggression from residents, whereas just under one-third (223,343/738,856, 30.2%) reported frequently experiencing verbal aggression from residents. Almost three-quarters (527,621/738,856, 71.4%) reported feeling that their training prepared them well to manage resident behaviors.

Univariate Modeling

In univariate modeling in nursing homes, race (*P*=.03) and training preparedness (*P*=.002) were associated with experiencing physical aggression. Family caregiver status (*P*=.04) and training preparedness (*P*=.01) were associated with experiencing verbal aggression.

In univariate modeling in assisted living facilities, race (*P*=.002) and training preparedness (*P*<.001) were associated with experiencing physical aggression. Sex (*P*=.02), race (*P*=.002), and training preparedness (*P*<.001) were associated with experiencing verbal aggression.

Table 3 shows the univariate modeling results.

Table . Univariate modeling results.

	Assisted living facilities, *P* value		Nursing homes, *P* value	
	Physical aggression	Verbal aggression	Physical aggression	Verbal aggression
Age (mean and SD)	.49	.36	.18	.35

Regression Modeling

In the fully adjusted model estimating the likelihood of reporting frequent physical aggression in nursing homes, feeling well-prepared by training for managing resident behaviors (odds ratio [OR] 0.40, 95% CI 0.223-0.711; *P*=.01) was associated with a lower likelihood of reporting frequent physical aggression.

In the fully adjusted model estimating the likelihood of reporting frequent verbal aggression in nursing homes, feeling well-prepared by training for managing resident behaviors (OR 0.50, 95% CI 0.299-0.844; *P*=.02) was associated with a lower likelihood of reporting frequent verbal aggression.

In the fully adjusted model estimating the likelihood of reporting physical aggression in assisted living facilities, feeling well-prepared by training for managing resident behaviors (OR 0.14, 95% CI 0.036-0.556; *P*=.01) and being a family caregiver (OR 0.19, 95% CI 0.043-0.778; *P*=.03) were associated with a lower likelihood of reporting frequent physical aggression.

In the fully adjusted model estimating the likelihood of reporting verbal aggression in assisted living facilities, working in a direct care role (OR 5.09, 95% CI 1.223-21.194; *P*=.03) was associated with a higher likelihood of reporting frequent verbal aggression, and feeling well-prepared by training for managing resident behaviors (OR 0.07, 95% CI 0.014-0.354; *P*<.001) and being a family caregiver (OR 0.18, 95% CI 0.061-0.516; *P*<.001) were associated with a lower likelihood of verbal aggression.

Supplementary Modeling

Sensitivity Analysis

In the sensitivity analysis, we did not find statistically substantial differences between the complete-case sample included in the regression modeling and those who were missing data for key demographic variables (Table 5).

Table . Sensitivity analysis comparing complete cases.

Variable	Nursing homes, *P* value	Assisted living facilities, *P* value
Age	.14	.64
Sex	.23	.13
Race	.62	.23
Training preparedness	.55	.91
Ethnicity	.24	.32

Regression Modeling

In the supplementary analysis of assisted living facilities, feeling that training prepared them well for managing resident behaviors (OR 0.13, 95% CI 0.04-0.56; *P*=.01) and family caregiver status (OR 0.20, 95% CI 0.05-0.75; *P*=.03) were associated with a lower likelihood of reporting frequent physical aggression. Hispanic ethnicity (OR 14.03, 95% CI 2.77-71.01; *P*<.001) was associated with a higher likelihood of reporting frequent physical aggression.

In the supplementary analysis of assisted living facilities, a direct care role (OR 4.74, 95% CI 1.21-18.68; *P*=.04) was associated with a higher likelihood of reporting frequent verbal aggression. Family caregiver status (OR 0.18, 95% CI 0.06-0.51; *P*<.001) and feeling prepared by training (OR 0.07, 95% CI 0.01-0.37; *P*=.01) were associated with a lower likelihood of reporting frequent verbal aggression.

In the supplementary analysis of nursing homes, feeling prepared by training (OR 0.48, 95% CI 0.26-0.89; *P*=.03) was associated with a lower likelihood of reporting frequent verbal aggression.

Discussion

Overview of Findings

In both nursing homes and assisted living facilities, training programs for handling resident behaviors were associated with a lower likelihood of experiencing physical aggression, and in assisted living facilities, these training programs were associated with a lower likelihood of experiencing verbal aggression.

Comparison With Prior Literature

Prior work emphasizes the importance of dementia-specific training to manage resident behaviors. Livingston et al [14] demonstrated in a systematic review of 33 studies that aggression can be mitigated through caregiver activities, especially person-centered approaches to care that systematically support resident behaviors. Other reviews have found that aggression prevention in residential facilities requires staff to be equipped with knowledge and skills to intervene early to prevent situational escalation into physically or verbally aggressive behaviors, although Seitz et al [15] concluded that large-scale studies of staff training in nursing homes and residential facilities should examine whether these results are robust beyond protocol-driven interventions. Our results indicate that, on a nationally representative scale, there is an association between a reduced frequency of aggressive behaviors and perception that trainings prepared staff to manage participant behaviors. While the cross-sectional nature of the NDWS precludes causal speculation, other work has hypothesized that training that includes early recognition and intervention for problematic behaviors can reduce aggression in residents with dementia [16,17].

Our finding that being a double-duty caregiver, or caring for a person at home, was associated with a reduced likelihood of experiencing aggressive behaviors in assisted living facilities was initially surprising. However, this correlation could be due to their experience in understanding and recognizing escalating cascades of behaviors when caring for another person in the home [18]. Limited literature exists to determine the specific skills that double-duty caregivers apply in both home and long-term care settings, although a future study could determine the influence of home-based caregiving on long-term care strategies to manage aggression.

Limitations

The large, well-conducted survey methodology and robust weighting procedures provide strength to our findings. However, care is needed in the interpretation of results due to the cross-sectional nature of the study; causality cannot be assumed. Our findings indicate that perceived training efficacy for managing resident behaviors was linked to a decrease in the frequency of aggressive incidents; however, the specific elements of the training contributing to this effect remain undetermined. On the other hand, staff experiencing lower aggression may create the perception that their training sufficiently prepared them to manage resident behaviors. Future interventional work should determine the causal path.

XSL•FO
RenderX

Additionally, the study power was limited by the initial sampling frame rather than the weighted sample. There could have been aspects of the study sample that biased the results, although the robust weighting procedures and clustering in the survey design should mitigate this effect. We treated training preparedness as dichotomous due to small cell sizes in the "not at all prepared" group. While this speaks to the level of training received at nursing homes and assisted living facilities, future work should determine whether there is a stepwise change between similar categories as there could be a meaningful difference between feeling not at all prepared and somewhat prepared.

Conclusions

In a nationally representative sample of the dementia care workforce, effective training programs were associated with worker-reported reduced experiences of physical and verbal aggression in both nursing homes and assisted living facilities. The specific components of training programs that may support effectiveness remain unknown.

Abstract

Background: Proxy-rated questionnaires remain the standard for the assessment of activity and sleep for people with dementia living in nursing homes. Sensing technologies, such as wearables, can generate continuous data that provide quantitative insights into daily activities and behavioral and psychological symptoms, such as sleep disturbance. This study explores the use of sensing technologies in the detection of changes in physical activity levels and sleep behaviors over time.

Objective: This study aims to explore the long-term capabilities of multimodal sensing technologies for assessing physical activity levels and sleep quality using selected digital biomarkers for nursing home residents with dementia. Objectives were for observation to be aligned with real-world conditions in which such sensing technologies would be applied within a nursing home environment and to assess whether distinct differences in selected digital biomarkers can be observed accurately and reliably longitudinally.

Methods: This study included 11 participants (79 - 93 y) recruited from 2 dementia care units in Norway. A smartwatch (Garmin Vivoactive 5 or Garmin Venu 3) and a radar-based system (Vital Things, Somnofy) were used to collect 7 days and 6 nights of data on physical activity levels and sleep quality at baseline, 6 months, and 1 year. The Personal Self-Maintenance Score and Neuropsychiatric Inventory–Nursing Home Version (nighttime behaviors section K) were also administered. Digital biomarkers included Euclidean norm minus one (ENMO), sleep efficiency (SE), wake after sleep onset (WASO), sleep regulatory index (SRI), sleep fragmentation index (SFI), total sleep time (TST), and time out of bed (no presence).

Results: A total of 9 participants were included in the final analysis. Differences were found in nighttime ENMO (P=.01) and in 4 of the sleep biomarkers: TST (P=.02), SE (P=.02), WASO (P=.01), and SRI (P=.01). The long-term reliability of the group ENMO was poor (intraclass correlation coefficient 0.00 - 0.02); however, it was moderate to strong (0.58 - 0.79) between individuals at each time point. The adherence and acceptability of the technologies was high (88%-96%), and the application of the devices was well tolerated by the participants, with no adverse events.

Conclusions: The use of sensing technologies could enable more objective, data-driven future care models for people with dementia residing in nursing homes; however, the results emphasized in this study require the recommendation for cautious, well-designed use of digital biomarkers for clinical decision-making.

Introduction

Background

The global prevalence of dementia is expected to reach 139 million by 2050 [1], and in countries such as Norway, more than two-thirds of nursing home residents live with dementia [2]. Monitoring neuropsychiatric symptoms (NPSs) and changes in physical activity typically relies on proxy-rated assessments, which are limited by subjectivity, retrospective bias, and low sensitivity to subtle or short-term change [3]. As health care systems face increasing workforce shortages, there is a growing need for scalable, objective approaches that can support continuous monitoring and individualized care [4]. Recent

XSL•FO
RenderX

advances in sensing technologies, including wrist-worn wearables and contactless radar systems, offer minimally obtrusive, real-time data collection in naturalistic environments and may help address these challenges.

Physical inactivity is widespread in nursing home environments [5,6], with daily routines dominated by sedentary behaviors such as sitting, resting, and sleeping [7]. Despite the importance of physical activity for maintaining function, there are no standardized recommendations for activity dosage in people with advanced dementia [8]. Although the relationship between daytime activity and sleep quality remains insufficiently understood, several studies suggest that higher daytime activity may be associated with improved sleep [9,10]. Functional ability is typically assessed using proxy-rated activities of daily living (ADL) questionnaires, but these tools are retrospective and infrequently administered, reducing their use for detecting early or subtle decline, which is an important limitation given the strong association between functional loss and increased morbidity and mortality [11].

Accelerometry provides several methods for quantifying physical activity, including step counts, intensity, frequency, and vector magnitude [12], and common metrics derived from raw acceleration data include Euclidean norm minus one (ENMO), mean amplitude deviation (MAD), Monitor-Independent Movement Summary (MIMS), activity index, and Rate of Change Acceleration Movement (ROCAM) [12,13]. A recent feasibility study in nursing home residents with dementia demonstrated that commercial wearables could accurately classify physical activity over a 24-hour period [14], supporting the promising potential of sensing technologies in dementia care [15,16]. However, research validating activity classification and intensity thresholds in older adults with dementia remains limited, as demonstrated in a systematic review by Gorman et al [13] exploring physical activity and sedentary behaviors in older adults, finding that there are no standardized accelerometry-based thresholds for moderate-to-vigorous or sedentary activity, with most cut-offs validated in healthy adults rather than cognitively impaired populations. Research using wrist-worn accelerometers and actigraphy in a cohort of 415 nursing home residents in Australia demonstrated that these devices could capture patterns of inactivity and sleep duration in this population. The study also highlighted practical challenges, particularly around device accuracy and participant adherence, which was particularly low (<50%), concluding that additional work is needed to refine sensor placement, device characteristics, and methodological approaches for use in a nursing home setting [7].

Sleep disturbances are prevalent in nursing home residents and affect up to 90% of those with dementia [17], with common issues including insomnia, sundowning, restless legs, and fragmented sleep. Sleep quality is particularly compromised in people with dementia residing in nursing homes [18,19], and although nonpharmacological interventions are recommended [20], psychotropic medications remain widely used and may worsen sleep or increase the risk of injury [21], contributing to further NPSs such as agitation, anxiety, and nighttime restlessness [18]. Key sleep metrics, including efficiency, latency, wakefulness after sleep onset, fragmentation, regulation, and total sleep, decline with age and are further impaired for people with dementia [22]. Autonomic regulation of sleep also changes with age and neurodegeneration, particularly regarding parasympathetic nervous system involvement in the dampening of the sympathetic nervous system during deep sleep [23]. Sleep durations of 6 to 9 hours have been associated with improved parasympathetic function in older adults with neurodegenerative disease [24].

Polysomnography (PSG) remains the gold standard for sleep assessment but is often impractical and burdensome for people with dementia in nursing homes [25]. Consumer wearables provide sleep estimates using accelerometry and photoplethysmography, but they frequently overestimate sleep in individuals with sleep dysfunction [26] and vary in accuracy [27]. Newer commercial wearable models offer sleep staging, and although sleep sensitivity tends to be adequate, the poor detection of awake periods reduces accuracy, making these devices not yet adequate for research or clinical standards and not validated in an older adult population [28]. Radar-based systems [29] offer a contact-free alternative capable of monitoring sleep in free-living environments. These systems produce digital biomarkers comparable to PSG and show promising accuracy [30], though further research is needed to confirm their reliability and clinical use for longitudinal monitoring in real-world dementia care settings.

Study Aim and Objectives

This study aims to explore the long-term capabilities of multimodal sensing technologies for assessing physical activity levels and sleep quality using selected digital biomarkers for nursing home residents with dementia. Objectives were for observation to be aligned with real-world conditions in which such sensing technologies would be applied within a nursing home environment, and to assess whether distinct differences in selected digital biomarkers can be observed accurately and reliably longitudinally.

Methods

Design and Setting

This study is related to an observational pilot study: digital phenotyping for changes in activity at the end of life in people with dementia (DIPH.DEM): an observational trial based on sensing technology. DIPH.DEM is a cornerstone study for a larger observational study titled “Decoding Death and Dying in People With Dementia by Digital Thanotyping” (5-D; REK 657596, NEM 2023/166). DIPH.DEM was designed to improve the overall quality, recruitment strategies, and efficacy of the larger 5-D study. This paper is an extension of a previous article [31], which used the DIPH.DEM baseline data (description in Table 1) to investigate the association between daytime activity and sleep quality in people with dementia residing in a nursing home. The DIPH.DEM cohort and study design have previously been described in detail in 2 previous articles [31,32].

Participants (n=11) 65 years or older were recruited from 2 dementia wards in a Norwegian nursing home. Eligibility for the study included that the participants had lived in the nursing home for more than 6 weeks and had a previous diagnosis of

XSL•FO
RenderX

moderate-to-severe cognitive impairment or dementia, confirmed within the medical record and/or using the Clinical Dementia Rating (CDR) scale administered at baseline. Exclusion criteria included the presence of delirium at the baseline assessment and a current life expectancy of less than six weeks as suggested by the multidisciplinary nursing home team. Data were collected from February 2024 to May 2025. The proxy-rated questionnaires and continuous digital monitoring using sensing technologies, Garmin Vivoactive 5 or Garmin Venu 3 and Vital Things Somnofy, were conducted at 3 distinct time points: baseline, 6 months, and 1 year.

Table . Sample characteristics from the DIPH.DEM[a] study (N=11) [31].

Demographics of study participants	Values
Age (y), mean (SD; range) (n=11)	84.0 (6.1; 77 - 93)
Gender, n	
Female	8
Male	3
Months living in the nursing home, mean (SD; range) (n=11)	17.6 (12.5; 3 - 42)
Dementia as primary diagnosis, n	6
Alzheimer dementia, n	3
Parkinson disease, n	1
Clinical Dementia Rating score, mean (SD; range) (n=11)	2.2 (0.7; 1 - 3)
Mild, n	4
Moderate, n	5
Severe, n	2
Personal Self Maintenance Score, mean (SD; range) (n=11)	15.7 (5.7; 8 - 23)
Comorbidities (GMHR[b]), mean (SD; range) (n=11)	2.6 (0.7; 1 - 3)
Neuropsychiatric Inventory (NPI-NH[c])–12 subsections, mean (SD; range)	
Agitation (n=5)	2.2 (2.2; 1 - 6)
Delusion (n=4)	3.0 (2.4; 1 - 6)
Hallucinations (n=3)	3.0 (2.6; 1 - 6)
Depression (n=4)	2.0 (1.4; 1 - 4)
Anxiety (n=3)	1.3 (0.6; 1 - 2)
Apathy (n=4)	5.8 (4.6; 1 - 12)
Irritability (n=5)	3.6 (2.9; 1 - 8)
Euphoria (n=1)	8.0 (0.0; 8 - 8)
Disinhibition (n=4)	1.5 (0.6; 1 - 2)
Aberrant motor behavior (n=4)	1.0 (0.0; 1 - 1)
Nighttime behavior disturbances (n=6)	4.7 (2.9; 1 - 8)
Appetite or eating (n=4)	4.0 (2.9; 1 - 8)
Total medication use, mean (SD; range) (n=11)	7.6 (3.4; 2 - 13)
Psychotropic drug use, mean (SD; range) (n=8)	1.9 (1.4; 1 - 5)

[a]DIPH.DEM: digital phenotyping for changes in activity at the end of life in people with dementia.

[b]GMHR: General Medical Health Rating.

[c]NPI-NH: Neuropsychiatric Inventory-Nursing Home.

Ethical Considerations

Verbal and written informed consent were obtained in direct conversation with the residents who demonstrated sufficient capacity to consent. For those lacking this ability, we obtained consent from the resident's legal guardian, usually a family member, after explaining the aims and protocol of the study. The DIPH.DEM study was approved by the Regional Committee for Medical and Health Research Ethics (REK) in Norway in October 2023 (approval number 634938).

XSL•FO
RenderX

Traditional Questionnaires

Traditional outcome measures used in this study were the Neuropsychiatric Inventory–Nursing Home version (NPI-NH) [33], assessing symptoms of sleep disturbance (Nighttime Behaviours section K), and the Physical Self Maintenance Scale (PSMS) [34], assessing functional activity levels and adverse effects of inactivity. The NPI-NH (section K) [35] includes questions about difficulty falling asleep, frequent nightly awakenings, wandering, dressing in the middle of the night, and waking earlier than normal to begin the day. The PSMS [36] includes functional activities of ambulation, bathing, grooming, dressing, toileting, and feeding. To define the severity and level of disturbances within this study, we chose to use a global scoring system from 6 to 30 (6 questions and 5 possible answers), with lower scores indicating lower dependency and higher scores indicating higher dependency.

Additional baseline measurements reported in this study were the General Medical Health Rating (GMHR) [37] for the assessment of general health and comorbidities, 4AT (Assessment Test for delirium) [38], and the CDR [39]. The CDR questionnaire (range 0 - 3) is a widely accepted global scale developed to clinically identify the presence of dementia and stage its severity (score of >0.5: cognitive impairment/likely dementia; 1: mild; 2: moderate; 3: severe dementia). Within our study, participants were included in the study with a score equal to or greater than 1 on the CDR. The GMHR (range 1 - 4) assesses the number and impact of comorbidities (1=very good; 2=good; 3=moderate, and 4=bad health). The 4AT Test (range 0 - 12) is a screening tool for delirium and consists of 4 questions evaluating alertness, cognitive function, and acute change, with a score of 4 or above indicating potential delirium. All traditional questionnaires used were previously validated and provided in the Norwegian language.

Sensing Technologies and Digital Biomarkers

The sensing technologies used in the study were Somnofy (Vital Things AS, Trondheim, Norway) [40] version 0.7 with sleep algorithm 1.0 and Garmin (Garmin Ltd., Switzerland) Vivoactive5 smartwatch [26] firmware version 11.14 or Garmin Venu 3 smartwatch (X) firmware version 12.11. Digital biomarkers used in this study were acceleration-based physical activity estimates using ENMO, sleep efficiency (SE), wake after sleep onset (WASO), sleep regulatory index (SRI), total sleep time (TST), sleep fragmentation index (SFI), and no presence (time out of bed) (Table 1). Garmin Vivoactive5 was used for data collection at baseline and 6 months and upgraded to Garmin Venu3 at the 1-year time point for improved battery capacity and data storage capabilities. Both smartwatch models contained accelerometers used to capture raw acceleration signals. The Venu3 includes additional sensors, a barometric altimeter, gyroscope, and the updated Elevate V5 heart-rate sensor, while the earlier model uses the V4 sensor. Only accelerometer-derived raw data were analyzed in this study. Participants wore the device continuously for 7 days at each data collection point (baseline, 6 months, 1 year), including during sleep and bathing.

Garmin wearables, including Vivoactive and Venu models, demonstrate acceptable validity and strong interdevice reliability for step counting and movement assessment in laboratory and free-living settings [41,42]. Prior studies report accurate step detection across walking speeds and age groups, including older adults with slower gait patterns [43,44]. Garmin devices have also shown reliable estimation of physical activity using raw acceleration data [45], and ENMO-based thresholds applied to wrist-worn Garmin sensors provide high sensitivity and specificity for distinguishing sedentary and light-intensity behaviors [46].

Data Extraction and Preprocessing

Physical Activity Levels: Euclidean Norm Minus One—Acceleration Data

Raw data parameters for the smartwatches were synced, paired, and retrieved using a hub through Fitrockr [47], a data broker based in Berlin, Germany, and acceleration was collected at 25 Hz. The extracted data were imported and converted in MATLAB and STATA-compatible types. Based on the Unix time timestamps to Unix time, the data were segmented into 14-hour periods (07:00:00 AM-08:59:59 PM) representing daytime; the first and last partial days were excluded to only consider full day recordings (24 h), resulting in 5 days and 6 nights of total acceleration data per participant. Nighttime physical activity was considered within the remaining timeframe of 09:00:00 PM-06:59:59 AM and based on nightly routines at the nursing home. The raw acceleration data were converted to the universal metric ENMO for physical activity analysis. ENMO is the vector magnitude of the 3 raw signals (x, y, z) minus 1. One-minute periods were used during daytime (07:00:00 AM-08:59:59 PM), nighttime (09:00:00 PM-06:59:59 AM), and daily 24-hour (07:00:00 AM-06:59:59 AM) measurements (mean, median, SD). The thresholds for physical activity levels using ENMO classifications were determined according to previous literature [46] and included sedentary activity to time (<18 milli-g), light physical activity (18 - 22 milli-g), light-to-moderate activity (>22 - 60 milli-g), and moderate-to-vigorous physical activity (MVPA; >60 milli-g). The calculation used for conversion of raw accelerometry data to ENMO (units: milli-g) was as follows:

$$ENMOi=x(t)i2+y(t)i2+ z(t)i2 -1000$$

Digital Sleep Biomarkers

Sleep metrics (SE, SRI, WASO, time in no-presence, and SFI) were exported directly from the Somnofy platform. All Somnofy sleep data were manually reviewed to remove daytime sleep episodes occurring between 07:00 AM and 08:59 PM. These daytime events were documented separately to avoid influencing nighttime sleep estimates. Daytime sleep is not reported here, as the radar system only detects sleep occurring within its sensing range (ie, in bed) and therefore does not holistically capture daytime sleep, which may occur elsewhere than the bed. The nighttime window was selected to align with the routine administration of psychotropic medications for sleep disturbance (typically around 09:00 PM) and standard bedtime procedures at the nursing home. Participants were excluded if fewer than 10 hours of nighttime sleep data (one full night) were not available.

XSL•FO
RenderX

SE was calculated as the proportion of total sleep time relative to time in bed, expressed as a percentage from 0 to 100. SRI, also provided by Somnofy, reflects the consistency of sleep-wake patterns across days and requires at least 4 consecutive nights of data; values are expressed as a percentage and range from 0 to 100. WASO represents the cumulative minutes awake after initial sleep onset. The SFI score quantifies sleep fragmentation as the number of transitions from deep to light sleep per hour of sleep and is expressed as a percentage from 0 to 100. Somnofy additionally reports time in "no presence," defined here as time or minutes spent outside the sensor's effective range (>3 m), which was interpreted as time out of bed during the nighttime period. All wake periods overlapping with "no presence" were manually checked to confirm accuracy.

Statistical Analysis

Descriptive statistics and narrative synthesis are provided including mean, median, minimum, maximum, and SD for all relative variables. The data were tested for normality and analyzed using MATLAB R2023a and STATA SE18.5; outliers were detected using box plots. The data were dependent, nonparametric, and not normally distributed resulting in the use of the Friedman test to assess differences between the 3 data collection time points. The Friedman test is used for one-way repeated measures ANOVA by ranks. A post hoc evaluation of the specific differences between the time points in which the null hypothesis was rejected was performed using the Wilcoxon signed-rank test. Kendall *W* interpretation of effect is as follows: 0.1 - 0.29 small effect size, 0.3 - 0.5 moderate effect size, and >0.5 large effect size. A sensitivity analysis was performed as a subanalysis of the significant results by removing influential extreme outliers, which were defined as totals beyond 1.5 times the IQR. The results were considered statistically significant at a $P<.05$, and at a χ^2 (2 *df*) critical value of ≥5.991. Reliability as temporal stability is reported using an intraclass correlation coefficient (ICC 1,1 and ICC 3,1) defined with scores ranging from 0 to 1 and score interpretation: <0.5 as poor agreement, 0.5 to <0.75 as moderate agreement, 0.75 to <0.90 as good agreement, and 0.9 to 1.0 as excellent agreement.

Results

Eleven participants were recruited from February 2024 to May 2025. Two participants passed away during the data collection period, resulting in final analysis of 9 participants. Data were missing for the following reasons: charging of the smartwatch (1 - 2 hours on day 4) and periodic nonadherence from the participants (removal of the smartwatch for periods ≤2 hours). Adherence was defined as the total wear time (Garmin VivoActive5 or Venu3) calculated after the initial data extraction of the first and last day, and was 96% at baseline, 88% at 6 months, and 94% at 1 year. For the acceleration data, after the removal of partial days within the available data profiles (first and last day), there were a total of 135 acquisition periods available for the final analysis. Additionally, a total of 189 data acquisition periods, consisting of data from a total of 219 nights, were used for analysis of the sleep quality digital variables.

Participant characteristics and demographics at baseline for the DIPH.DEM study (n=11) can be found in Table 1. Participants were mostly female (8/11), age ranging from 77 to 93, living in the nursing home for a mean of 17.6 (SD 12.5) months, and with an average score of 2.2 on the CDR indicating a moderate level of dementia. Participants had a mean score of 2.6 (SD 0.7) on the GMHR, suggesting a moderate level of comorbidities consisting of greater than or equal to 3 chronic illnesses and concomitant medication use. Chronic diagnoses within the group included Alzheimer disease, Parkinson disease, diabetes, and heart disease. At baseline, assessed by the NPI-NH (section K for nighttime behavior), almost half (6/11) of the group was classified as having nighttime sleep behaviors defined within the study as frequent nighttime activity and awakenings. Total daily polypharmacy within the group ranged between 2 and 13 total medications per person, and the use of daily psychotropics due to sleep disturbances within the group profile ranged from 1 to 5 prescriptions per participant, per night.

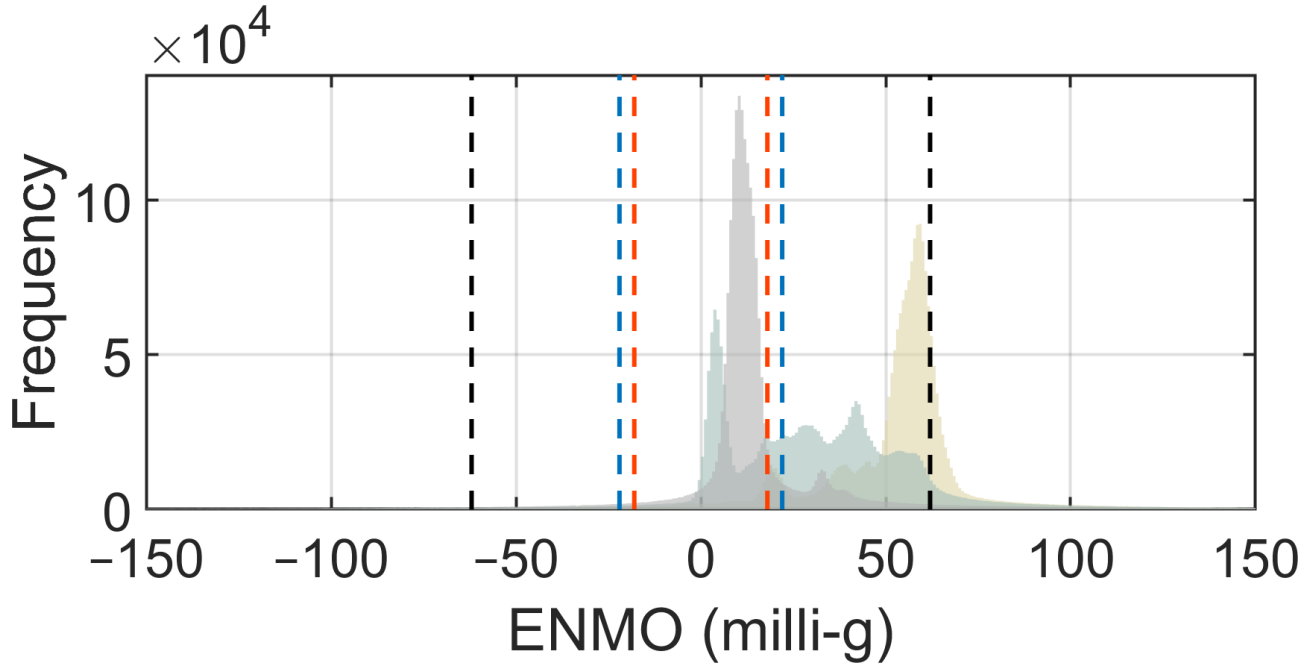
There were longitudinal differences in nighttime physical activity levels from baseline to 1 year ($P=.01$), with a declining trend (33% decrease from baseline to 1 year) in all ENMO means, most pronounced from 6 months to the 1-year time points (Figures 1-3). The majority of the group's 24-hour activity intensities, as illustrated in Figure 1, were either sedentary threshold or below (<18 milli-g) or between sedentary time and light-to-moderate physical activity thresholds (18 - 60 milli-g). In Figure 2, we observe a loss of day or nighttime rhythm or flattening of ENMO intensities, most distinct at the 1-year time point, indicating that daytime ENMO more closely resembled the nighttime ENMO intensities at the 1-year time point. The temporal stability (ICC) within and between individuals over time was poor (0.00 - 0.02; Table 2), suggesting that the acceleration data (ENMO) was not a reliable measurement longitudinally; however, variance between-persons at a single time point ranged from moderate to good (0.58 - 0.79), suggesting that ENMO can distinguish between individuals cross-sectionally in a stable and meaningful way. After removing outliers and aggregating repeated measurements, there was no statistically significant change in nighttime ENMO across time points; however, the effect size remained moderate, indicating a meaningful degree of within-participant change over time.

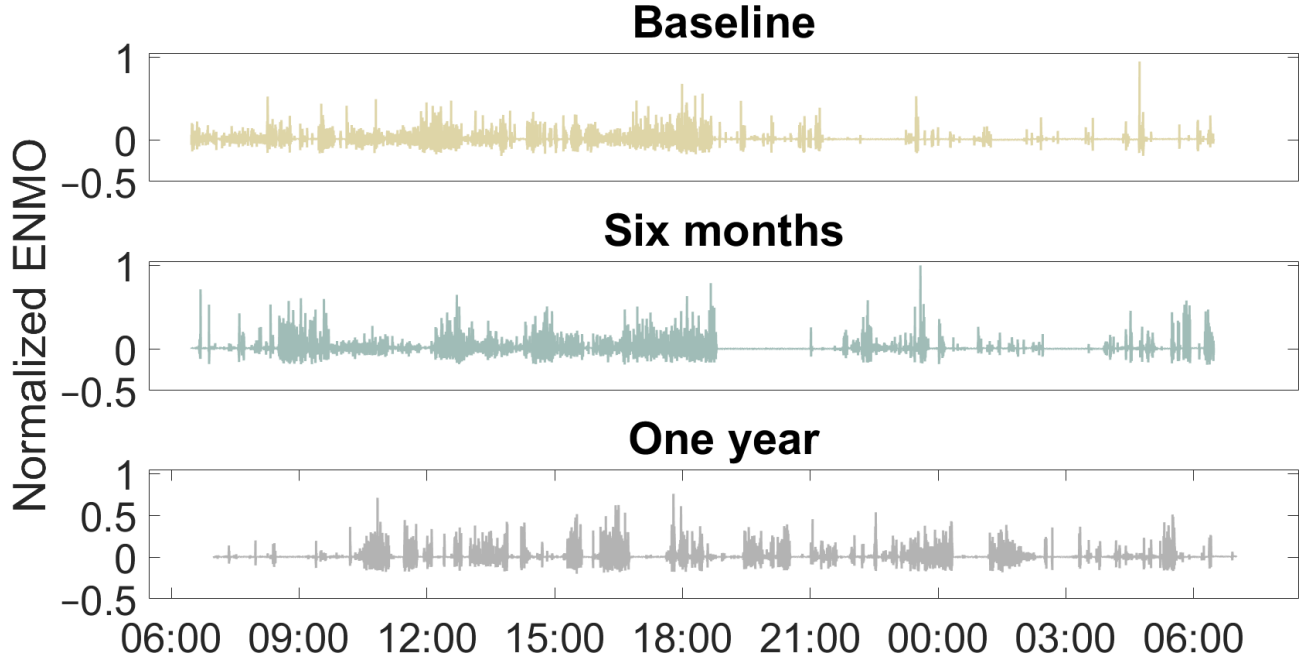
Four of the digital sleep quality biomarkers were found to have differences from baseline to 1 year: TST ($P=.02$), SE ($P=.02$), WASO ($P=.01$), and SRI ($P=.01$; Table 2, Figures 4 and 5). This suggests that these sleep quality digital biomarkers are sensitive enough over time to be used as a tool for identifying discrete changes in sleep quality. Temporal stability (ICC) of the sleep digital biomarkers over time was moderate to strong (0.54 - 0.92; Table 2), with the most reliable longitudinal metrics being SE (0.92) and WASO (0.78). This indicates that these sleep biomarkers, derived from the Somnofy radar-based sensors, provided clinically meaningful data over time with minimal residual variance. A sensitivity analysis was performed for subanalysis of TST, SE, WASO, and SRI. After the removal of extreme outliers, SE and SRI showed no significant changes over time but moderate within-participant effect sizes. Both

XSL•FO
RenderX

WASO and TST demonstrated longitudinal change, each with large effect sizes indicating substantial within-participant shifts.

Figure 1. Distribution of 24-hour physical activity levels (Euclidean norm minus one [ENMO]) for one participant at baseline (yellow), 6 months (green), and 1 year (gray). Explanation of thresholds is as follows: space between orange lines=sedentary time (<18 milli-g), between red and blue lines=light physical activity (18 - 22 milli-g), between blue and black lines=light-to-moderate physical activity (>22 - 60 milli-g), all else from black lines=moderate-to-vigorous activity (>60 milli-g).





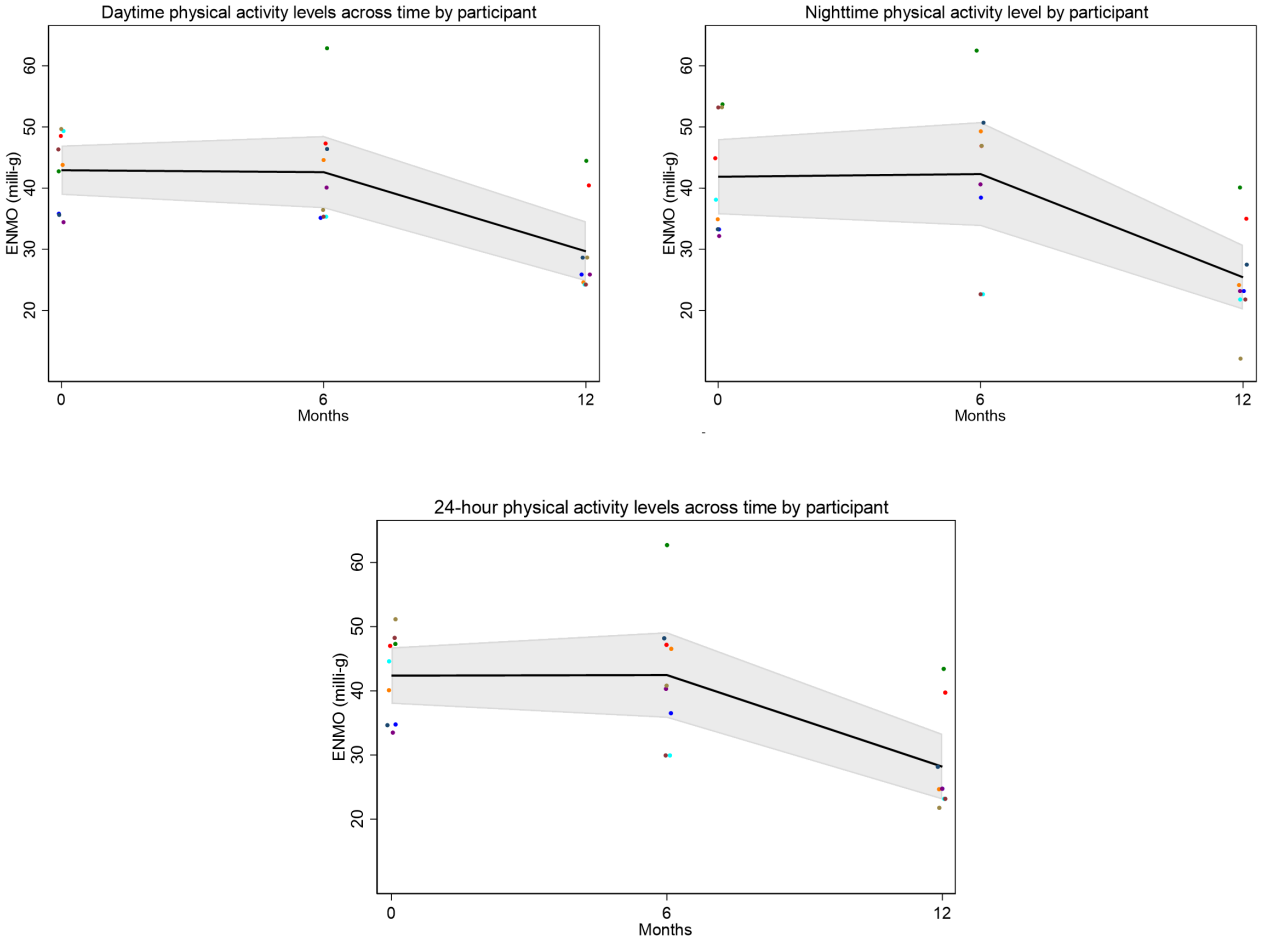


Figure 2. A 24-hour physical activity level. Definition of normalized Euclidean norm minus one (ENMO): the EMNO values were divided by the maximum value of the 3 days represented and are a snapshot for the same participant (Figure 1) at baseline, 6 months, and 1 year.

Discussion

Principal Findings

This study aimed to explore the use of sensing technologies in the assessment of longitudinal changes in physical activity levels and sleep quality in people with dementia living in a nursing home. We found that nighttime physical activity levels (ENMO) and 4 distinct digital sleep biomarkers (TST, SE, WASO, SRI) showed discrete changes across the 1-year data collection period, suggesting that these selected digital biomarkers could detect modest variations and declines in activity and sleep quality over time. Temporal stability of the sleep metrics was moderate to excellent; however, further inspection of the reliability of all longitudinal ENMO measured physical activity level data was poor. This suggests that the acceleration metric was unreliable as a longitudinal assessment tool and would be best applied to a single time-point, where reliability remained moderate to good or that for real-life use, additional sensor modalities and positions are required for better quality data. Adherence and acceptability of the selected technologies remained high across the 1-year period, with no adverse events, suggesting that the chosen devices and level of unobtrusiveness were a good match for the cohort. This study's findings are important in the illustration of the capabilities and limitations of sensing technologies and their corresponding digital biomarkers as clinical decision-making tools for people with dementia. It also demonstrates the trade-off between the level of unobtrusiveness and quality of data when choosing sensing technologies for use within more vulnerable groups.

The standardization and clarification of measurement context for digital biomarkers is needed, as emphasized in a recent meta-analysis [48] stating that accelerometry is increasingly being used to quantify physical activity, yet daily activity metrics produced using acceleration data remain heterogeneous and primarily reflect overall movement rather than specific health-related exertion. In our study, ENMO-derived activity levels distinguished long-term group differences; however, the longitudinal reliability of these measures was poor. This is consistent with previous work [49,50] stating that the most accurate results and models occur with thigh or low back placement of sensors for the monitoring of physical activity in older adults. Therefore, device placement and user burden are central considerations; in this study's nursing home population, a wrist-worn device was selected to minimize obtrusiveness and encourage adherence for older, potentially frail residents. While wrist-based wearables may be appropriate for single time point assessments, long-term monitoring may require alternative placements, such as the hip or low back, or integration with additional sensor modalities, to improve long-term reliability.

The World Health Organization (WHO) published the Global Action Plan on Physical Activity (GAPPA) [51,52], providing policy guidance for increased activity levels, reduced sedentary behavior, and tailored interventions across age groups. The report highlights limitations of self- and proxy-reported measures and advocates integrating wearable technologies into global physical activity surveillance. It also calls for standardized protocols to examine dose-response relationships between activity, sedentary behavior, and health outcomes, and for future research that enables data triangulation, refined estimates of total activity volume, and the identification of age-

XSL•FO
RenderX

and disease-specific associations [53]. This is a promising step toward future global clinical use and recommendations for standardized metrics of accelerometry-based data; however, focused research on more vulnerable groups, such as people with dementia, is still lacking.

The landscape of sleep-monitoring technologies for individuals with dementia has evolved rapidly, integrating passive and wearable systems tailored for long-term care and home use. Traditional actigraphy remains widely used to assess sleep-wake patterns and circadian disruptions in people with dementia [48]; recently, more advanced noncontact sensors, such as under-mattress sleep mats leveraging ballistocardiograph and respiration monitoring, and radar technology, are being deployed to track heart rate, breathing, movement, and fragmentation of sleep, reducing the need for wearable devices [27,30]. Due to the rapid development of new sensing technologies that rival gold standard PSG, a recent study emphasized the importance of the evaluation of novel sleep technologies conducted within longitudinal, real-world settings including people with advanced dementia, as a pathway for future device validation [30]. These recommendations reflect a shift toward more nuanced, long-term, and minimally burdensome monitoring modalities that are critical for capturing sleep changes in nursing-home and real-world settings, while addressing the unique compliance challenges of dementia care.

The fundamental differences between traditional proxy-rated questionnaires and digital biomarkers derived from sensing technologies may capture distinct phenomena and often yield divergent conclusions [54]. The NPI-NH and PSMS are established proxy-rated instruments commonly used in nursing home research to assess behavioral symptoms, functional ability, and sleep-related disturbances. However, these questionnaires do not capture the same dimensions of sleep quality represented by the digital measures used in this study. Differences in data capture frequency also limit comparability and validation between digital and traditional tools, as traditional questionnaires are typically completed every 30 to 90 days, while sensing technologies generate continuous, real-time data. Because proxy-rated tools and sensor-based measures assess different constructs and operate across different temporal scales, they are not directly interchangeable. Future research should incorporate assessment instruments that more closely correspond to digital sleep and activity metrics to strengthen construct validity and improve clinical interpretation. We cannot, therefore, conclude that sensing technologies provide superior assessments; rather, they can offer a unique definition of physical activity levels and sleep patterns through digital biomarkers, which can strengthen and fill in the blanks between periodic traditional proxy-rated assessments.

Due to rapid development and consequential obsolescence, the future validation of sensing technologies should involve repeated measures within the same modality to accelerate validation and contextualize digital biomarker results within target populations, such as people with dementia. Global consensus on the use of a standardized metric for accelerometry data and clinical translation of the corresponding thresholds should be prioritized to improve the generalization and applicability of results in real-world settings. Establishing population and context-specific thresholds, which account for age, health status, cultural, and environmental factors, will be essential to improving generalizability, applicability, and interpretability in future studies. Until these challenges are appropriately addressed, integrating proxy-rated assessments, inclusion of human-in-the-loop interpretation for data, and cautious interpretation of digital biomarkers is most appropriate for vulnerable populations such as people with dementia residing in nursing homes.

Although this study demonstrates the use of sensing technologies and digital biomarkers, it is not without limitations. The sample size, though appropriate for a pilot study design, is small, and the results should therefore be interpreted with caution. A sensitivity analysis was conducted to account for the small sample size, the influence of extreme values, and to clarify which effects were most robust. After removing outliers and aggregating repeated measurements, the overall pattern of change remained consistent with the original results, but only WASO and TST retained statistical significance, indicating that these domains showed the strongest and most reliable longitudinal shifts. Clinically, this suggests that while participants exhibited meaningful variability across physical activity metrics and multiple sleep parameters, the most stable and reproducible changes over time occurred in wakefulness and sleep duration, whereas other measures may require larger samples to detect effects with greater confidence. Regardless, further investigation is warranted based on these preliminary results. Further, this study uses the universal metric ENMO to interpret the acceleration data into physical activity levels; however, there is currently no standardized metric established for clinical translation of physical activity digital biomarkers, and another method could produce varied results. This study's objective was not to validate specific sensing technologies, and we would like to note that the nature of rapidly developing technologies creates a challenge for the timely validation of these novel devices and a gap between the use of these devices and digital biomarkers in research versus real-world applications.

Conclusions

Sensing technologies are promising for supporting more objective, data-driven care models in nursing homes. Acceleration-based metrics from wrist-worn devices appear most robust for cross-sectional assessment, whereas contactless radar-derived sleep biomarkers demonstrate stronger suitability and accuracy for both snapshot and longitudinal monitoring. Our findings underscore the need for cautious, context-aware interpretation of digital biomarkers. Further work is required to establish the accuracy and reliability of these sensing methods before they are incorporated into clinical decision-making frameworks.

Acknowledgments

We first need to thank the participants, their loved ones, and nursing home team for their invaluable contributions to this study. We would also like to thank Helse Vest and our partners at Neuro-SysMed and Haraldsplass Deaconess Hospital for their continued support of the project.

Grammarly was used to suggest language improvements in the manuscript.

Funding

Funding was provided by the Western Norway Regional Health Authority (Helse Vest RHF; sponsor protocol code: F-12829-D10484).

Data Availability

All data supporting the results and conclusions of this article will be made available by the authors, without undue reservation.

Authors' Contributions

All authors (LDB, MP, OMS, KH, BSH, BM) contributed to the study conception and design. LDB contributed to the initial writing of the manuscript. LDB and BM performed all data processing and analysis. All authors read, assisted with further editing, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Digital interventions can support sodium restriction in chronic kidney disease; yet, implementation and engagement barriers remain poorly understood.

Objective: This mixed methods study evaluated a nurse-led digital program for sodium restriction, focusing on 3 key aspects: implementation, engagement, and patient experience.

Methods: This study was initially designed as a randomized controlled trial but was revised to a mixed methods implementation study due to high rates of missing primary outcome data. Quantitative measures included 24-hour urinary sodium excretion (the primary outcome of the original randomized controlled trial), knowledge tests, blood pressure measurements, and quality-of-life assessments. Concurrently, we conducted in-depth qualitative interviews with a purposive sample of participants. Quantitative and qualitative data were collected in parallel, analyzed separately, and then integrated to provide a comprehensive understanding of participants' experiences with the intervention.

Results: Among 99 enrolled patients (46 in the enhanced digital intervention group and 53 in the minimal digital control group), the program led to a significant improvement in sodium-related knowledge as a secondary exploratory outcome (P=.005). However, the 24-hour urine collection completion rate was only 24.2% (n=24), precluding reliable conclusions regarding the primary outcome. Qualitative findings revealed a "measurement paradox," in which the gold-standard assessment itself posed a major barrier to adherence. Integrated data illustrated a patient journey marked by early enthusiasm, followed by declining engagement due to digital fatigue, family resistance, and poor fit with daily life. This misalignment created a disconnect between acquired knowledge and measurable behavior change.

Conclusions: A nurse-led digital intervention was associated with modest improvements in sodium knowledge in chronic kidney disease. However, success requires reducing the monitoring burden and improving real-world fit. The "measurement paradox" highlights the need for patient-centered outcome measures. We propose a "stage-matched intervention" framework to guide adaptive digital tools. Future research should prioritize multicenter pragmatic trials to bridge the knowledge-action gap.

KEYWORDS

chronic kidney disease; sodium restriction; digital health; mixed-methods research; nurse-led digital intervention

Introduction

Chronic kidney disease (CKD) affects millions worldwide, and high sodium intake accelerates disease progression [1-3]. Clinical guidelines recommend a daily sodium intake below 2.3 grams or 100 mmol to control blood pressure and preserve kidney function [4-6], but real-world adherence remains poor. Fewer than 30% of patients with CKD meet this target [7-9], revealing a critical knowledge-practice gap in disease management. As frontline providers, nurses are well positioned to leverage digital tools to improve sodium management [10-12]. To systematically address these self-care deficits, this study was guided by Orem's Self-Care Deficit Nursing Theory, which posits that individuals require nursing support when their

XSL•FO
RenderX

self-care capabilities are insufficient [13]. For patients with CKD, inadequate knowledge, poor adherence, and low self-monitoring skills represent key self-care deficits in sodium management. The nurse-led digital intervention was therefore designed to identify these deficits, provide compensatory support, and enhance self-care agency, fully aligning with the core logic of Orem's theory. Accordingly, we developed a theory-driven, nurse-led mobile digital sodium restriction program embedded within our independently designed Su Yi app (Thinmed Medical Technology (Chongqing) Co, Ltd), integrating nursing expertise into patient education to address these self-care deficits [14,15].

While digital therapeutics have demonstrated benefits for chronic conditions such as hypertension [16-19], their application in CKD management remains nascent. Most existing studies rely on idealized randomized controlled trial (RCT) designs (Checklist 1) [7,20] that prioritize internal validity but overlook real-world implementation barriers, including digital fatigue, social resistance, and procedural burden. A prime example is the 24-hour urinary sodium test, the gold standard for estimating sodium intake, which imposes a considerable burden on patients due to its cumbersome nature [21]. Yet, its role as a primary end point is rarely reconsidered, creating a critical measurement paradox. Low adherence to such measures renders study outcomes inconclusive, hindering the identification of why interventions fail. Although some studies indicate that digital interventions can improve dietary knowledge among patients with CKD [22,23], the reasons why knowledge gains often do not translate into improved behavior or physiological outcomes remain unclear. Critically, large-scale failures in objective data collection often overshadow patients' actual experiences with digital tools, obscuring systemic mismatches between intervention design and the realities of daily life.

Existing literature identifies a key paradox in digital health interventions. Patients often show significant improvements in health-related knowledge; yet, objective behavioral metrics, such as physiological assessment completion rates, remain consistently low. In sodium management programs specifically, knowledge acquisition does not reliably translate into adherence to urine collection protocols used to verify dietary changes. This discrepancy raises a critical question: why do theoretically effective interventions struggle to sustain in real-world settings? Possible explanations include intervention design flaws, insufficient patient motivation, or a fundamental misalignment between digital tools and patients' daily experiences. The field currently lacks an in-depth understanding of the full engagement process among patients with CKD in digital sodium management. Without insights into patients' emotional shifts, practical challenges, and evolving needs during intervention, there is a risk of repeatedly developing technically advanced but clinically impractical solutions. To address this gap, advanced practice nurses and clinical nurse researchers conducted a parallel mixed methods study integrating quantitative and qualitative approaches. Led by the nursing team, the intervention was designed and implemented to systematically evaluate both the effectiveness and patient experience of a nurse-developed digital sodium restriction program for patients with CKD.

Initially registered as an RCT (ChiCTR2200060627) with 24-hour urinary sodium as the primary outcome, this study was reconceptualized as an exploratory mixed methods implementation study due to 75.7% (75/99) missing data on the primary outcome. The objectives shifted from efficacy verification to exploring implementation barriers and patient engagement experiences. Guided by Orem's Self-Care Deficit Nursing Theory, we hypothesized 2 core points. First, the nurse-led digital intervention may improve sodium-related knowledge but is likely to face high attrition in burdensome 24-hour urinary sodium collection due to mismatched self-care capabilities. Second, mapping longitudinal engagement trajectories is expected to identify the core implementation barriers, informing human-centered digital tool development and clarifying the knowledge-behavior disconnect. This study addresses a critical gap in digital nursing research by moving beyond traditional efficacy-focused RCTs to prioritize real-world implementation and user experience. Our findings offer practical guidance for designing adaptive, feasible digital interventions for CKD management.

Methods

Study Design and Setting

This study was prospectively registered as a parallel-group RCT in the Chinese Clinical Trial Registry (ChiCTR2200060627; registered on June 6, 2022). The initial design aimed to evaluate intervention efficacy, with 24-hour urinary sodium excretion as the primary outcome and secondary outcomes including sodium-related knowledge, blood pressure, and quality of life (QOL). A 3-month follow-up duration was selected based on previous digital health implementation studies in CKD and hypertension, which have demonstrated that 8 to 12 weeks is sufficient to detect changes in intermediate physiological and behavioral outcomes in real-world settings [7,17]. This time frame balances the need to observe meaningful behavior change while minimizing attrition in longitudinal implementation research.

During the 3-month interim review, only 24.2% (24/99) of participants completed valid 24-hour urine collections, resulting in 75.7% (75/99) missing data for the primary outcome, far below the prespecified acceptable threshold of 60%. Because increasing the sample size could not improve data completeness, the study design was formally revised from an RCT to a single-center, exploratory mixed methods implementation study [24-26].

This design adaptation was consistent with reporting guidelines for pragmatic implementation research. The original sample of 99 participants remained adequate for mixed methods inquiry, which typically requires at least 80 quantitative participants and 15 to 30 qualitative participants [27]. Accordingly, the analytical focus shifted from confirmatory efficacy testing to exploratory implementation outcomes. The core objective was revised to evaluate implementation processes, participant engagement experiences, and barriers to a nurse-led digital sodium restriction intervention in patients with CKD.

XSL•FO
RenderX

During the 3-month interim progress review conducted in November 2022, the completion rate for the prespecified primary outcome measurement was merely 24.2% (24/99), far below the expected level. Concurrently, notable participant attrition was observed in both groups. Given the poor feasibility of continuing the original primary outcome evaluation, our research team comprehensively assessed the actual research progress and field conditions. After obtaining formal approval from the ethics committee, we decided to abandon the planned primary outcome efficacy analysis, redefine this project as an exploratory mixed methods implementation study, and shift our core research focus to exploring intervention implementation processes and real-life patient experiences.

Ethical Considerations

The research design and study protocol were approved by the Ethics Committee of the Second Affiliated Hospital of Army Medical University (approval number 2022-Research-040-01). The revised study design was subsequently reviewed and approved by the same ethics committee (approval number 2022-Research-515-01). All participants provided written informed consent prior to enrollment. All study procedures were conducted in accordance with the Declaration of Helsinki.

Participant Recruitment and Screening

Eligible participants were recruited and screened by trained clinical nurses from inpatients admitted to the nephrology department between June 2022 and August 2022. Inclusion criteria were as follows: age 18 to 65 years; diagnosis of CKD stages 1‐5 [28], including those with hypertension; an estimated glomerular filtration rate stable over the past 3 months; 24-hour urinary sodium excretion >130 mmol/day at baseline; Barthel Index score ≥60; Mini-Mental State Examination (MMSE) score ≥24; proficiency in using smartphones and mobile applications; and willingness to participate. Exclusion criteria included the following: recent acute kidney injury; receipt of renal replacement therapy; major cardiovascular event within 6 months; uncontrolled hypertension (systolic blood pressure >160 mm Hg or diastolic blood pressure >100 mm Hg); prior participation in similar digital health programs; or any condition likely to interfere with study compliance.

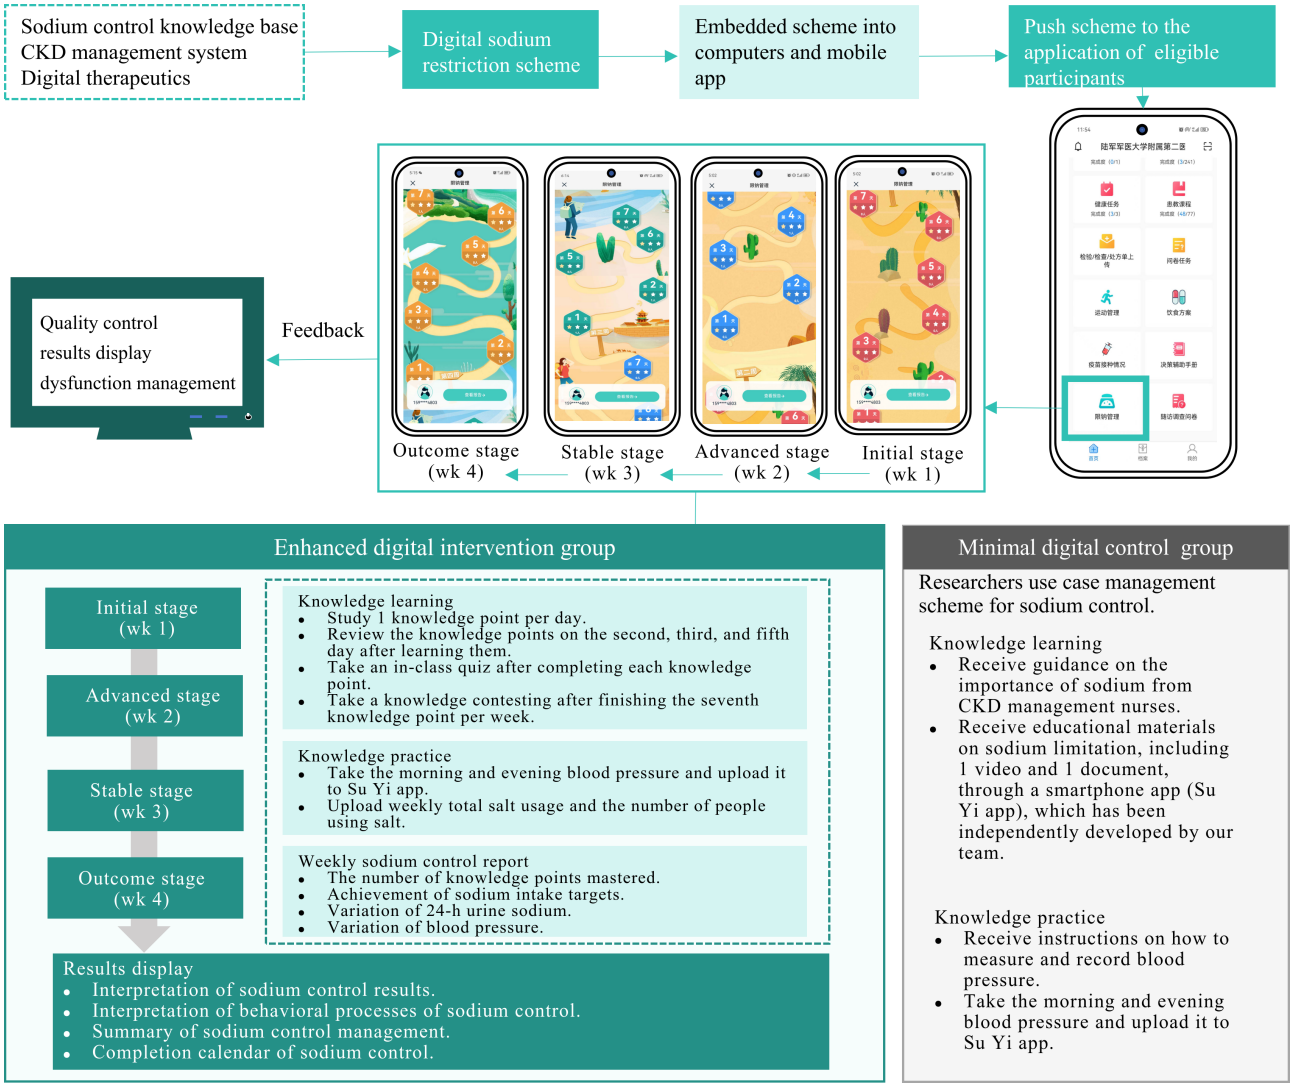
Randomization and Blinding

Eligible participants were randomly assigned (1:1) to either the intervention or control group using computer-generated random sequences in SPSS (version 24.0; IBM Corp). Allocation was concealed via sequentially numbered, opaque, and sealed envelopes prepared by an independent statistician. Due to the nature of the intervention, participants and the intervention delivery nurse could not be blinded. However, to minimize ascertainment bias, outcome assessors, laboratory technicians, and data analysts remained blinded to group allocation throughout the study. The 46:53 group size discrepancy resulted from random fluctuation of the computer-generated sequence with no manual modification. Such a degree of imbalance falls within the expected range of chance variation in simple randomization and does not compromise the validity of random allocation.

Interventions

Control Group (Minimal Digital Intervention)

Participants received minimal digital intervention [29], which included a single educational session on sodium restriction and access to the Su Yi app—a self-developed mobile platform providing static educational content (1 video and 1 text document) [30]. They were prompted daily via the app to measure and log their morning blood pressure. Both groups used the Su Yi app; however, the intervention content and intensity differed between the groups.



Intervention Group (Enhanced Digital Intervention)

Participants received an enhanced digital intervention that was strictly grounded in Orem's Self-Care Deficit Nursing Theory. The intervention followed three core theoretical components: (1) deficit identification through baseline knowledge assessment, (2) compensatory nursing support via structured education and gamified learning, and (3) self-care agency enhancement using personalized feedback and autonomous practice. The 4-week intervention was delivered in four progressive stages (Figure 1): (1) initiation (knowledge learning), (2) advancement (quizzes and peer competition), (3) stabilization (behavioral practice), and (4) outcome (personalized reporting). This staged structure directly operationalized Orem's theoretical logic of identifying deficits, providing compensatory support, and promoting self-care capacity. Gamified modules, in-app quizzes, peer competition, and standardized behavioral tasks were integrated to enhance engagement. Upon completion of the 4-week intervention, each participant received a personalized report illustrating knowledge mastery, salt intake goal achievement, trends in 24-hour urinary sodium excretion, and blood pressure trajectories. All activities were completed autonomously via the app, minimizing clinical burden while maintaining consistent nursing oversight through remote monitoring.

Both groups attended a follow-up visit 3 months post intervention for outcome assessment.

XSL•FO
RenderX

Figure 1. Formation and application process of the digital sodium control system. CKD: chronic kidney disease.

Sample Size Calculation

The sample size was calculated using PASS (version 15.0; IBM Corp) software based on the anticipated between-group difference in 24-hour urinary sodium excretion at the 3-month follow-up. Data from a previous randomized trial suggested a mean excretion of approximately 173.5 mmol/day in control groups and 147.5 mmol/day in intervention groups, indicating a potential difference of 26 mmol/day [31]. A common SD of 34.0 mmol/day was assumed based on the same study. Using a 2-sample, 2-tailed *t* test with α=.05% and 90% power, 37 participants per group were required. Accounting for an estimated 20% dropout rate, the final target sample size was set at 47 per group (total n=94).

Data Collection Procedures

Quantitative data were collected at baseline (T0) and at the 3-month follow-up (T1). Outcomes of interest included 24-hour urinary sodium excretion [32] and blood pressure [33] as potential indicators of physiological response. Blood pressure was defined as the average of 3 consecutive office blood pressure measurements. Additional outcomes comprised sodium control knowledge, QOL, and laboratory parameters. Sodium control knowledge was assessed using a 10-item questionnaire developed by the research team. The questionnaire was based on CKD sodium restriction guidelines, refined through 3 rounds of expert review, with a content validity index of 0.92, and validated via pilot testing with 20 participants and a Cronbach α of 0.78, and the questionnaire is provided in Multimedia Appendix 1. QOL was measured using KDQOL-SF (Kidney Disease Quality of Life-Short Form) 1.3 [34], and laboratory parameters included serum creatinine, urea, uric acid, electrolytes, hemoglobin, and albumin. Adherence to 24-hour urine collection was anticipated to present challenges; therefore, this measure was analyzed exploratorily and interpreted cautiously, with due consideration of completion rates.

Qualitative data were collected through semistructured in-depth interviews with a purposive subsample of 23 participants. Participants who discontinued the intervention were not included due to practical constraints related to time and research resources. This subsample comprised only intervention completers; accordingly, all qualitative findings were limited to participants who completed the full intervention program.

All interviews were conducted in Mandarin Chinese by 2 nurse researchers with master's degrees who had received systematic training in qualitative research (Checklist 2). These researchers were not involved in intervention delivery to minimize potential

XSL•FO
RenderX

bias. Face-to-face interviews were conducted in the outpatient CKD management clinic, with each session lasting 20 to 40 minutes. All interviews were audio-recorded, transcribed verbatim, and anonymized. The transcripts were then translated into English using dual translation and back-translation to ensure linguistic and conceptual fidelity. Regular debriefing sessions were held throughout data collection to enhance reflexivity and analytic rigor. The interview guide was developed under the core framework of Orem's Self-Care Deficit Nursing Theory, with the integration of key concepts from Empowerment Theory. The guide was designed to explore participants' experiences across multiple dimensions, including task execution, emotional responses, barriers encountered, and evolving needs. Thematic analysis was used to analyze the interview transcripts. To ensure coding reliability, 2 researchers independently coded 20% of the data, yielding strong intercoder agreement with a Cohen κ value of 0.72. Discrepancies were resolved through consensus discussion. The finalized codebook, which included code definitions, thematic hierarchies, representative quotes, and decision rules, was then applied to the full dataset by the primary researcher. The codebook is provided in Multimedia Appendix 2. Sensitivity analyses were conducted to assess the potential influence of selection bias on qualitative interpretations. We hypothesized that participants who discontinued the intervention may hold distinct perspectives related to higher intervention burden, digital fatigue, and competing time demands. Such systematic differences may lead to overestimation of participant engagement and underestimation of real-world implementation barriers if noncompleters are excluded from analysis.

Statistical and Analytical Approaches

Quantitative Analysis

During manuscript revision, we consulted a biostatistician regarding the handling of the substantial missing data in 24-hour urinary sodium excretion. It was determined that traditional inferential statistics (eg, *t* tests, ANOVA) would yield unreliable estimates due to severe attrition (75/99, 75.8% missing) and potential selection bias. Consequently, we have revised the manuscript to reflect a mixed methods evaluation framework, removed causal interpretations of urinary sodium outcomes, and focused the discussion on implementation insights and patient-reported experiences.

Continuous variables were tested for normality using the Shapiro-Wilk test. Normally distributed data were presented as mean (SD) and compared using independent samples *t* tests. Nonnormally distributed variables were reported as median (IQR) and analyzed using Mann-Whitney *U* tests. Categorical variables were expressed as frequencies (%) and compared using chi-square or Fisher exact tests. Intention-to-treat (ITT) analysis was applied to all primary outcomes. Statistical significance was set at $P<.05$. Analyses were performed using SAS software (version 9.4; SAS Institute Inc). Given the substantial missingness in 24-hour urinary sodium excretion (>60%), we carefully evaluated the data quality and implemented the following handling strategies: (1) ITT analysis was applied to all available data to maintain the randomized design's integrity; (2) between-group inferential comparisons were not performed, even for completers, due to the high risk of selection bias; and (3) multiple imputation was not adopted as it would require untestable assumptions about the missing values, for example, missing at random, given the extreme missing rate. We interpret this outcome exploratorily, focusing on implementation insights rather than efficacy conclusions.

Qualitative Analysis

Transcripts were analyzed using thematic analysis guided by Empowerment Theory. A hybrid deductive-inductive approach was used: initial coding was informed by predefined domains (tasks, emotions, pain points, and needs), while emergent themes were iteratively refined. Two researchers independently coded 20% of the transcripts to assess reliability, achieving consensus through discussion. NVivo 12 (QSR International) was used for data management.

Integration of Mixed Methods

A convergent parallel mixed methods design was used in accordance with the GRAMMS (Good Reporting of A Mixed Methods Study) guidelines (Checklist 3) [35]. Quantitative and qualitative data were collected in parallel, analyzed independently, and subsequently integrated using a joint display matrix. Quantitative outcomes provided the primary analytical framework, while qualitative findings were used to explain, supplement, and contextualize the quantitative results. To ensure integration rigor, 2 researchers conducted independent interpretive integration; discrepancies were resolved through consensus discussions, and a third researcher reviewed the entire integration process.

Results

Participant Flow

Of 303 screened patients, 99 were randomized: 46 to the enhanced digital intervention group and 53 to the minimal digital control group. Baseline characteristics were similar between groups (Table 1), confirming balanced randomization. At the 3-month follow-up, 52 (98.1%) in the control group and 45 (97.8%) in the intervention group completed blood pressure and blood component analysis, with the exception of 1 death in the intervention group and 1 withdrawal in the control group for personal reasons. However, only 13 (24.5%) in the control group and 11 (23.9%) in the intervention group completed the 24-hour urine collection (Figure 2), resulting in an overall completion rate of 24.2% (24/99) for this outcome measure.

Figure 2. Flow diagram of participant enrollment. KDQOL-SF: Kidney Disease Quality of Life-Short Form.

Baseline Characteristics

Baseline demographic and clinical characteristics were balanced between groups (Table 1). The median age was 48 (IQR 37 - 54) years in the control group and 44 (IQR 31-52) years in the intervention group (*P*=.21). There were no significant differences in sex distribution, CKD stage, comorbidities, or laboratory parameters, confirming successful randomization.

Quantitative Outcomes

As shown in Table 2, the completion rate for 24-hour urinary sodium excretion was critically low (24/99, 24.2%), precluding reliable estimation of between-group differences or definitive conclusions about behavioral change. Among the small subset of completers (n=24), median sodium excretion appeared lower in the intervention group (97.3, IQR 73.7 - 124.0) compared to controls (154.4 mmol/day, IQR 123.2 - 190.9). However, inferential testing was not conducted due to insufficient power and selection bias concerns.

However, a significant improvement was observed in the secondary outcome of sodium control knowledge: intervention group participants scored 8 (IQR 7-8) versus 6 (IQR 6-8) in controls (z=2.84, *P*=.005). No significant differences were found in blood pressure, QOL (36-Item Short Form Health Survey [SF-36] and kidney disease targeted areas), or other physiological markers.

XSL•FO
RenderX

Table . Analysis of outcomes at 3-month follow-up by study group (N=97)[a].

Outcomes	Control (minimal digital; n=52)		Intervention (enhanced digital; n=45)		*z*	*P* value
	n[b]	Median (IQR)	n[b]	Median (IQR)		
Sodium control knowledge score	50	6 (6-8)	40	8 (7-8)	2.84	.005
SF-36[c]	49	2515 (2355-2640)	40	2535 (2315-2780)	1.06	.30
KDTA[d]	49	3375 (3048-3755)	40	3535 (3082-3939)	0.78	.44
Systolic blood pressure (mm Hg)	52	126 (112-141)	45	125 (112-139)	−0.22	.83
Diastolic blood pressure (mm Hg)	52	78 (72-88)	45	80 (73-88)	0.45	.66
Heart rate (beats/min)	52	80 (78-85)	45	80 (78-86)	0.38	.70

[a]Completion rate for 24-hour urinary sodium excretion was 24.2% (24/99). Between-group comparisons were not performed due to low adherence and risk of selection bias.

[b]Number of participants with available data for each outcome.

[c]SF-36: 36-Item Short Form Health Survey.

[d]KDTA: kidney disease targeted areas.

Qualitative Findings

Overview of the Patient Journey Map

Thematic analysis was conducted among 23 intervention completers; noncompleters were not interviewed due to resource constraints. Sensitivity analyses indicated that the exclusion of noncompleters may reduce the representativeness of the patient journey map. Consequently, all findings are restricted to participants who completed the enhanced digital intervention. Data saturation was assessed retrospectively after coding all 23 interview transcripts and was reached at the 18th interview, with no new themes identified in the subsequent 5 interviews. The analysis revealed a dynamic patient journey, summarized in Table 3. A patient journey map typically consists of a horizontal axis (timeline) and a vertical axis (task axis). Guided by Empowerment Theory, this study divides the typical journey of patients with CKD in a digital sodium restriction intervention along the horizontal axis into three phases: (1) initial contact and expectation phase (week 1); (2) sustained interaction and empowerment phase (weeks 2 - 4); and (3) platform-facilitated relationship evolution phase (week 5 and beyond). The vertical axis encompasses 4 dimensions—tasks, emotions, pain points, and needs—yielding a total of 28 themes. These themes capture the realities, emotional shifts, barriers, and needs faced by patients at each stage of the digital sodium restriction intervention, comprehensively mapping the storyline across different dimensions throughout each phase. This reveals the dynamic evolution of patients from adherence to self-empowerment during the digital sodium restriction intervention, ultimately forming a typical patient journey map for patients with CKD in such interventions, as shown in Figure 3.

Figure 3. Patient empowerment journey among enhanced digital intervention completers.

Initial Contact and Expectation Phase (Learning-Adapting-Depending)

Participants described initial excitement and hope (“I wanted to try anything that could help my kidneys” [P5/13]), which was quickly tempered by information overload and technical anxiety (“So many messages… I didn’t know what to do first” [P7]). Key barriers included difficulty navigating the app interface and uncertainty about correct data entry. Emotional dependency on nurse feedback emerged as a critical motivator for early adherence.

Sustained Interaction and Empowerment Phase (From Passive to Active Management)

As familiarity grew, participants transitioned from passive compliance to active self-monitoring and habit formation. Many reported checking food labels spontaneously (“Now I always look at the nutrition facts” [P5/7/21]) and using salt substitutes. Personalized feedback and peer comparison features enhanced motivation. However, digital fatigue (“It felt repetitive after a while” [P18]) and social resistance (“My family said the food was too bland” [P1/9]) emerged as significant challenges.

Platform-Facilitated Relationship Evolution Phase (Identity Integration)

In later stages, participants began identifying as health managers rather than passive patients. They shared knowledge with family members (“My kids now remind me not to eat pickles” [P13/16/20]) and advocated for healthier meals. Despite these positive shifts, motivational decay and content monotony threatened long-term engagement. Participants expressed strong desires for expanded educational content (eg, protein and potassium management) and ongoing community support.

Mixed Methods Integration

Integrated analyses were performed using a joint display matrix (Table 4) following GRAMMS guidelines for mixed methods reporting. Three patterns of integration were identified. First, convergent findings demonstrated significant improvements in sodium-related knowledge in the enhanced digital intervention group (z=2.84, P=.005). These quantitative improvements were supported by qualitative accounts of clear, structured learning and enhanced confidence in sodium management, providing consistent support for the improvement in knowledge gains observed in the quantitative analysis. Second, supplementary findings highlighted a critical measurement paradox: completion of 24-hour urinary sodium collection was only 24.2% (24/99). Qualitative data further identified substantial procedural burden and poor compatibility with daily routines as key barriers, indicating that the gold-standard assessment itself impeded adherence. Third, explanatory findings clarified the absence of significant between-group differences in blood pressure or QOL (P>.05). Identified barriers, including family resistance, digital fatigue, and limited long-term support, explained why improvements in knowledge did not translate into measurable changes in clinical or patient-reported outcomes. No divergent findings were observed. The integrated synthesis indicates that although the intervention improved sodium-related knowledge, translation into behavioral and clinical changes was limited by implementation barriers and measurement burden.

XSL•FO
RenderX

Table . Joint display matrix for mixed methods integration.

Quantitative outcome	Qualitative finding	Integration type	Integrated interpretation
Sodium control knowledge: intervention 8 (7-8), control 6 (6-8); z=2.84, P=.005	Participants reported clear learning, easy-to-understand modules, and increased confidence in sodium management.	Convergence	The intervention effectively improved sodium-related knowledge, consistent with participant experience.
24 h urine completion: 24.2% (24/99); 75.7% (75/99) missing	Participants reported high burden, time intensity, and poor fit with daily life; urine collection was the top barrier.	Supplementation	Low completion is explained by substantial patient burden, revealing a "measurement paradox" in gold-standard outcome assessment.
BP[a] or QoL[b]: no significant between-group differences (P>.05)	Barriers included family resistance, digital fatigue, repetitive tasks, and insufficient long-term support.	Explanation	Neutral clinical outcomes are explained by real-world implementation barriers that prevented knowledge from translating to behavior change.

[a]BP: blood pressure.

[b]QOL: quality of life.

Discussion

Principal Findings

This study found that the nurse-led digital intervention improved participants' sodium-related knowledge as a secondary exploratory outcome. However, the completion rate of the primary outcome (24-h urinary sodium collection) was only 24.2% (24/99), which precluded evaluation of the intervention's true efficacy. These findings are consistent with Orem Self-Care Deficit Nursing Theory. Qualitative interviews identified a 3-phase patient engagement journey: initial enthusiasm, active participation, and subsequent disengagement driven by digital fatigue and family barriers. Overall, while digital interventions can enhance health knowledge, high-burden assessment tools and poor adaptation to daily life significantly hinder sustained behavioral changes.

From Information Delivery to Multidimensional Empowerment, Bridging the Knowledge-Action Gap

The improvement in knowledge without obvious behavioral changes supports Orem theory, which holds that self-care agency requires adequate knowledge, skills, motivation, and environmental support [36-39]. This reflects a typical knowledge-action gap. Digital tools can efficiently disseminate standardized health information on a large scale, but knowledge alone cannot drive long-term behavioral changes [40-43]. Sodium restriction is affected by family dynamics, cooking habits, and taste preferences—factors far more complex than simple information delivery [44,45]. Therefore, future interventions should shift from one-way knowledge popularization to multidimensional empowerment, comprehensively addressing both structural and interpersonal barriers [46-48].

Selecting Scientifically Sound and Feasible Outcome Measures

This study revealed a measurement paradox. Although 24-hour urine collection is the gold standard for sodium intake assessment [49], its complicated operation and heavy burden lead to low patient adherence and high measurement error [50,51]. This phenomenon aligns with Orem's view that self-care interventions must match patients' actual capabilities, which limits its application in clinical practice and research. By contrast, the spot urine sodium-to-creatinine ratio is simple to operate and has been validated to predict disease progression in multiple studies [52,53]. AI-based real-time urine testing may balance accuracy and convenience; however, its reliability across different patient groups requires further verification before large-scale application [54-56]. We therefore suggest researchers prioritize outcome measures that offer both scientific rigor and real-world feasibility, rather than pursuing methodological purity at the expense of practicality, to improve the clinical translation of research findings.

Constructing a Dynamic, Stage-Matched Intervention Framework

Family resistance, lifestyle constraints, and digital fatigue are key barriers to long-term intervention effects [57-59]. Digital health success relies on continuous patient engagement rather than short-term adoption [60-62]. Based on Orem's self-care theory, we propose a stage-matched intervention framework that includes 3 core components: deficit identification, compensatory support, and self-care capacity improvement [63]. In the initial stage, medical staff identify patients' knowledge gaps and practical obstacles to build trust. In the middle stage, personalized digital guidance is used to improve patients' self-efficacy and bridge capability gaps. The later stage helps patients maintain healthy behaviors through community interaction and independent self-care management. This framework transforms static, one-size-fits-all intervention modes into adaptive, dynamic support that addresses the multidimensional self-care deficits in CKD sodium management. Future mixed methods studies should further explore the mechanisms of patient engagement to inform the development of truly patient-centered digital intervention solutions.

Strengths and Limitations

This study adopted a parallel mixed methods design. Combining quantitative data and qualitative narratives clarifies intervention effects and their underlying mechanisms—an integrated approach that remains underused in digital therapeutics research.

XSL•FO
RenderX

Conducted in routine outpatient settings without additional resource input, the study demonstrates good ecological validity and practicality. The proposed patient empowerment pathway also provides a new perspective for exploring digital health engagement among patients with CKD.

Several limitations of this study should be acknowledged. First, the 24.2% (24/99) completion rate of 24-hour urine collection resulted in massive missing data, rendering ITT analysis and primary outcome testing invalid. Consequently, the true intervention effect could not be confirmed. Second, qualitative participants were limited to intervention completers, which may introduce selection bias, potentially overestimating engagement and underestimating implementation barriers, even after sensitivity analysis. Third, the single-center setting and small sample size limit the generalizability of findings across geographic, demographic, and statistical dimensions. Fourth, we did not analyze outcome differences across CKD stages 1 to 5, further limiting the applicability of the results.

Conclusions

This exploratory mixed methods study indicated that the nurse-led digital sodium restriction intervention was associated with modest gains in participants' sodium-related knowledge as a secondary outcome. However, this study encountered prominent practical difficulties in implementing high-load outcome monitoring, with the completion rate of 24-hour urine collection reaching only 24.2% (24/99). The misalignment between idealized trial protocols and patients' daily realities underscores the need for more feasible, patient-centered outcome measures and adaptive intervention designs. Rather than drawing conclusions about efficacy, this study provides critical insights into implementation barriers and informs the development of future person-centered digital tools. Digital health interventions may be improved via technical enhancements and better adaptation to patients' daily lives. Future research should use implementation science and mixed methods to explore intervention mechanisms, thereby narrowing the gap between health knowledge and self-management in chronic disease management.

Acknowledgments

We would like to express our sincere thanks to all the participants who participated in this project and helped us complete the entire study. We also thank Senmei Company (Chongqing) for providing us with technical support and the Department of Nephrology at the Second Affiliated Hospital of the Army Military Medical University for providing us with the research platform, which ensured that our research was successfully completed. Generative AI was used for post-text verification.

Funding

This study was supported by the Chongqing Technology Innovation and Application Development (Key Research and Development Project; grant number CSTB2023TIAD-KPX0060) and Chongqing Municipal Science-Technology Bureau and Health Commission jointly funded the project (grant number 2022MSXM026).

Abstract

Background: Substance use disorders are chronic conditions with significant personal and social consequences. Nursing care plays a key role in outpatient and community-based rehabilitation programs, yet patients' perspectives on this role remain underexplored.

Objective: This study aimed to explore how patients with substance use disorders perceive and interpret nursing care in community addiction treatment centers operated by the Spanish Red Cross in Madrid, Spain. Specifically, it sought to describe the organizational and care-related roles attributed to community addiction treatment centers and analyze patients' perceptions of nurses' technical and relational functions.

Methods: A phenomenological qualitative design was used. Fourteen in-depth, semistructured interviews were conducted with patients undergoing treatment at Red Cross centers. Participants were selected through purposive sampling to ensure diversity in age, gender, substance use, and treatment experiences. The data were analyzed using systematic text condensation and supported by the ATLAS.ti software.

Results: The center is perceived as a significant space not only for offering healthy leisure activities outside the context of substance use but also as a supportive environment that fosters a sense of belonging to a community. Patients valued the emotional support, empathy, and relational care provided by nurses, often highlighting their role in building trust and offering personalized attention. However, there was limited awareness of nurses' technical competencies.

Conclusions: These findings underscore the importance of holistic, patient-centered care and the need to enhance the visibility and recognition of nursing roles in addiction treatment settings.

KEYWORDS

nurse's role; nursing staff; qualitative research; substance-related disorder; psychiatric nursing

Introduction

Background

Substance use disorders (SUDs) are defined by the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*) as the "association of cognitive, behavioral, and physiological symptoms that indicate that the person continues to use a substance despite significant problems related to that substance" [1]. Globally, substance use represents a major public health concern and contributes substantially to the burden of disease, being associated with increased mortality, disability, and chronic conditions, such as liver disease, cancer, and infectious diseases [2-4]. SUDs commonly coexist with psychiatric disorders, particularly mood and anxiety disorders, which complicate treatment and worsen prognosis [3,5,6]. Consequently, SUDs can have a profound impact on a person's identity, causing individuals to lose their sense of self, which can manifest itself as a change in values and priorities, a deterioration of self-image, social disconnection, or a break with previous roles [5,6].

This individual impact underscores why SUDs represent a global challenge with serious consequences at the individual level. In 2025, there were 51,255 admissions to treatment for

XSL•FO
RenderX

psychoactive substance dependence in Spain, representing an increase of 9.7% over the previous year [7]. Moreover, adherence to rehabilitation programs is often limited, with high dropout rates reported internationally and frequently linked to psychosocial vulnerability and difficulties in establishing therapeutic relationships with health care professionals [3].

Beyond physical and mental health consequences, SUDs also affect identity and social functioning, contributing to stigma, social disconnection, and loss of social roles [3]. In Europe, treatment demand continues to rise, with 51,255 admissions for psychoactive substance dependence recorded in 2025, representing a 9.7% increase compared with the previous year [7,8].

Although SUDs affect people of all genders, treatment-seeking populations in community addiction services are often predominantly male, which may lead to the underrepresentation of women's experiences in qualitative studies [6-8]. This is of relevance given the established role of gender in shaping pathways into substance use, the associated stigma, exposure to violence or trauma, caregiving responsibilities, and help-seeking behaviors. These factors might shape how nursing care is perceived and what forms of support are most beneficial. Therefore, incorporating a gender perspective might be essential when interpreting patients' accounts and designing nursing interventions in community addiction treatment centers [9].

Prior Work

Evidence-based rehabilitation programs have been shown to reduce the use of illegal opioids and improve patients' physical and mental well-being, as well as their quality of life [8]. These programs adopt a holistic approach, with a multidisciplinary team comprising nurses, psychologists, physicians, social workers, and occupational therapists. Furthermore, the centers where these programs are implemented administer substitution treatment and provide social support and nursing care [8,10]. The ideal outcome of substance use rehabilitation is a state of balance and control, where the person feels empowered to manage their life without relying on substances that alter their mental state [7,8]. This process involves a reconstruction of the individual's identity through a series of behavioral modifications, facilitated by health care professionals [7,9,10]. However, it is estimated that up to 40% of patients withdraw from these programs. In this context, the support and participation of a multidisciplinary team, including nurses, is an empowering element in addressing this condition [11].

The concept of care is understood as a natural phenomenon. The patient's world, vulnerability, health, and suffering form the core of this concept [12]. The science of care not only facilitates the treatment of disease but also addresses patients' emotional and social needs, thereby promoting their overall well-being. The quality of care is known to improve when health care professionals make a conscious effort to understand the world from the patient's perspective. This, in turn, strengthens the therapeutic relationship and promotes better care outcomes. A profound understanding of the experiences and perspectives of patients with SUDs is imperative for the development of patient-centered care. This knowledge facilitates the design of personalized interventions, tailored to the specific needs of this vulnerable population [13,14]. By exploring the subjective experiences of these patients in relation to their care, areas for improvement in health services can be identified, more empathetic and culturally sensitive practices can be promoted, and barriers to access and adherence to treatment can be addressed. This comprehensive strategy for addressing SUDs has the capacity to markedly enhance patients' quality of life, diminish the social disapproval associated with substance use, and ensure optimal long-term therapeutic outcomes [15].

Despite the presence of nursing in SUD rehabilitation programs, the literature indicates that its role continues to be invisible and poorly understood by both patients and society. In community and outpatient settings, nursing work tends to be diluted within the multidisciplinary team, making it difficult to identify its specific functions [13,14]. However, in addiction treatment centers (CATCs), nurses carry out key interventions that include comprehensive patient assessment, clinical follow-up, health education, administration and supervision of substitution treatments, early detection of relapses, crisis care, and, especially, the establishment of a therapeutic relationship based on trust and continuous support during the rehabilitation process [16]. This apparent contradiction between the relevance of care and the low social recognition of the nursing role justifies the need to explore how users themselves perceive and understand this care [13,17].

Study Objectives

However, there is a significant gap in the literature on the perception of patients with SUDs regarding the role of nurses in rehabilitation programs [16,17].

The primary aim of this study is to explore the experiences and perceptions of patients with SUDs regarding the nursing care they receive in outpatient and community settings in Spain. Specifically, the study seeks to analyze patients' perception of the role of nursing staff, considering both the technical and relational dimensions of nursing care as experienced by users and to describe the organizational and care role that users attribute to Red Cross CATCs in Madrid (Spain), including resources, routines, and processes involved.

Methods

The question of how the role of nursing is perceived in the context of patients with SUDs undergoing rehabilitation programs lends itself to a qualitative approach, specifically a phenomenological study. Qualitative research focuses on understanding the world of the participants [18].

Study Design

The researchers were interested in how patients recover from SUDs and how they perceive the role of nurses in this process. It was therefore determined that qualitative research would best meet the objective. To gain a deeper understanding of this experience, a phenomenological study was conducted, as in-depth interviews allow the emotional, social, and personal nuances of the rehabilitation process to be captured, as well as the importance of support from nurses [19-21]. This research was conducted based on the recommendations of the COREQ guide [22].

XSL•FO
RenderX

Participants

Patients diagnosed with SUDs according to the *DSM-5* [1] were selected.

Eligibility Criteria

The inclusion criteria established at the beginning of the study were as follows: participants had to be enrolled in a rehabilitation program, be over 18 years of age, and be able to speak Spanish. Patients who did not wish to participate in the study or who were physically and/or mentally unable to complete the interview properly were excluded from the study.

Study Sample

A sample of participants was intentionally selected to represent a range of age groups, socioeconomic backgrounds, recovery times, genders, and experiences regarding substance use and the impact of nurses during the rehabilitation process. Furthermore, the data were collated pertaining to the participants' date of birth, gender, marital status, substance of abuse, alcohol consumption, and number of prior admissions to rehabilitation programs (Multimedia Appendix 1).

Of the 15 participants, 14 were male, and 1 was female. The ages of the participants ranged from 32 to 78 years (Table S1 in Multimedia Appendix 1). The participants' demographic profile was as follows: 8 were unmarried, 4 were divorced, 2 were married, and none were widowed. The participants consumed a variety of substances, including alcohol, cannabis, cocaine, heroin, opioids, methamphetamines, ecstasy, ketamine, hallucinogens and magic mushrooms, spice, mephedrone, salvia, gamma hydroxybutyrate, and lysergic acid diethylamide. The substances most frequently used were cannabis, heroin, cocaine, and alcohol. The number of previous admissions to rehabilitation programs ranged from 1 to 10. All participants were enrolled in the Red Cross rehabilitation program in Madrid, Spain.

Access to the Population

Initially, the researchers identified the various support structures for treatment and posttreatment within the Red Cross organization. In-depth interviews were conducted at 2 Red Cross CATCs in Madrid (Spain).

The management team and the multidisciplinary team at the centers were contacted, and meetings were organized to discuss the research objective and obtain the help of the various professionals in identifying participants. Participants were recruited through purposive sampling, following a preliminary presentation of the study to patients at the Red Cross centers together with the center's management team. Factors that would facilitate a more nuanced categorization of the work were considered, particularly regarding the perception of the nursing role in individual interviews.

Data Collection

In-depth, individual, semistructured interviews were conducted in person with 15 participants. One participant decided to leave the interview after 14 minutes of recording, so a total of 14 patients completed the interviews. The average interview duration was 45 (SD 15.3) minutes, and the interviews were conducted in convenient settings, such as individual rooms at the CATCs, to ensure privacy. The interviews were conducted between January and April 2023. All interviews commenced with the following opening statement: "Please provide a brief overview of your professional background and the circumstances that led to your involvement in this field." The flexibility of this qualitative interview methodology enabled participants to share their experiences from their own perspective. Open-ended questions and prompts were strategically used to explore turning points, support, situations, and coping strategies when participants were reluctant to share them. The following questions and prompts were included: "Please find below a list of the key responsibilities that nurses in this institution typically have" (Multimedia Appendix 1). With the prior consent of the participants, the interviews were audio recorded. The data collection protocol for the interviews was consistent for all patients. Interviews were transcribed immediately after completion. Data collection ceased once sample saturation was reached [23].

Trustworthiness

The criteria used to ensure reliability, in accordance with Guba's contributions to naturalistic research, encompass credibility, transferability, dependability, and confirmability [24].

Credibility

All interviews were recorded, and the exact duration of each session was documented, with additional field notes providing further elaboration and complement.

Transference

The processes followed, both for data collection and subsequent analysis, have been described in detail.

Dependence

The data collection process and the instrument used for conducting the interview have been delineated and included (Multimedia Appendix 1). Furthermore, members have been added to the working team at different stages to carry out triangulation processes in the negotiation of meanings.

Neutrality

The saturation of messages and the inclusion of direct quotes in the final report ensure neutrality in the analysis of the data.

Analysis

The transcriptions of these recordings were then produced. Subsequently, a comparison was made between the recordings and transcripts to ensure accuracy. Thereafter, a systematic condensation of the text was carried out in the analytical process, with the following 4 steps [25]: first, the transcripts were read to obtain an overview and identify preliminary themes, with annotations made in the text. Second, a series of codes and code groups were developed. In the event of the emergence of divergent codes, the most appropriate ones were agreed upon to develop a shared understanding. Third, each code group was identified and condensed into categories, which were incorporated into the report, with relevant quotes selected for inclusion. Finally, the condensed subgroups were synthesized to generalize descriptions and concepts of the patients' experiences [26,27]. The data analysis was iterative and began

XSL•FO
RenderX

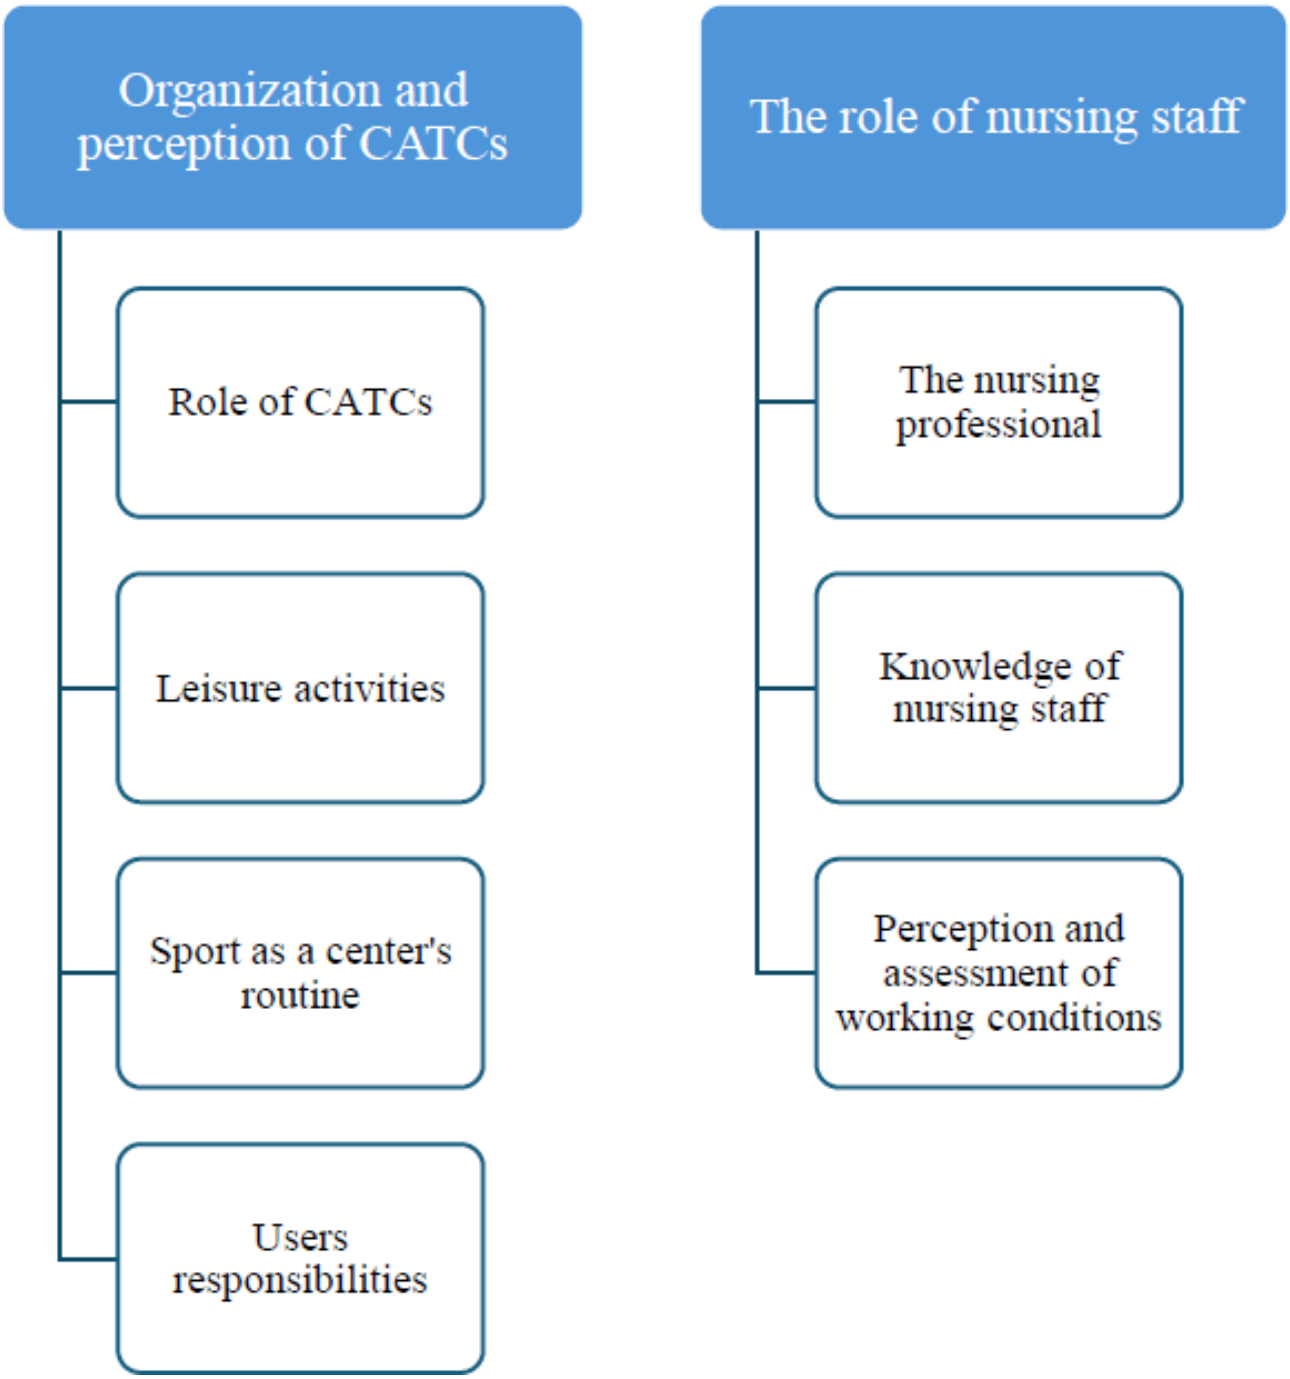
concurrently with data collection, using the constant comparison method as described by Strauss and Corbin [23] to identify commonalities and variations across cases progressively incorporated.

The ATLAS.ti program (version 25.0.1) was used for the analysis, as were the Office suite and Microsoft Excel for descriptive data analysis, and Microsoft Teams for facilitating digital collaboration during coding.

Ethical Considerations

This study has been approved by the Ethics Committee of the Complutense University of Madrid (Reference: CE_20221215 - 06_SAL). Furthermore, the study was conducted in accordance with the principles set out in the Declaration of Helsinki. In addition, to comply with the code of ethics for good practice in the collection of information for this research project, the resources provided by the Complutense University of Madrid have been accessed. The data have been anonymized, with all names appearing in the text being fictitious (Table S1 in Multimedia Appendix 1). Reasonable and appropriate physical, administrative, and technical measures have been taken to protect personal data from loss, misuse, unauthorized access, disclosure, alteration, or destruction. Participants were at liberty to accept or decline participation, and those who agreed to participate signed consent forms. It is important to note that no form of compensation was provided or offered to any of the participants.

Results



Participant Characteristics

All participants had received a confirmed diagnosis of SUDs prior to the interview. Of the 15 participants, 14 were male, 8 (54%) were single, 5 (33%) were divorced, and 2 (13%) were married. The mean age of the subjects was 48.2 years (SD 9.28). The substances most frequently consumed were cocaine—used by 13 (86%) of the participants—cannabis and alcohol (Multimedia Appendix 2). The mean number of previous admissions to rehabilitation centers within the sample was 2.5 (SD 2.4).

In the following section, the results of the empirical investigation will be presented. The data obtained from the interviews have been organized into 2 overarching categories, which are related to the research objectives and questions (Figure 1). All these categories have been framed from the perspective of the users.

XSL•FO
RenderX

Figure 1. Emerging categories from patient narratives: organization of community addiction treatment centers (CATCs) and the nursing role.

The Role of CATCs

Key Functions of CATCs

The role of Red Cross CATCs is pivotal in helping participants to stop using substances. The interviews revealed several issues. First, these centers play a significant role in helping individuals stop using substances, particularly through measures such as prescribing methadone as a substitute for heroin: “This is how I became acquainted with the CATCs and the process of heroin substitution” (Óscar). It was also noted that the center offers users the possibility to have meals on-site and to receive support with various arrangements, including transport and mobility-related matters. “Additionally, my transport card is being loaded, which is a modest amount of four euros and a few cents” (Óscar).

The same user commented on the existence of these rehabilitation centers. He said that he had gone “to a hospital because I didn’t know that the CATCs existed” (Óscar).

Leisure Activities

The importance of leisure activities in the daily lives of participants emerged as a recurring theme in the interviews, with all interviewees highlighting it as a central focus. Javier succinctly summarizes the routine of a typical day at the center, characterizing it as “attending therapy sessions.” This assertion is corroborated by the observations of other participants, such as Oscar, who states: “At the Red Cross therapy centre (...) it

XSL•FO
RenderX

helps me a lot because I was busy all day and I didn't have any nonsense going through my head." These centers, as a result, organize a variety of activities and "workshops on drugs, gender, reading ..." (Chema), which are emphasized in the interviews. Daniel elucidates the manner these centers provide support:

> *It's like, like, like a house where you can't just sleep. They also make us feel like this is our home. The Red Cross treats us very well and they really love us; they truly love us. I mean, it's not just a pat on the back and that's it. They are ... it's a complete embrace, from heart to heart.*

As well as the points raised by Chema, there have been repeated mentions of board games, music, and dance workshops. The latter has been of particular interest, given the work carried out by the volunteer running them:

> *She herself, who is not like all the other workshops that are all about that, about drugs, about you, about these, about others ... No, she plays music and says, "Now you do whatever you want" and "Now you dance, and now you ... and now everyone together here and now everyone there ... now everyone ..." I mean ... she makes you forget everything at that moment. No, you don't think about your problems, you don't have time to think about anything bad, or anything that could hurt you, that could ... She doesn't give you time, she doesn't let you. She's full of life.* [María]

Sport in the Center's Routines

Sport has also been mentioned in numerous interviews, often referred to as "sports activities in the morning" (Paco). To that end, the following activities have been outlined:

- "Playing table tennis or cycling or exercising." (Rodolfo)
- "Some days it's Tai Chi, other days they go walking." (Maria)
- "I played volleyball, which I hadn't played in years." (Roberto)
- "Now we are cycling." (Antonio)

In addition, sport has been referenced on a single occasion as a concomitant treatment for other conditions: "I come walking to get some exercise because of my diabetes" (Chema).

Users' Responsibilities in the Centers

Leisure time is also spent carrying out different responsibilities assigned by the center:

> *Oh, and if it's your turn to do the office work, you have to set the table. If it's your turn to wash up, you have to wash up too, and so on.* [Fulgencio]

> *"As for routines ... we have a plan too ... there's a ... a notebook where they write down when we have to prepare meals, wash the dishes ... That's how we keep busy. .. the manager of the centre writes it down for everyone. And on days when it's my turn, it's someone else's turn ... When it's my turn, I have to serve the tables, then clear the dishes, take out the rubbish bins ... and so on, routine stuff ... To clean the dishes, then dry them ... That's how it works, I don't know, to keep us busier.*" [Óscar]

> *Then one day it's your turn to wash the dishes and another week you're in charge. You're responsible for distributing the food and so on, but hey, they're supervising you.* [Rodolfo]

Functions of the Nursing Professional

Role of Nurses in CATCs

A variety of professionals are employed in these centers, including nurses, doctors, psychiatrists, psychologists, and occupational therapists. Nurses have been the central focus of the work, and they have taken up a large part of the interview time. The functions of nursing staff are those that have been most frequently mentioned in the coding process, in relation to the perception of this group. It is generally understood that the profession is held in high regard by its users. There are some very compelling testimonials in this regard:

> *At the Jiménez-Díaz Foundation, nurses treat you excellently. I can't say anything bad about healthcare here in Spain or about the nurses, they are all lovely and very professional.* [Roberto]

These comments are not isolated, as they are reinforced by other comments that echo the same sentiment.

For example, Roberto stated:

> *The nurse who works with the doctor [at the CATC] (...) is a lovely girl, she is super friendly, she is a sweetheart. Professionally, she is excellent, as they say. And also, she was very concerned and asked me: are you okay?*

Daniel also commented that "the treatment by the nursing staff [at the CATC] was very good, very good, very good." He particularly highlighted the treatment by the nurse above all others. When asked about the care that had meant the most to him, he pointed to the emotional support provided by a nurse:

> *I'm very clear about this. It's (...) a nurse I had at the shelter [at the CATC] (...), accompanying me to an ambulance because I have tinnitus. Then they were saying bad things to me, and she was the first person I talked about it. And that, and how she accompanied me and went down the stairs with me ... I was shaking because I didn't want to go to the ambulance, I didn't want to go there. I was terrified of being alone for even a second with the voice. And that's the most the nurses have done for me.* [Daniel]

On occasion, this positive perception was intertwined with the work of the entire team, as Antonio noted:

> *Here [at the CATC] we have a psychologist, a social worker, a nurse, the manager, very good people, the workers too. They get angry, which is normal sometimes, but they are people.*

The testimonies are intricately interwoven throughout the interview, thereby underscoring the human dimensions of the nursing professional. Various statements highlight the staff's

XSL•FO
RenderX

attentiveness and their provision of empathetic listening and support, in response to the most useful care they have received:

> *Therapies where you can talk, like two people. You know what I mean? Being able to sit down, two people. You, with a therapist, being able to sit down and have .. him being able to tell you about his problems and you being able to tell him your problems, having someone there to talk to unburden yourself. Telling him, "Look, I got out of bed and cried." I cried because of this, because of this and because of this, and being able to tell you ... your things and him being able to tell you his things.* [Jorge]

> *This girl … the girl on the other side, at the Red Cross [at the CATC]. She ... I saw that she was concerned about my situation the first day I went there. I ... I thought she was a psychologist rather than a nurse, from the time I spent talking to her and expressing my feelings, my experiences, where I came from, where I was going, and why I found myself where I was. I was there for, I don't know, two hours, three hours, talking to her, and she was a nurse, not a psychologist. And she was concerned about ... about how I was doing.* [Jero]

Even when pointing out other functions, Paco considered that

> *the way the staff [at the CATC] treat you is what matters most ... because that's what affects you the most. But then, of course, each person ... the pills and so on ... also have an influence. But ... the way they treat you is what attracts you the most.*

Rehabilitation programs were also identified as particularly valuable forms of care, with participants citing the significance of being listened to in difficult situations:

> *My nurse [at the primary care centre], who has helped me to trust her a little, weigh myself, tell her when I have used drugs and when I haven't, give thanks, I am grateful to the people who have been helping me since 2015. And even though I messed up and stuff, they did everything they could to help me (...) see what we needed.* [Óscar]

In other words, the same patient insisted:

> *She was teaching nursing classes here, for everyone. That was very positive because there were classes on all kinds of illnesses, how to use pills ... There were also classes on quitting smoking, how to quit smoking ... There are workshops for people who want to quit smoking too. These workshops are run by nurses. That's all I can say for now because I can't remember anything else.* [Óscar]

María was very clear on this point: "They [at the primary care center] ... do a bit of psychology and nursing, kind of combining the two." Another user, Jero, who had already pointed out the importance of nursing staff's ability to listen, emphasized the importance this can have in other therapeutic aspects, such as methadone use:

> *Well, if this is the first day—I said—"it shouldn't take too long." He [at the CATC] offered me something ..., which was methadone, and I said, "Look, I don't want that, I've never taken that in my life, but I'm afraid, because I've heard that there are people who spend their whole lives taking that crap." I said, "Well, let's start with a very, very small amount. Let's see if that's enough for you and then we'll reduce it." "Okay, I'll accept it, because of the way you've treated me, because I can see that you're someone who cares about the situation I'm in without knowing me at all, and because I've ... I've opened up to you and told you about ... my plans." It was really good, to be honest, that's the part I'm most grateful for.* [Jero]

Knowledge of Nursing Staff

During the interviews, references to the work of nurses were particularly prevalent, especially in discussions of more general topics and when the work functions of the entire team were intertwined. There are numerous examples of this phenomenon, particularly in relation to the role of the doctor. For instance, when asked about the duties of a nurse, Paco replied:

> *Well, we ... I, for example, go up to cognitive workshop, which was today ... to the girl in cognitive workshop [at the CATC]. And then, in case you have ... there's the doctor, the doctor in case something happens to you. I have a toothache and I ask him for ... a pill for toothache because it hurts and I still haven't ... I go to the medical centre by bus and I always forget to stop at medicine.*

Another patient intermingled the roles of different professionals in his reflections:

> *I haven't had much … much … much experience with nurses, because as I'm new, I haven't had much time. What I do have is a good day centre, which I've had for two days now, OK? And I only have experience with Susana, who is my psychologist, and with Dr. Felipe, I don't know if you know him. They are the only ones I have experience with.* [Roberto]

Comparisons were even drawn between nurses and doctors:

> *You know more. You are not doctors, but we can trust you more than doctors. I am quite bold, having been a salesperson all my life, so I don't mind, but ... I think a doctor can be more reserved than a nurse.* [Eduardo]

These relationships and role confusions are not exclusive to CATCs, as they also mentioned past experiences in which they highlighted the importance of nurses in primary care centers:

> *At the mutual insurance company, for example, this leg that I told you I hurt while cleaning ambulances, they treated me like a queen. Both in physiotherapy and in ... when it came to medication, creams, everything, and all for free.* [María]

> *Not everyone knows about nursing. There are things that if you have, if you have a wound here, you put*

XSL•FO
RenderX

> *Betadine on it or whatever and that's it. But there are things that they have to give you. They have to tell you, "Look, the stretch consists of squats, this, that and the other, OK?" (...) Well then, I think that time should also be used to ... I see that they devote a lot of time to older people [at the primary care centre].* [Maria]

Perception and Assessment of Working Conditions

Another noteworthy aspect that emerged from the interviews was related to working conditions, including issues of overburden:

> *Well, I can see that he's a bit overworked, but even so, he's always available [at the CATC]. Yes, if I could add something ... a little help, give him some assistance. Because he does tests, dispenses medication, sees patients ... You don't have to make an appointment with him. Because you talk to him beforehand and Julián is immediately available.* [Chema]

> *Appointments take a long time. For example, those at the public centre and at the outpatient clinics too. Sometimes they can't see you, even if it's an emergency, because they have someone else who maybe ... well, you say it yourself ... I mean, I don't pay for my medication, do I? Because I earn very little. So there are times when I've had to buy the medication because I needed it at that moment because they don't have enough nurses [referring to nurses in outpatient/primary care consultations]. They keep cutting back instead of ... providing more for the population.* [María]

This same patient, María, concluded very clearly: "I think people should be given more permanent jobs."

Discussion

Principal Results

Patients with SUDs perceive nursing care positively, although they predominantly highlight relational aspects, such as accompaniment, active listening, and trust. In some cases, there appears to be a lack of awareness regarding nursing functions, particularly those within the scientific and technical domains. The results of this study provide valuable insight into how patients with SUDs value and interpret the nursing care they receive in outpatient and community-based rehabilitation programs in Spain.

From a phenomenological perspective, understanding patients' perceptions of the role of nursing requires first delving into their personal history of substance use. This is not merely a chronological account of events; it is a complex network of lived experiences, emotions, social relationships, and meanings attributed to the substance and its effects [28]. The mean number of previous admissions to rehabilitation centers in the sample was 2.5 (SD 2.4). This aspect also frequently features in patients' accounts, highlighting the chronic nature of SUDs and the difficulties in achieving sustained rehabilitation over time [4,7,28].

Participants offered a largely favorable evaluation of the center, regarding it as a vital asset in their rehabilitation process. This positive perception appears to be associated with the multidisciplinary team, comprising doctors, psychologists, social workers, occupational therapists, and nurses. The team's role is to address both the physical and psychological aspects of treatment and provide comprehensive support that extends beyond a purely clinical approach [12,13,15]. In their testimonies, participants highlight the professional and emotional support they received, as well as the feeling of belonging to a safe and structured environment that not only distances them from problematic consumption environments but also provides for their basic needs and offers opportunities for improvement in various areas.

On the other hand, participating in a variety of group activities, such as physical exercise, healthy leisure initiatives, and workshops focusing on integrating patients into the workplace and fostering personal relationships, was considered vital for sustaining abstinence. Physical exercise is widely used as a complementary therapy in SUD treatment. It is considered a healthy practice, as well as a meaningful and socially integrative activity [29,30]. Similarly, the other leisure workshops offered at the center are seen as potentially transformative by providing entertainment in environments unrelated to substance use and fostering a sense of belonging to a social group [28,29]. One possible explanation for these findings is that the center is perceived not only as a protective factor against relapses, but also as a safe resource for well-being and ongoing support. This finding is consistent with other studies addressing this issue but contrasts with previous studies documenting experiences of stigmatization and discriminatory treatment in hospital settings. The role of the multidisciplinary team could be pivotal in generating a positive overall experience that encourages adherence to the rehabilitation program and social integration [30,31]. This approach is consistent with the Schlossberg transition process model, in which the authors recommend that, to effectively cope with a transition—namely, rehabilitation from SUDs—people need access to diverse types of support [32]. These support categories can range from interpersonal relationships (such as sponsors and spouses) to more distant support systems (such as institutions and communities), including rehabilitation centers [33]. Consequently, rehabilitation programs that adopt a holistic perspective—combining respect for patient autonomy with a flexible and adaptable support structure—align not only with international standards but also with a patient-centered approach [7,10].

Regarding nursing care, the participants in our study recognize nurses as key figures in the rehabilitation programs of the Red Cross CATCs. Most of the nursing practices identified as beneficial by the participants in this study pertain to relational care interventions. They emphasize their close working relationships, active listening skills, and emotional support as key differentiating factors compared to other health care professionals in the multidisciplinary team. Furthermore, they place a high value on the involvement of nursing staff, particularly in health education, support in times of crisis, and management of withdrawal symptoms. This finding aligns with

XSL•FO
RenderX

the results of other studies, which indicate that patients with SUDs perceive increased support and reduced judgment from nursing professionals [34,35]. As demonstrated in previous research, the provision of compassionate care is of paramount importance, even in relation to other populations [36,37].

Comparison With Prior Work

This evidence indicates that the therapeutic relationship is fundamental for patients, regardless of their age or care setting. Skills, such as listening, communicating, and providing reassurance, are valued and recognized as essential, not as inferior or merely technical skills [38]. In addition, other studies have shown that relational interventions generate a wide variety of positive health outcomes. Research has demonstrated that effective therapeutic relationships can enhance treatment adherence and rehabilitation and reduce perceptions of stigma, as outlined in Parkhideh et al [39]. As demonstrated in the literature and as evidenced by our own findings, there is clear evidence of the importance that patients attach to being treated with respect and as people rather than as problems or diseases [40].

Among the recommendations expressed by users, the one that stands out is the suggestion that health care personnel show greater patience during care. This demand reflects a need for more humane and empathetic treatment and highlights the importance of the therapeutic relationship component. Patience is seen as a sign of understanding, respect, dignity, and a willingness to listen, which are all basic elements in building an effective working relationship. This is particularly relevant in contexts involving vulnerable populations, such as individuals with SUDs. Integrating this perspective into clinical practice has the potential to enhance the quality of care and ensure adherence to treatment [35,38].

However, there is a lack of knowledge regarding the roles performed by each member of the health care team. Although the role of the nurse remains constant within the team, participants confuse their role with those of doctors and social workers during the discussions. This is also evident from the absence of any codes or categories relating to other areas of nursing care. One potential explanation for these findings is that patients may not have had sufficient time to comprehend the nature of nursing work. However, it should be noted that all participants had previously been admitted to at least 1 other rehabilitation program. Therefore, the lack of knowledge about nursing work may not be attributable to a lack of contact with nursing staff, but rather to the invisibility of care. The extant literature supports this assertion. In both this population and the general population, care is often not directly associated with nursing. This may mean that the specific and specialized role of nurses in various contexts is not fully recognized. This lack of knowledge about nursing care reflects an underlying problem, which contributes to its social and professional devaluation [41,42].

The participants' accounts also allow us to infer a structural reality that affects the professional practice of nursing: the low institutional and social value placed on this group. This situation is evident in working conditions that often fail to reflect the complexity of the care required by patients with SUDs. These conditions include a lack of financial recognition, excessive workloads, a shortage of adequate rest areas for staff, and limited participation by nurses in decision-making spaces. This invisibility stands in stark contrast to the pivotal role that patients themselves ascribe to nurses in their recovery processes, particularly regarding human support, active listening, and the establishment of long-term therapeutic bonds [43]. This structural invisibility might help explain why some participants were uncertain about the specific responsibilities of each professional, occasionally mixing up nursing functions with those of other team members. This confusion may also arise from overlapping interdisciplinary tasks, inconsistent role introductions—particularly at admission or during care-plan changes—and contextual factors in SUD care, such as time pressure, staff turnover, and psychosocial vulnerability. Therefore, strengthening role communication and increasing the visibility of nursing responsibilities might enhance patients' understanding and recognition of nursing care within community addiction services [41]. Role ambiguity may also limit patients' ability to actively seek nursing support. Brief standardized introductions at admission, visible role identification, and, when feasible, assigning a reference nurse may improve clarity. Future research should further explore patients' perspectives on strategies to enhance understanding of nursing roles in care [41,44].

Limitations

This study is one of a limited number of research projects conducted in Spain that address the perceptions of a particularly challenging-to-reach demographic, such as patients with SUDs. However, it is vital to understand the experiences of individuals with SUDs and their interactions with nursing care in order to improve and personalize interventions and establish effective improvement strategies within this particularly vulnerable population. Nevertheless, this study presents some limitations. Most of the participants in the sample are male, and most of them self-identify as such. This finding is consistent with the available evidence, which points to a higher prevalence of substance use among men [2]. From a gender perspective, this pattern may be influenced by social constructs associated with masculinity. These constructs include the normalization of risk, pressure to demonstrate strength or autonomy, and perceived lower access to emotional support networks [4]. These factors may facilitate the initiation and maintenance of use and therefore bias the findings. Conversely, the participants were members of merely two centers belonging to the same rehabilitation Red Cross program, which may have exerted an influence on the results due to the absence of variety in the care received. Furthermore, no distinction was made between different types of nursing care (specialized, hospital-based, or based on the years of experience of the professionals). To expand the knowledge base regarding this population's perceptions of the nursing role, future studies involving samples of patients from diverse rehabilitation programs and incorporating a gender perspective are essential. Women's perspectives may be insufficiently captured in this study, and future research should purposively recruit more women (and gender-diverse participants when possible) to better inform gender-responsive nursing care in community addiction services.

XSL•FO
RenderX

Conclusions

This study demonstrated that SUD is a chronic condition, with multiple admissions to rehabilitation programs. Participants have provided a positive evaluation of the rehabilitation center, emphasizing the comprehensive support provided by the multidisciplinary team and the safe environment it offers, beyond clinical treatment. Group activities and ongoing support are key factors in maintaining abstinence and promoting social integration.

Patients with SUDs place a high value on the role of nursing, particularly relational interventions over technical interventions. However, this assessment contrasts with a lack of knowledge about certain functions of the nursing profession, which limits their ability to recognize and take advantage of their capacity for action in community settings.

These findings emphasize the necessity to enhance care models through a holistic approach, considering patients' life contexts and recognizing both individual care and structural conditions. Nurses can play an essential role in designing patient-centered interventions to achieve sustainable recovery and a positive therapeutic experience.

Acknowledgments

We would like to express our gratitude to the staff of Red Cross centers in Madrid for their crucial assistance in reaching out to patients.

Abstract

Background: Poor self-care impairs osteoporosis management. Disease-related knowledge and family support have influenced self-care; however, the combined association of these factors with self-care remains insufficiently understood.

Objective: This study aimed to compare self-care among individuals with osteoporosis who received a multicomponent supportive-educative mobile health intervention with that of individuals who received usual care.

Methods: This exploratory pilot study using a pretest-posttest design with a nonequivalent control group included 46 individuals aged 50 years and older who had been diagnosed with osteoporosis and were receiving care at the orthopedic outpatient department of a university hospital in Bangkok. Participants were matched by sex, age, and back pain scores and then sequentially allocated to an intervention group (n=23, 50%) and a comparison group (n=23, 50%). The intervention group received a 4-week multicomponent supportive-educative intervention based on Orem's self-care theory, delivered partly through a closed Facebook group. The intervention included educational guidance, video-based teaching, psychological support, family involvement, and remote nurse interaction. The comparison group received usual care. Self-care was measured using the Self-Care of Osteoporosis Scale. Chi-square tests, Fisher exact tests, independent-sample 2-tailed *t* tests, analysis of covariance, and multivariate analysis of covariance were used to examine differences between groups.

Results: After controlling for baseline self-care scores, participants in the intervention group had significantly higher postintervention self-care scores than those in the comparison group ($F_{1,43}$=459.29; P<.001). Significant group differences were also observed across all 3 domains of self-care after controlling for baseline scores. Compared with the control group, the intervention group demonstrated significantly higher postintervention scores in diet and physical activity ($F_{1,41}$=245.04; P<.001), safety performance ($F_{1,41}$=171.20; P<.001), and medication adherence ($F_{1,41}$=144.54; P<.001).

Conclusions: The multicomponent supportive-educative intervention delivered partly through Facebook was associated with improvements in self-care among individuals with osteoporosis. Future rigorous trials are needed to confirm its efficacy.

KEYWORDS

osteoporosis; self-care; telemedicine; family support; exercise; accident prevention

Introduction

Osteoporosis affects 23.1% of older women and 11.7% of older men worldwide [1]. It is associated with increased risk of osteoporotic fractures, particularly at the femoral neck (31.9%), spine (28.8%), and hip (9.9%) [2]. The causes of osteoporosis include reduced estrogen levels after menopause, inadequate intake of vitamin D and calcium, the use of certain medications (eg, anticoagulants), and certain diseases (metabolic and hormonal disorders) [3]. Effective management of osteoporosis relies on both medical treatment and individuals' engagement in self-care, including medication adherence, regular exercise, adequate dietary intake, and fall prevention, to reduce the risk of complications.

Self-care among individuals with osteoporosis remains a significant challenge. One study reported that 100% of women with osteoporosis did not engage in exercise, whereas mean daily calcium and vitamin D intake was 546.7 (SD 60.28) mg

XSL•FO
RenderX

and 2.0 (SD 0.34) µg, respectively [4]. Both values were below the recommended daily intake of 1000 to 1200 mg for calcium and 15 to 20 µg for vitamin D [5]. These behaviors include discontinuing medication without medical consultation [6]. Self-care for osteoporosis refers to behaviors undertaken to manage the condition and prevent complications. Nurses play a vital role in supporting and encouraging individuals with osteoporosis to adopt these self-care practices [7].

Past research has identified several factors influencing self-care in individuals with osteoporosis, including disease-related knowledge, social support, patient–health care provider relationship, medication-related side effects, and patient participation in treatment. In one study, poor disease-related knowledge was reported in 52.8% of patients and was associated with inadequate intake of vitamin D and calcium [8]. Social support and a strong patient-physician relationship have been positively associated with self-care behaviors [9]. Medication-related side effects, including those associated with self-administered Forteo, also influence medication self-care [6]. In addition, patient participation in treatment decisions has been linked to improved treatment outcomes [10].

Interventions to promote self-care among individuals with osteoporosis have been widely studied. These include educational video-based programs, group training sessions, telephone follow-ups, and support from health care teams. There is evidence suggesting that such interventions significantly improve medication adherence and reduce the risk of fractures [11,12]. However, most of the previous interventions focus primarily on individuals (participants engaged in the interventions themselves without the involvement of family members) even though many are older adults who may require assistance from family members and may find it difficult to follow instructions independently. Integrating family support with the supportive-educative nursing system by Orem et al [13], which emphasizes teaching, guidance, emotional support, and the creation of an environment conducive to self-care, may better address these needs and enhance self-care among individuals with osteoporosis.

In Thailand, 1 in 5 women aged 40 to 80 years has osteoporosis, and the prevalence exceeds 50% among those aged 70 years and above [14]. However, challenges similar to those in other countries persist; only 67.2% of individuals have adequate calcium intake, and overall levels of physical activity remain low [15]. These problems highlight the need for interventions to promote self-care among individuals with osteoporosis. With the rapid advancement of mobile health (mHealth) technologies and the widespread use of social media, these platforms offer promising opportunities for delivering supportive-educative interventions and promoting healthy behaviors, as reported in previous studies [16]. Family support also plays a significant role in enhancing self-care, as shown in previous studies [17]. Addressing this gap is crucial for enhancing self-care among individuals with osteoporosis. Therefore, this study aimed to compare self-care between individuals with osteoporosis who received a supportive-educative mHealth intervention and those who received usual care. We hypothesized that participants receiving the multicomponent supportive-educative mHealth intervention would demonstrate significantly higher overall self-care mean scores and higher individual mean scores in the 3 domains of self-care (medication adherence, diet and physical activity, and safety performance) than those receiving usual care.

Methods

Study Design

This exploratory pilot study used a pretest-posttest design with a nonequivalent control group. The study followed the TREND (Transparent Reporting of Evaluations With Nonrandomized Designs) checklist [18].

Study Setting

This study was conducted at an outpatient clinic in a 1200-bed university hospital in Bangkok. In 2025, a total of 256 individuals with osteoporosis received care at this hospital, where osteoporosis services are provided at the orthopedic outpatient department every Wednesday. Medical appointments are scheduled every 4 to 6 weeks.

Participants

Eligibility Criteria

Participants were individuals diagnosed with osteoporosis. Eligibility criteria were (1) age of 50 years or older, (2) receipt of treatment for 6 months or more, (3) residence with family members or relatives, and (4) either use of Facebook or having a family member who used Facebook. Individuals were excluded if they were severely ill; were scheduled for surgery during the intervention period; had speech or hearing impairments; or had cognitive impairment, defined as a score of 22 or lower on the Thai version of the Mini-Mental State Examination.

The sample size was calculated using an effect size of 0.8, a significance level of .05, a power of 0.80, and a *t* test, resulting in a required sample size of 21 individuals per group. Allowing for a 10% dropout rate, the final sample size was 23 participants per group.

Method of Recruitment

Eligible participants were consecutively identified by nurses at the time of clinic check-in. Nurses provided a flyer to invite them to participate in the study. Interested individuals were referred to the researcher, who explained the study procedures. During the enrollment period between July 2025 and August 2025, a total of 120 individuals with osteoporosis attended the clinic, of whom 88 (73.3%) were eligible and invited, and 46 (52.3%) agreed to participate. All individuals who declined participation were female. Participants were matched 1:1 based on sex, age, and back pain score because these variables influenced self-care [6,9].

Assignment Method

Participants were assigned alternately to the intervention and comparison groups in a 1:1 ratio. This assignment method was used to maintain comparable group sizes and facilitate group matching based on key participant characteristics.

XSL•FO
RenderX

Blinding

Due to the nature of the multicomponent supportive-educative mHealth intervention, blinding of participants and researchers was not feasible. Participants were aware of their group assignment, and the researchers delivering the intervention were not blinded.

Usual Care

During the study period, the comparison group continued to receive usual care. Nurses provided health education focusing on medication, diet, and exercise. This education was delivered orally, without the use of written materials or video clips for exercise demonstration. Individuals could confirm or reschedule their appointments through the hospital application.

Intervention Program

Intervention Description

The multicomponent intervention was delivered through a private Facebook group over a 4-week period (28 days). It consisted of 4 weekly 15-minute educational sessions conducted in small groups of 3 to 4 participants. Live Facebook sessions were held daily between 3 PM and 4 PM to accommodate participants' schedules. Each participant and 1 family member attended 1 session per week using a shared study-specific Facebook account. Participants who missed their scheduled session received a reminder from the researcher and attended a subsequent session. Outcome assessments of self-care were conducted at 2 time points: baseline and 1 week after completion of the intervention during face-to-face visits at the outpatient department.

The multicomponent intervention focused on three domains of self-care: (1) medication adherence, (2) diet and physical activity, and (3) safety performance. It was developed based on Orem's self-care theory [13], specifically the supportive-educative nursing system, and incorporated the helping methods by Orem et al [13] by (1) guiding and directing participants to strengthen self-care ability and decision-making; (2) teaching through four 10-minute educational video clips covering osteoporosis and medication, nutrition, exercise, and fall prevention; (3) providing psychological support through online family reflection sessions; and (4) creating a supportive learning environment through regular nurse-participant interactions (Multimedia Appendix 1). A printed handbook containing the same educational content as the 4 video clips was provided to reinforce learning throughout the intervention. An overview of the intervention is shown in Table 1.

XSL•FO
RenderX

Table . Intervention overview.

	Objectives	Key activities	Delivery method	Helping methods by Orem et al [13]	Monitoring and evaluation
Session 1 (baseline)	Establish relationships with individuals and families	• Introduce the intervention • Help participants and families share self-care experiences • Assess baseline self-care and back pain scores using an interviewer-administered questionnaire • Provide self-care handbook	Face-to-face	Guiding and directing	Baseline self-care
Session 2 (week 1)	Explain disease management	• Learn about osteoporosis, medication, nutrition, and exercise • Upload four 10-min video clips, which are available for repeated viewing • Participate in questions and answers	Online group session via closed Facebook group	Teaching	Ability to identify content from the video and handbook
Session 3 (week 2)	Reflect on self-care experience	• Facilitate the sharing of experience reflection sessions by participants and families applying self-care • Facilitate group discussion and questions and answers	Online group session via closed Facebook group	Supporting	Self-report on activities
Session 4 (week 3)	Apply strategies to improve home safety	• Shared experiences • Review environmental safety and accident prevention through video • Facilitate group discussion	Online group session via closed Facebook group	Supporting	Self-report of home changes
Session 5 (week 4)	Use available resources to sustain self-care	• Discuss barriers and apply problem-solving strategies • Engage family support • Reflect on resource use	Online group session via closed Facebook group	Providing an environment that promotes personal development	Family attendance

Family Involvement

Family members participated in all intervention sessions delivered through the Facebook group. They received the same educational content as participants and were encouraged to support self-care behaviors, including medication adherence, dietary management, physical activity, and home safety practices. During the sessions, family members were invited to share their experiences and discuss strategies they used to support participants in managing osteoporosis.

XSL•FO
RenderX

Facebook Group Privacy Protection

To protect their privacy, participants were asked to create new Facebook accounts exclusively for this study. Participants were instructed to use pseudonyms rather than their real names. Each participant and 1 family member shared the same study-specific account, resulting in 23 Facebook accounts. All live Facebook group sessions were conducted with participants' cameras turned off, and only pseudonyms were displayed during the sessions to maintain confidentiality.

Intervention Fidelity

Intervention fidelity was monitored throughout the study to assess intervention delivery and participant engagement. All intervention sessions were delivered by the principal investigator according to a standardized intervention protocol. Four educational videos covering osteoporosis and medication, nutrition, exercise, and fall prevention were uploaded to the private Facebook group. Facebook analytics recorded 71 views for the osteoporosis and medication video, 165 views for the exercise video, 73 views for the nutrition video, and 90 views for the accident prevention video. Because Facebook did not permit tracking of individual viewing histories or downloads, participant engagement was also assessed through attendance to the weekly live Facebook sessions. All participants attended 1 live session per week, resulting in a 100% (23/23) attendance rate across the 4 scheduled sessions for each participant.

Participants and their family members were asked open-ended questions about the educational content, video viewing experience, attendance to the online sessions, and implementation of self-care activities. Participants were able to accurately describe the educational content and discuss its application to self-care, indicating that all participants had viewed the videos. Any misunderstandings were clarified immediately by the principal investigator during the discussions. All 23 Facebook study accounts completed the intervention, and 3 (13%) participants who missed their originally scheduled sessions attended an alternative session after receiving a reminder from the researcher.

Outcome

The primary outcome was self-care, which was measured using the Self-Care of Osteoporosis Scale (SCOS) [7], a self-reported instrument.

Instruments

Overview

The SCOS, developed by Cittadini et al [7], consists of 15 items across 3 domains: medication adherence, diet and exercise, and safety to prevent accidents. The scale uses a 5-point Likert scale ranging from "never" (1 point) to "always" (5 points). The total SCOS score was calculated as the mean of the 15 item scores, yielding a possible score ranging from 1 to 5, with higher mean scores indicating better self-care behaviors. The original instrument demonstrated excellent internal consistency, with Cronbach α values of 0.94 for the overall scale, 0.84 for medication adherence, 0.88 for diet and physical activity, and 0.85 for safety performance. As the SCOS had not previously been used in Thailand, permission was obtained from the original instrument developer, and the instrument was translated using a standard forward-backward translation process followed by expert review. In the present study, the Thai version demonstrated acceptable internal consistency at baseline, with a Cronbach α value of 0.93 for the overall scale, 0.56 for medication adherence, 0.80 for diet and physical activity, and 0.70 for safety performance. At the postintervention time point, Cronbach α values were 0.95 for the overall scale, 0.79 for medication adherence, 0.91 for diet and physical activity, and 0.89 for safety performance.

Back pain was assessed using the visual analog scale, a 10-cm line representing pain intensity from 0 to 10, with each centimeter corresponding to 1 point [19].

A process evaluation form was used to assess participants' engagement in reflective discussions after viewing the videos. Four open-ended questions were used to explore participants' experiences: (1) weekly viewing experience, (2) most preferred content and reasons, (3) least preferred content and reasons, and (4) suggestions for improving content or presentation.

Validity Testing and Tryout

The content validity of the intervention and instruments was evaluated by 5 experts in osteoporosis and physical therapy. The content validity index was 0.86, indicating good content validity. The instruments were also pilot-tested with 30 individuals with osteoporosis who met the inclusion criteria but were not enrolled in the study to assess the clarity and readability of the instruments.

Unit of Analysis

Although family members participated in the intervention sessions, outcome measures were collected only from participants with osteoporosis. Therefore, the individual participant was the unit of analysis.

Statistical Analysis

Data were analyzed using SPSS (version 29.0; IBM Corp). Normality was assessed using the Kolmogorov-Smirnov test, and all variables were normally distributed; therefore, parametric tests were applied. Baseline homogeneity between groups was examined using the chi-square test, Fisher exact test, and independent-sample *t* test as appropriate. Differences in overall self-care following the intervention were analyzed using analysis of covariance (ANCOVA), whereas differences in the 3 domains of self-care were examined using multivariate ANCOVA (MANCOVA). Statistical significance was set at $P<.05$. To facilitate transparency and reproducibility, statistical outputs from SPSS, including baseline comparisons and ANCOVA and MANCOVA results, are provided in Multimedia Appendix 2.

Prior to the main analyses, the assumptions underlying ANCOVA and MANCOVA were evaluated. Normality of residuals was assessed using the Shapiro-Wilk and Kolmogorov-Smirnov tests. The Shapiro-Wilk test indicated a slight deviation from normality ($W=0.946$; $P=.03$), whereas the Kolmogorov-Smirnov test indicated no significant departure from normality ($P=.07$). Although the Shapiro-Wilk test suggested a deviation from normality, ANCOVA and MANCOVA are considered robust to moderate violations of

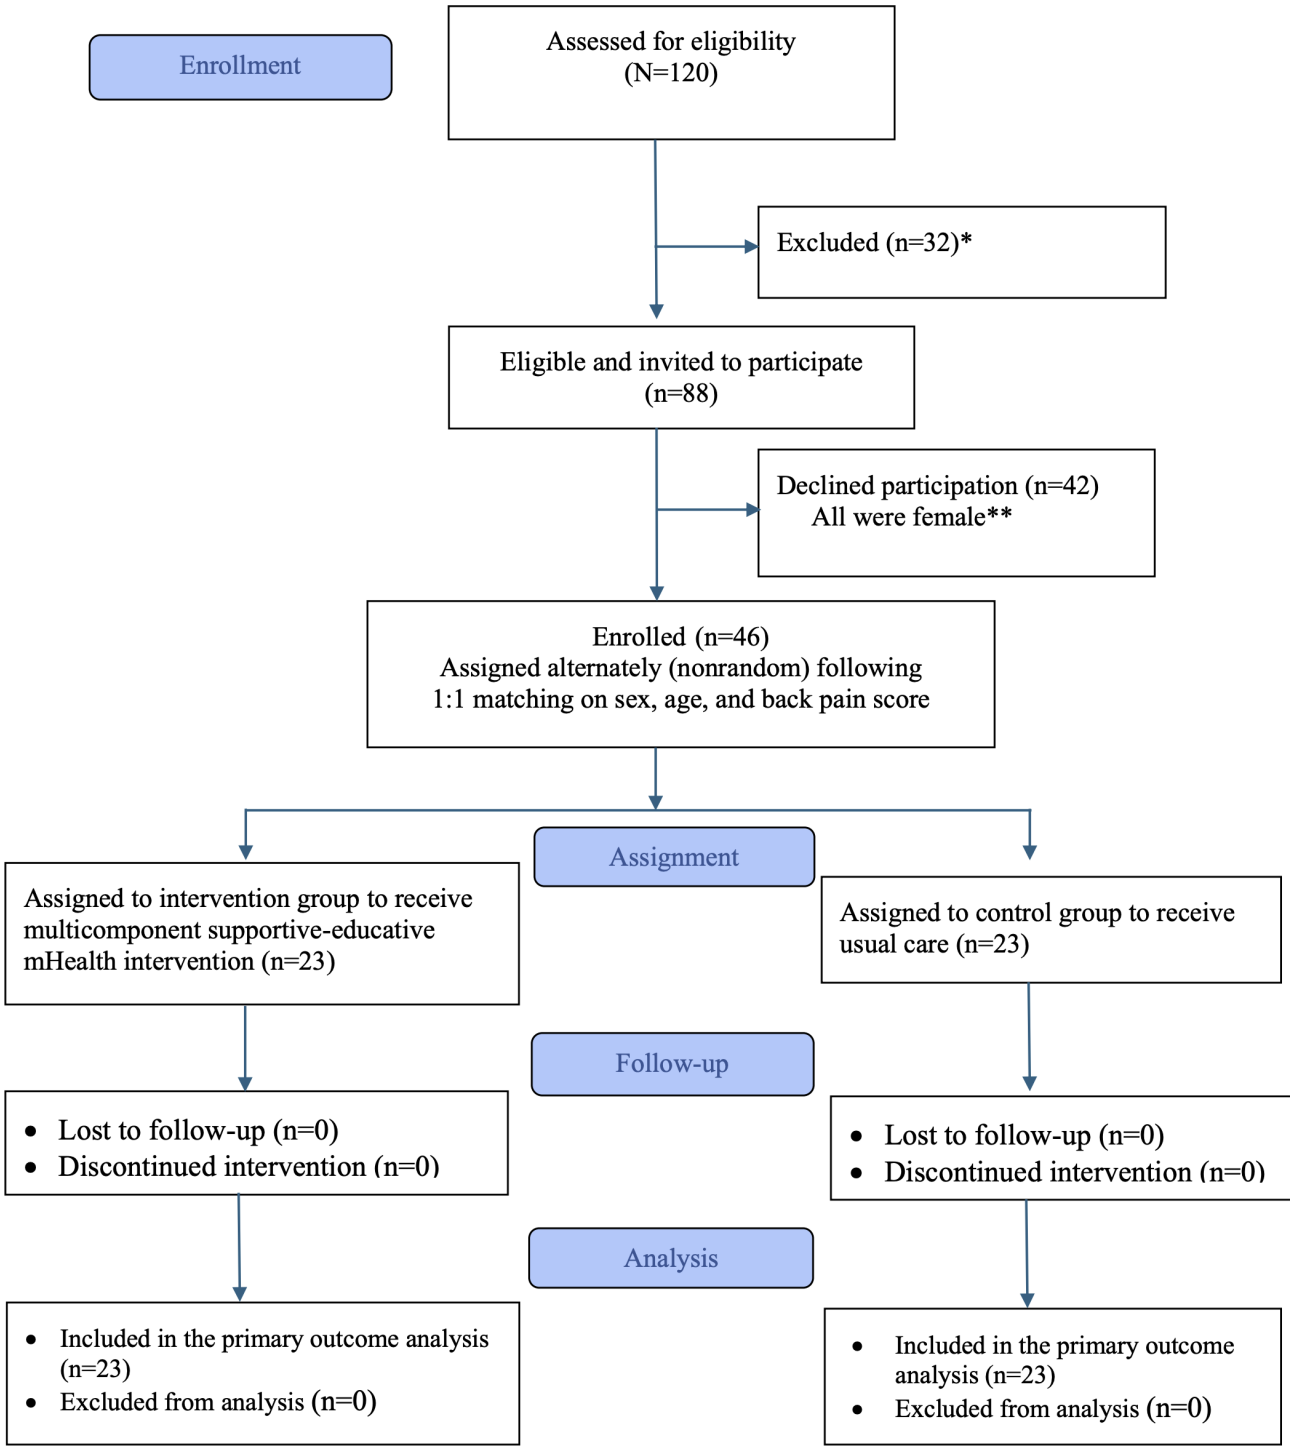
XSL•FO
RenderX

normality when group sizes are equal (n=23 per group); therefore, parametric analyses were retained. Linearity between the covariate (baseline self-care score) and the postintervention outcome was confirmed ($F_{1,43}$=113.914; P<.001). The assumption of homogeneity of regression slopes was evaluated by including a group × baseline self-care mean score interaction term in the ANCOVA model and was satisfied as the interaction was not statistically significant ($F_{1,42}$=3.626; P=.06). The Levene test indicated that the assumption of homogeneity of variance was satisfied for the overall self-care score ($F_{1,44}$=2.989; P=.09).

For MANCOVA, the Bartlett test of sphericity confirmed significant intercorrelations among the 3 self-care domains, supporting the use of a multivariate approach (χ^2_3=47.3; P<.001). Pearson correlation coefficients among the 3 postintervention domain scores ranged from 0.739 to 0.861 (P<.001 in all cases), indicating no evidence of multicollinearity (r<0.90). Homogeneity of variance-covariance matrices, assessed using the Box M test, was violated (M=21.231; F_6=3.276; P=.003). Therefore, the Pillai trace was used to evaluate multivariate group differences because it is robust to violations of the assumption of homogeneity of covariance matrices. However, the baseline mean score for the diet and physical activity domain differed significantly between the groups (P=.04), whereas the baseline mean scores for the medication adherence and safety performance domains did not. To account for this baseline difference, the corresponding baseline SCOS domain mean scores were included as covariates in the MANCOVA model. Therefore, the postintervention group comparisons were based on adjusted mean scores after controlling for the corresponding baseline SCOS domain mean scores, minimizing the potential influence of baseline imbalance on the interpretation of the between-group differences.

Ethical Considerations

Ethics approval was obtained from Chulalongkorn University (022/68) and the Faculty of Medicine of Ramathibodi Hospital (MURA2025/477). All participants provided written informed consent prior to participation. To ensure confidentiality, all data were stored in password-protected files accessible only to the research team. Participants in the intervention group received a stipend of US $8 to offset internet-related expenses associated with participation in the intervention.



Results

Homogeneity Test for Participant Characteristics

A total of 46 participants were included in the study, with 23 (50%) in the intervention group and 23 (50%) in the comparison group (Figure 1). No participants dropped out of the program. The test assessing the homogeneity of participant characteristics and dependent variable (self-care) showed no significant differences between the 2 groups, indicating that they were comparable at baseline (Table 2).

Between-Group Differences in Postintervention Self-Care

ANCOVA was conducted to compare postintervention self-care mean scores between the intervention and control groups while controlling for baseline self-care mean scores. The results showed that the intervention group had significantly higher postintervention self-care mean scores than the control group (adjusted mean difference 0.97, 95% CI 0.88-1.06; $F_{1,43}$=459.29; P<.001; partial η^2=0.914; Table 3).

MANCOVA was conducted to examine differences in the 3 domains of self-care between the intervention and comparison groups after controlling for baseline domain mean scores (medication adherence, diet and physical activity, and safety performance). The overall multivariate group difference was statistically significant, as indicated by the Pillai trace (V=0.939; $F_{3,39}$=198.45; P<.001; partial η^2=0.939), suggesting significant differences between groups for all 3 domains after controlling for baseline domain mean scores. Compared with the comparison group, the intervention group demonstrated significantly higher postintervention mean scores for diet and physical activity (adjusted mean difference 1.02, 95% CI 0.89-1.15; $F_{1,41}$=245.04; P<.001; partial η^2=0.857), safety performance (adjusted mean difference 1.04, 95% CI 0.88-1.20; $F_{1,41}$=171.20; P<.001; partial η^2=0.807), and medication adherence (adjusted mean difference 0.81, 95% CI 0.68-0.95; $F_{1,41}$=144.54; P<.001; partial η^2=0.779; Table 3).

Discussion

Main Outcomes

The findings indicate that the multicomponent supportive-educative mHealth intervention was associated with higher postintervention self-care mean scores among individuals with osteoporosis. Higher adjusted mean scores were observed across all domains of self-care (medication adherence, diet and physical activity, and safety performance), with the largest between-group difference observed for diet and physical activity.

Interpretation

The observed between-group difference may reflect the combined contribution of several intervention components. These components included the provision of clear and reliable disease-related information, weekly nurse-participant interactions, family support, sustained attention, and digital reinforcement. Disease-related knowledge may support self-care by enhancing individuals' understanding of their condition and increasing their confidence in managing it. This is consistent with the supportive-educative nursing system by Orem et al [13], which emphasizes teaching and guidance to strengthen self-care agency. In addition, the weekly nurse-participant interactions provided opportunities for participants to discuss concerns, receive feedback, and clarify misunderstandings, whereas family involvement and digital reinforcement may have strengthened self-care behaviors and sustained participants' engagement throughout the intervention.

Family support may also have played a role in these observed differences. When family members learn alongside individuals with osteoporosis, this facilitates shared review and reinforcement of the content and supports engagement in self-care. This reflects the emphasis by Orem et al [13] on providing an environment that supports personal development and self-care. Although evidence on family support intervention for osteoporosis management is limited, findings from exploratory studies suggest that family involvement may support self-care [17]. When one person misunderstands or forgets information, others can provide reminders or exchange ideas, thereby supporting sustained self-care practices. In many countries, including Thailand, extended family living and close family ties are common.

Although higher postintervention self-care mean scores were observed in the intervention group than in the control group, both groups showed increases in self-care mean scores over time. Therefore, the observed between-group differences should be interpreted cautiously as factors other than the intervention may also have influenced the findings. Participants in the control group received usual care, and repeated completion of the

XSL•FO
RenderX

self-care assessments may have increased awareness of self-care behaviors. To reduce potential confounding, participants were matched on sex, age, and back pain score, factors previously associated with self-care [6,9]. In addition, baseline self-care mean scores were controlled for in the ANCOVA and MANCOVA analyses. However, the results should be interpreted as indicating an association between the multicomponent supportive-educative mHealth intervention and higher postintervention self-care mean scores rather than as definitive evidence of a causal effect.

The multicomponent supportive-educative intervention delivered partly through Facebook provided accessible and flexible learning. Video-based content allowed for repeated viewing, whereas remote interaction with nurses enabled timely guidance and reinforcement. This continuous connection supported engagement beyond clinical settings and facilitated shared learning with family members. However, this finding contrasts with those of previous studies of app-based interventions that found no significant differences on physical activity, calcium intake, or vitamin D intake, possibly because of the lack of a personalized and interactive approach [16].

Participants' experience provides insights into how the intervention influenced self-care. Participants found dietary guidance easy to understand and reported actively implementing fall prevention strategies; in contrast, exercise was less frequently adopted. In this study, both groups reported rarely engaging in exercise before the intervention. After the intervention, however, the intervention group reported sometimes engaging in exercise, whereas the control group continued to report rarely engaging in exercise. Although exercise can increase bone mineral density, enhance muscle strength, and improve body balance, thereby reducing the risk of falls, adherence remains challenging. Previous studies have reported that exercise adherence among individuals with osteoporosis varies from 59% to 100% even when expert coaching or accessible facilities are provided [20]. These findings highlight the need for additional strategies to promote exercise adherence.

Implications for Practice and Research

This study has implications for practice. The observed between-group differences suggest that the multicomponent supportive-educative intervention delivered partly through Facebook may warrant evaluation in randomized, attention-controlled studies before clinical implementation. Nurses may consider using digital platforms to extend care beyond clinical settings and engage family members as active partners in care while recognizing that the effectiveness of this approach requires confirmation in more rigorous studies.

Limitations

This study has several limitations. As an exploratory pilot study with nonrandom allocation, the findings should be interpreted with caution because factors other than the intervention, including the unequal intensity of support between groups, may have been associated with the observed between-group differences. The substantial effect sizes should also be interpreted cautiously as the relatively small sample size and reliance on self-reported measures may have influenced the magnitude of the estimated associations. In addition, recruitment from a single hospital may limit the generalizability of the findings. The medication adherence domain demonstrated low internal consistency at baseline (Cronbach α=0.56), which may have reduced the precision of the estimated associations for this domain. Self-care was assessed using self-reported measures, which may be subject to response bias. Participants and researchers were not blinded to group assignment, and contamination between groups may have occurred because participants were recruited from the same setting. Finally, the short follow-up period did not allow for evaluation of the long-term sustainability of the observed improvements. Future studies using randomized controlled designs, larger and more diverse samples, objective measures of self-care, and longer follow-up periods are needed to confirm these findings.

Conclusions

In conclusion, the multicomponent supportive-educative mHealth intervention was associated with higher self-care mean scores across multiple domains among individuals with osteoporosis. The observed between-group differences may reflect the integration of educational content, family involvement, ongoing support, and digital delivery. However, they should be interpreted with caution given the exploratory pilot study and relatively small sample size. Further rigorous randomized controlled trials are needed to confirm the efficacy of this intervention.

Acknowledgments

The authors would like to thank the participants for their involvement in the study. The authors also express their appreciation to Professor Daniela D'Angelo, National Center for Clinical Excellence, Healthcare Quality, and Safety, Rome, Italy, for permission to use the Self-Care of Osteoporosis Scale. Generative AI (ChatGPT; OpenAI) was used for English-language editing. AI was not used in the generation of the manuscript text and tables.

Abstract

Background: Clinical handover is the process during which responsibility and accountability for care are transferred between clinicians. AI has the potential to improve the reliability and completeness of clinical handover by helping clinicians detect predefined content areas that have been communicated, identify explicit information gaps, and prompt clarification before responsibility is transferred.

Objective: This study evaluated the performance of several large language models and prompt optimization strategies for structured information extraction of synthetic nursing handover transcripts.

Methods: Two registered nurses independently annotated a dataset of 203 synthetic handover transcripts to produce consensus labels for information extraction tasks. Tasks included (1) labeling spans of text into SBAR (Situation, Background, Assessment, Recommendation) categories, (2) content detection to determine if specific pieces of information were communicated, and (3) labeling spans of text that communicated information using uncertain terms that included a subtask for identifying unknown facts. Baseline and Genetic-Pareto (GEPA)–optimized prompts were compared for the GPT-5.2, GPT-5-nano, and MedGemma 27B large language models. Additionally, the LangExtract framework was evaluated for span-extraction tasks.

Results: The GPT-5.2–optimized model achieved a micro–F_1-score of 0.85 (95% CI 0.83 - 0.88) for content detection, an absolute improvement of +0.08 compared with the matched baseline. GPT-5-nano also performed better after optimization for content detection (micro–F_1-score 0.81, 95% CI 0.78 - 0.84), suggesting that this structured task was not limited to the highest-capacity model. For SBAR span extraction, GPT-5.2 with prompt optimization achieved a micro–F_1-score of 0.76 (95% CI 0.72 - 0.79), improving by +0.24 compared with baseline and exceeding LangExtract; GPT-5-nano also improved to a micro–F_1-score of 0.69 (95% CI 0.66 - 0.72). Broad uncertainty-span extraction remained comparatively weak despite prompt optimization (micro–F_1-score 0.41, 95% CI 0.33 - 0.48; absolute improvement +0.06). In contrast, explicit unknown-fact extraction was more accurate with GPT-5.2 (micro–F_1-score 0.84, 95% CI 0.63 - 1.00), GPT-5-nano (micro–F_1-score, 0.84 95% CI 0.63 - 1.00), and MedGemma 27B (micro–F_1-score 0.80, 95% CI 0.63 - 1.00). Genetic-Pareto–optimized prompts outperformed the LangExtract approach across each span-extraction task.

Conclusions: Prompt optimization improved matched-model point estimates, with the highest performance observed for predefined content detection and SBAR span extraction. Broad uncertainty extraction remained less accurate than the narrower unknown-fact task. These technical results do not establish clinical effectiveness, safety, or readiness for real-time use. Validation using authentic nursing handover communication and prospective evaluation in clinical workflows are required before clinical application.

Introduction

Clinical handover is the process during which responsibility and accountability for some or all aspects of a patient's care are transferred to another clinician or clinical team [1]. In nursing, shift-to-shift and transfer handovers support continuity of surveillance, care priorities, pending actions, and the inclusion of patient and family concerns. Inaccurate, incomplete, or misinterpreted communication at this transition can contribute to delays, duplicated work, and preventable harm [2,3]. International and Australian patient-safety standards therefore prioritize structured clinical handover, particularly at shift changes, transfers, and discharge [1,4].

Structured handover processes aim to standardize minimum content and the format of exchange so that critical information is predictably conveyed, acted upon, and auditable. In Australia, the Communicating for Safety Standard emphasizes structured clinical handover while retaining opportunities for questions, clarification, and confirmation [1,5]. One widely used framework is SBAR (Situation, Background, Assessment, Recommendation), which organizes clinician-to-clinician handover content into 4 information categories [6]. Recent systematic review evidence suggests that structured handoff protocols may improve some safety outcomes, but the certainty and implementation fidelity vary by protocol and setting; evidence specific to SBAR remains low certainty [7].

Even where structured tools are mandated or encouraged, their enactment in nursing handovers remains shaped by ward-level organizational and cultural conditions, time demands, interruptions, and the need to communicate patient-specific information for continuity of care [8,9]. This variability is amplified in bedside nursing handover where patient/family involvement is increasingly emphasized, yet research highlights tensions between standardization (predictability) and tailoring (patient-centeredness), along with barriers related to confidentiality and clinician concerns [10,11]. Reviews of handover mnemonics similarly emphasize local validation, clarification, and readback rather than assuming that every element is universally relevant [6].

Traditional supervised information-extraction methods can be highly effective for stable tasks with sufficiently large, task-specific labeled datasets. However, there are several potential advantages of using large language models (LLMs) in this context. For example, the same instruction-driven model can be configured for heterogeneous, context-dependent tasks. This may be useful where annotated nursing handover data are limited and communication is conversational and nonlinear. Prior work has demonstrated that few-shot clinical information extraction with LLMs can be accurate, while also showing that performance depends materially on prompt design and task framing [12,13].

Recent advances in LLMs create an opportunity to support clinical handover by analyzing information as it is communicated. Other studies have examined AI-based approaches to support clinical handover, although evaluations of these technologies remain limited [14]. For example, a recent multihospital study used an LLM to pregenerate content to support the preparation for handover [15]. An alternative application of AI yet to be investigated is to support the verbal clinician-to-clinician exchange itself. This spoken exchange remains central to transferring responsibility of care in clinical settings and provides opportunities to question, clarify, and confirm information [1,9]. Accurate extraction of structured information from the spoken exchange is a prerequisite for developing this form of communication support. The aim of this study was to evaluate the accuracy of LLM structured information extraction from synthetic clinical handover transcripts.

Methods

Study Design

This study used a model-evaluation design, corresponding to the "LLM evaluation" research-design category in TRIPOD-LLM (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis–Large Language Models) [16] (Checklist 1). This category covers studies that assess existing LLMs for their accuracy or suitability for a specific health care task. We compared selected LLMs and prompt configurations on predefined multilabel classification and span-extraction tasks using completed synthetic nursing handover transcripts and registered nurse annotations. The study was not an evaluation in a health care setting because it did not test workflow integration or clinical, administrative, or workforce outcomes.

Tasks related to clinical handover communication that were considered potentially augmentable with AI assistance were identified by the researchers using a co-design process with clinicians and consumers, which will be reported separately. The tasks were as follows:

- Extracting spans of text from transcripts that aligned with the SBAR framework for structuring clinical handover. In this study, SBAR span extraction was operationalized as a sequence-labeling task to identify contiguous spans of text in handover transcripts that corresponded to each SBAR category. This task evaluated whether models could map conversational handover text to SBAR-labeled spans, rather than whether the transcripts themselves followed a clean sequential SBAR structure.
- Identifying if key elements were communicated in handover transcripts as a content detection task. In this study, this task was operationalized as a checklist of items that are recommended to be addressed during nursing clinical handover, which were developed as part of quality-improvement processes at the researchers' institution. The checklist items are summarized in Table 1.

XSL•FO
RenderX

- Identifying spans of text in transcripts that were communicated using uncertain terms. In this study, this task was operationalized as span annotation of utterances during handover that conveyed incomplete knowledge, vague or hedged wording, imprecise timing, second-hand sourcing, unclear procedures, or unclear responsibility for follow-up actions. These forms of uncertainty were treated as potentially clinically important because they may indicate information that requires clarification or verification by the receiving clinician. The uncertainty categories and example guidance provided to annotators are summarized in Table 2.

Table . Checklist items used to operationalize identification of key concepts and entities in handover transcripts.

Category	Checklist item
Patient involvement	• Clinician introductions • Introduction of clinicians to the patient or carer • Invitation for the patient or carer to participate in handover
Identification	• Verification of 3 patient identifiers
Situation	• Primary diagnosis or reason for admission • Significant events or complications • Current status, including pending tests/procedures and interim plans/orders
Background	• Relevant clinical and social history, including comorbidities • Falls risk • Pressure injury risk • Allergies • Advance care planning
Assessment	• Observations, deterioration score, and recent escalations • Pain management • Devices, lines, and vascular access • Critical monitoring and alarms • Nutrition and dietary restrictions • Fluid balance and fluid restrictions • Infusions • Medication chart review, including high-risk medicines • Pathology results or pending investigations • Mobility and use of aids • Skin integrity and related interventions
Recommendation	• Discharge plan • Critical actions required • Follow-up care plan or pathway actions • Patient or carer goals and preferences

Table . Uncertainty categories used to support annotator identification of uncertainty-related spans in handover transcripts.

Category	Definition/when to use	Example from handover speech
Hedge/probability language	The speaker indicates partial confidence or doubt about information.	“I think ENT reviewed him”; “He should be going to theatre soon.”
Vague/qualitative expression	Information is described using imprecise or subjective language.	“He looks fine now”; “Seems okay.”
Unknown fact/explicit lack of knowledge	The speaker openly states missing knowledge or incomplete data.	“Not sure if consent’s been signed”; “I don’t know his allergies.”
Indefinite timing	Timing or schedule for an event is vague or lacks precision.	“Later today”; “After the round.”
Source uncertainty	Information relies on a second-hand or unverifiable source.	“ENT said he’s on the list”; “Night nurse told me.”
Procedural uncertainty	The next step in care is unclear or the plan is not explicitly stated.	“You might want to check his IV.”
Responsibility uncertainty	A required task or follow-up is mentioned, but it is unclear who is responsible for performing it.	“Bloods to be checked later”; “Needs review this afternoon.”

Data Sources

We used the publicly available National Information and Communications Technology Australia (NICTA) Synthetic Nursing Handover Dataset, which contains synthetic recordings of clinical handovers delivered by a registered nurse based on patient profiles with cardiovascular, neurological, renal, and respiratory conditions [17]. In this dataset, handover monologs were generated from comprehensive patient profiles that included information such as the patient's name, age, admission history, inpatient duration, and the familiarity between the nurses giving and receiving the handover. The nurse was instructed to simulate a bedside shift-to-shift handover within a medical ward setting [17].

For our study, we used 100 handover samples from the training partition of the NICTA dataset. First, audio recordings from the NICTA dataset were transcribed using the OpenAI Whisper speech-to-text model. Second, 3 videos depicting conversational nursing shift-to-shift handovers were transcribed in a similar manner to provide examples of interactive handover dialogue. These videos were developed at the authors' institution for educational purposes to demonstrate best practices for clinical handovers that are used in the undergraduate nursing program. Transcripts from the educational videos were then used as few-shot examples within the DSPy framework [18] using the BootstrapFewShot optimizer to guide the transformation of the 100 NICTA monolog transcripts into 2-sided conversational handovers so that the dataset would better reflect real-world contemporary clinical handover interactions. To broaden the range of clinical contexts represented in the dataset, we further synthesized 103 additional handover examples using the GPT-5 model interactively in a chat interface. These scenarios included inter- and intrahospital transfers, postprocedural handovers, emergency department transitions, and handovers that involved patients with complex mental health care needs. The final dataset comprised 203 synthetic handover transcripts used for subsequent annotation and model development.

Ethical Considerations

Ethics approval was not sought because this was not human research as defined by the National Statement on Ethical Conduct in Human Research [19]. The study involved only synthetic handover transcripts generated for model evaluation, with no recruitment, observation, or testing of human participants, and no use of patient, clinician, clinical-record, personal, identifiable, or potentially reidentifiable data. Accordingly, the study did not require human ethics review, and a formal exemption from ethics review was not applicable.

Annotation

Two annotators, who are experienced clinically active registered nurses, independently annotated transcripts using a structured rubric. Labeled annotations that met consensus between reviewers were used as the reference labels for downstream model development and evaluation.

Annotation was performed using the Prodigy annotation software using a custom interface that presented each transcript in 3 components [20]. First, annotators highlighted relevant spans of text and assigned labels corresponding to the SBAR framework together with markers of communicative uncertainty, including vagueness, hedging, unknown facts, indefinite timing, source uncertainty, procedural uncertainty, and uncertainty regarding responsibility. Overlapping span labels were permitted where a passage served more than 1 communicative function. Second, annotators completed a multiple-response checklist indicating whether predefined handover elements were present in the transcript.

Both annotators reviewed all transcripts independently within the same annotation environment and were supported by written guidance and examples to promote consistent interpretation of the coding framework. For the creation of the reference standard, a consensus dataset was derived by retaining only those span annotations and checklist items for which both annotators agreed. In practical terms, this meant that only text segments assigned the same label by both reviewers, and only checklist items selected by both reviewers, were carried forward for downstream model development and evaluation.

LLM Prompt Optimization Methods

Annotated handover transcripts were first partitioned deterministically into optimization (75%) and evaluation (25%) subsets using a fixed random split. Prompt optimization was performed within DSPy [18], which is a Python framework that can be used for prompt optimization using feedback from model outputs to improve task performance. For each task, we defined a task-specific DSPy signature that specified the transcript as input and a constrained structured output. Checklist prediction was formulated as multilabel classification, where the task was to return a list of the items from the checklist that were covered in the transcript. The SBAR and uncertainty-related tasks were formulated as span extraction requiring the model to return verbatim text segments from the transcript together with the appropriate label. The uncertainty-related tasks were further subdivided into a broad uncertainty-span extraction task (which included all uncertainty categories) and a more specific unknown-fact extraction task (which included only spans labeled as unknown facts).

Across the baseline DSPy evaluations, Genetic-Pareto (GEPA)–based DSPy optimization experiments, and LangExtract experiments, we purposively selected 3 underlying language models with different deployment profiles: OpenAI GPT-5.2 as the higher-capacity proprietary model, OpenAI GPT-5-nano as a smaller lower-cost proprietary model [21], and MedGemma 27B as a 27-billion-parameter open-weight model developed for medical tasks [22]. This panel was intended to examine matched prompt effects across contrasting model profiles, not to provide an exhaustive leaderboard of all contemporary LLMs. For DSPy baseline and GEPA runs, the same task model was used before and after optimization so that differences reflected the prompt configuration rather than a change in the underlying model. GPT-5.2 and GPT-5-nano were accessed through cloud-hosted OpenAI API end points; MedGemma 27B was run locally on institutional high-performance computing infrastructure.

GEPA was used to optimize the task prompts [23]. It iteratively evaluated candidate task instructions, combined numeric task scores with natural-language error feedback, and used GPT-5.2

XSL•FO
RenderX

as a separate reflection model to propose revisions. Optimization used 576 scoring calls. Checklist optimization targeted multilabel agreement, while span-task optimization rewarded same-label text overlap using intersection over union (IoU) so that closer boundaries received higher scores. A transcript with neither a reference span nor a predicted span for a target label was treated as a correct negative. The final compiled prompts were fixed before evaluation on the held-out partition. For reporting, span detection performance and boundary overlap were presented separately.

In addition to DSPy prompt optimizations, we conducted separate evaluations using the LangExtract framework, as a prompt-based few-shot structured information extraction approach for the SBAR, uncertainty-span, and unknown-fact span tasks [24]. These experiments used task-specific prompt descriptions together with annotated in-context examples derived from the reference data. We used 10 annotated examples from the training partition as few-shot exemplars, and inference was then performed on the full held-out test partition for each task.

Data Analysis

Interrater agreement was assessed with Cohen κ and mean IoU among matched spans. Agreement CIs were calculated with 2000 bootstrap resamples of transcript pairs using a fixed random seed.

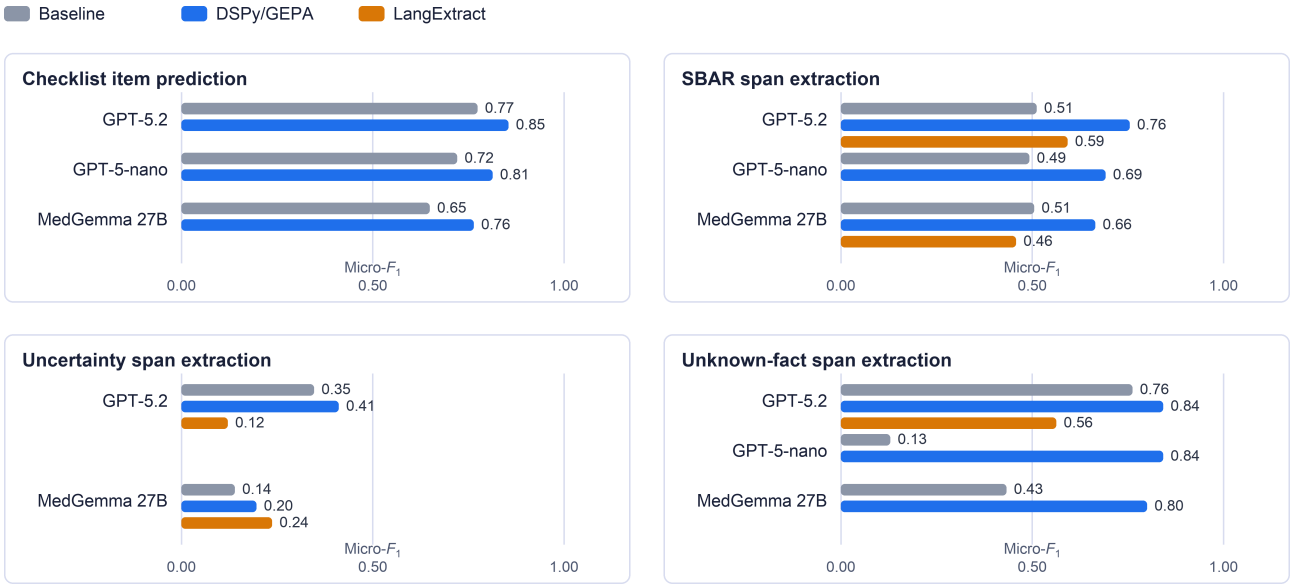
Performance was measured for the checklist content detection task at the level of individual labels with counts of true positives, false positives, false negatives, and true negatives, together with precision, recall, and F_1-score. Aggregate performance was summarized using micro-averaged (pooled), macro-averaged (unweighted mean), and support-weighted precision, recall, and F_1-score across labels.

For span-extraction tasks, precision, recall, and F_1-score were calculated from predicted spans as binary detection measures, so that these statistics reflected the model's ability to identify the correct labeled spans. Span-boundary agreement was reported separately using the mean IoU across matched pairs. We additionally calculated per-label descriptive metrics including the number of reference spans, the number of predicted spans, matched-span precision, recall, F_1-score, and mean IoU.

Sampling uncertainty was summarized with 95% CIs calculated using nonparametric bootstrap resampling. For each result, we resampled transcripts with replacement 2000 times using a fixed random seed and recalculated the relevant metric from the pooled counts in each resample. Confidence limits are reported as the 2.5th and 97.5th percentiles of the bootstrap distribution.

Results

Preconsensus Interrater Agreement



Cohen κ was 0.75 (95% CI 0.73 - 0.76) for checklist decisions, 0.70 (95% CI 0.68 - 0.72) for pooled SBAR token-by-label decisions, 0.12 (95% CI 0.08 - 0.15) for broad uncertainty, and 0.40 (95% CI 0.18 - 0.64) for unknown facts. Among overlapping same-label spans, the mean IoU was 0.86 (95% CI 0.85 - 0.87) for SBAR, 0.71 (95% CI 0.61 - 0.81) for broad uncertainty, and 0.78 (95% CI 0.56 - 0.98) for unknown facts. The relatively high matched-span IoU indicates similar boundaries when both nurses identified the same span type, with disagreement in uncertainty annotations arising mainly over whether and how to label an expression.

Key Findings

Within-model comparisons showed consistent point-estimate gains with DSPy/GEPA over matched unoptimized-prompt baselines. For GPT-5.2, micro–F_1-score increased from 0.77 (95% CI 0.74 - 0.80) to 0.85 (95% CI 0.83 - 0.88) for checklist prediction, from 0.51 (95% CI 0.47 - 0.55) to 0.76 (95% CI 0.72 - 0.79) for SBAR span extraction, from 0.35 (95% CI 0.28 - 0.41) to 0.41 (95% CI 0.33 - 0.48) for uncertainty span extraction, and from 0.76 (95% CI 0.50 - 1.00) to 0.84 (95% CI 0.63 - 1.00) for unknown-fact extraction. Across span tasks, LangExtract generally had lower point estimates than the corresponding highest DSPy/GEPA configuration. Among matched span predictions, the mean IoU exceeded 0.8 for the highest-performing GPT-5.2 span-extraction configurations. Figure 1 summarizes matched within-model comparisons across tasks for the 3 evaluated models.

Figure 1. Micro–F_1-scores for baseline, Genetic-Pareto (GEPA)–optimized, and LangExtract strategies for each model within each task.

SBAR Span Extraction

Among SBAR configurations, the highest overall score was achieved by DSPy/GEPA-optimized GPT-5.2 (micro–F_1-score 0.76, 95% CI 0.72 - 0.79), followed by DSPy/GEPA-optimized GPT-5-nano (micro–F_1-score 0.69, 95% CI 0.66 - 0.72) and LangExtract GPT-5.2 (micro–F_1-score 0.59, 95% CI 0.56 - 0.62). Table 3 provides label-level results for the best-performing GPT-5.2 DSPy/GEPA SBAR configuration.

Table . Per-label SBAR (Situation, Background, Assessment, Recommendation) metrics for the best-performing GPT-5.2 DSPy/Genetic-Pareto (GEPA) model.

Label	Reference spans	Predicted spans[a]	Recall (95% CI)	Precision (95% CI)	Mean IoU[b] (95% CI)	F_1-score (95% CI)
ASSESSMENT	194	192	0.77 (0.72 - 0.82)	0.78 (0.72 - 0.83)	0.77 (0.72 - 0.81)	0.77 (0.73 - 0.81)
BACKGROUND	47	50	0.72 (0.61 - 0.84)	0.68 (0.57 - 0.79)	0.66 (0.56 - 0.75)	0.70 (0.60 - 0.80)
RECOMMENDATION	113	124	0.76 (0.69 - 0.84)	0.69 (0.62 - 0.78)	0.78 (0.73 - 0.83)	0.73 (0.67 - 0.78)
SITUATION	73	52	0.68 (0.57 - 0.81)	0.96 (0.88 - 1.00)	0.82 (0.75 - 0.88)	0.80 (0.72 - 0.89)

[a]Predicted spans: model-generated spans mapped back to the transcript.

[b]IoU: intersection over union for matched span boundaries.

Within this GPT-5.2 SBAR comparison, macro-precision increased from 0.41 (95% CI 0.37 - 0.44) to 0.78 (95% CI 0.73 - 0.82), macro-recall from 0.69 (95% CI 0.63 - 0.75) to 0.73 (95% CI 0.69 - 0.78), and macro–F_1-score from 0.49 (95% CI 0.46 - 0.53) to 0.75 (95% CI 0.71 - 0.79). Span-boundary agreement among matched predictions was strongest for SITUATION and RECOMMENDATION, as shown by the label-level mean IoU estimates in Table 3.

Checklist Task

For checklist prediction, the best overall result was achieved by DSPy/GEPA-optimized GPT-5.2 (micro–F_1-score 0.85, 95% CI 0.83 - 0.88; macro–F_1-score 0.73, 95% CI 0.63 - 0.76; and support-weighted F_1-score 0.85, 95% CI 0.82 - 0.88). DSPy/GEPA-optimized GPT-5-nano also performed competitively (micro–F_1-score 0.81, 95% CI 0.78 - 0.84), while MedGemma 27B reached a micro–F_1-score of 0.76 (95% CI 0.74 - 0.79). Tables 4 and 5 present grouped per-label estimates for accuracy, precision, recall, and F_1-score for the best-performing GPT-5.2 checklist model.

Invitation for patient/carer to participate in handover	0.82 (0.69 - 0.92)	0.65 (0.44 - 0.83)	0.94 (0.78 - 1.00)	0.77 (0.59 - 0.89)

[a]95% CIs are not provided for labels with few positive examples in the test set.

[b]Accuracy: (true positives + true negatives)/all evaluated transcripts for that checklist item.

Uncertainty and Unknown-Fact Span Extraction

Broad uncertainty-span extraction included all annotated uncertainty categories (hedging, vagueness, unknown facts, indefinite timing, source uncertainty, procedural uncertainty, and responsibility uncertainty) and had the lowest micro–F_1-score of the evaluated tasks. The highest DSPy/GEPA point estimate used GPT-5.2 and achieved a precision of 0.32 (95% CI 0.26 - 0.39), a recall of 0.56 (95% CI 0.44 - 0.67), a micro–F_1-score of 0.41 (95% CI 0.33 - 0.48), and a mean IoU of 0.83 (95% CI 0.77 - 0.90). The highest unoptimized-prompt baseline had a micro–F_1-score of 0.35 (95% CI 0.28 - 0.41), and the highest LangExtract uncertainty result had a micro–F_1-score of 0.24 (95% CI 0.17 - 0.31).

The narrower unknown-fact subtask had higher point estimates. DSPy/GEPA reached a micro–F_1-score of 0.84 (95% CI 0.63 - 1.00) with GPT-5.2, compared with the highest baseline micro–F_1-score of 0.76 (95% CI 0.50 - 1.00) and the LangExtract GPT-5.2 micro–F_1-score of 0.56 (95% CI 0.29 - 0.72). These results concern explicitly stated lack of knowledge, not facts absent from the transcript. Table 6 summarizes the uncertainty and unknown-fact span results used for these comparisons.

[a]IoU: intersection over union for matched span boundaries.

[b]DSPy: framework for declarative language model programming.

[c]GEPA: Genetic-Pareto.

Discussion

Principal Results

This study identified that prompt optimization with GEPA outperformed baseline evaluations across all of the comparisons, with higher aggregate performance for checklist prediction than for SBAR span extraction. This pattern is expected because using generative AI to perform clinical natural language processing tasks is sensitive to framing, label definitions, and example selection. GEPA was explicitly supplied with task-specific scores and error feedback that could align instructions more closely with the annotation scheme [13,23]. Optimization was particularly useful for improving targeted span extraction across the SBAR task.

The difference in accuracy that we identified between checklist prediction and SBAR span extraction provides an important insight to consider for designing AI applications to support clinical handover. Checklist prediction is a simpler structured-output task where each item is a bounded present/absent judgment. By contrast, SBAR extraction requires the model to locate clinically relevant text, assign a communicative category, and reproduce appropriate span boundaries. Structured handover tools aim to make minimum content predictable and reduce omissions, while still requiring adaptation to local clinical workflow [25-27]. As such, bounded present/absent outputs may be useful when the intended function is to prompt review of missing elements or support audit and quality monitoring. It is fortunate, then, that the task with the strongest performance in our study was the one most closely aligned with a recurring mechanism of handover-related harm, namely omitted or incomplete information [2,26,28]. Although checklist prediction achieved high accuracy, the consequences of both false positives and false negatives should be considered. A false negative would usually create review burden by prompting clarification of an item that was already communicated, but a false positive could create more serious false reassurance that a safety-critical element was conveyed when it was not. In addition, a checklist item not detected in the captured transcript is not equivalent to clinically necessary information having been omitted. A safer near-term design could therefore present AI outputs as source-linked prompts for clinician review, with clear distinctions between detected in transcript, not detected, and requires verification. Evidence has indicated that effective clinical decision support is most useful when integrated into a workflow as actionable and readily available support at the time and place of decision-making, while also recognizing the risk of automation bias when clinicians overrely on system outputs [29-31].

Registered nurse annotation agreement was comparatively high for checklist and SBAR annotations but very low for the broad uncertainty taxonomy. The latter finding indicates that vague, hedged, or context-dependent communication was difficult to operationalize consistently even with written guidance. However, the combination of low κ and relatively high matched IoU scores for broad uncertainty indicates that the principal difficulty was deciding whether uncertainty was present, rather than locating its boundaries once identified. As all model optimization and evaluation used the final consensus ratings between annotators, the results should therefore be interpreted as being conservative.

This study did not compare LLMs with non–LLM-based methods of structured information extraction. It therefore provides evidence about relative prompt optimization approaches and model configurations, not the superiority of LLMs over conventional information extraction. Nevertheless, evaluating LLM-based approaches is a logical next step in this handover-specific research program. In the original NICTA benchmark, a feature-engineered conditional random field achieved a macro–F_1-score of 0.702 across 35 handover-form categories, but performance was markedly uneven. F_1-score was 0.217 for the more abstract "other observations" category and 0.496 for future-care goals, tasks, and expected outcomes, and the error analysis identified clinically relevant missed and misclassified information [17]. These limitations were concentrated in categories requiring greater contextual differentiation. Instruction-tuned LLMs therefore warranted evaluation as a potentially more flexible approach to context-dependent handover information, particularly where prompt optimization can adapt extraction behavior using a modest labeled set.

The optimized SBAR extraction model achieved high span-boundary overlap among matched spans in our study. It should be considered, though, that SBAR is an idealized communication framework, while real clinical handovers often move nonlinearly, revisit information, distribute relevant details across the conversation, or place content between categories. For implementation, this suggests that extracted spans could be displayed with a link to their source transcript context and should support clinician review of what was said, rather than automatically transforming the handover into a definitive structured note. This preserves the benefits of structured communication while avoiding over-compression of clinically meaningful narrative context [25,32,33].

Implementation Considerations

The appropriate balance between recall and precision may differ by use case when considering the implementation of the tasks we evaluated in this study into an AI tool to support clinical handover. For real-time clinician support, the intervention should be framed as shaping safe handover dialogue rather than only producing a structured output after the exchange has ended. Higher recall may be appropriate where the system displays nondetected checklist items under an "Items to check" heading and allows the receiving clinician to mark each item as addressed, not relevant, or requiring clarification. This presentation would avoid implying that the information was definitely omitted while supporting clarification before responsibility transfers. For retrospective audit or compliance monitoring, precision becomes more important because false positives could overestimate handover quality and obscure residual safety risks. The present checklist results, with high recall but nontrivial false positives in several categories, therefore support cautious separation of 2 implementation pathways: real-time clinician-facing gap prompts and separately validated audit/reporting workflows [28,29,34].

Gold standard handovers include active verification and shared situational awareness rather than passive transfer of uncertain information [33,35-37]. Evaluation results of the broad uncertainty-span performance indicate that even a GEPA-optimized prompt with a state-of-the-art proprietary LLM is not yet reliable for detecting the full range of ambiguous, hedged, or context-dependent communication. This should be interpreted against the clinical reality that uncertainty is also difficult for humans to recognize and act on consistently, particularly under time pressure or when concern is communicated indirectly. Many forms of clinically important uncertainty are implicit and embedded in shared team understanding: phrases such as "he seems off today" or "not quite themself" can convey concern through context, trajectory, and prior knowledge rather than through explicit wording that a model can reliably extract. By contrast, the comparatively more accurate unknown-fact extraction results suggest a potentially useful role for identifying explicit information gaps that can be converted into clarification prompts for the receiving clinician. As foundation models continue to improve, accuracy on this task may also improve, although reliable use in safety-critical handover settings will still require ongoing empirical validation.

Relatedly, it is highly likely that further gains could be realized after implementation independent of general improvements in underlying LLM capability. If clinicians review AI-generated handover outputs and corrections are retained as labeled examples, subsequent optimization cycles using the same GEPA prompt optimization pipeline we used in this study would plausibly improve performance over time. Prior clinical natural language processing active-learning studies have demonstrated that selectively labeled examples can improve data efficiency for both clinical text classification and clinical named-entity recognition [38,39]. In practice, any such learning cycle should be treated as a controlled quality-improvement process, with monitoring and re-evaluation before revised prompts or models are released into clinical use [40].

Finally, it should be noted that this study measured extraction and classification performance against annotated labels but did not evaluate whether AI outputs changed clinician questioning, closed-loop communication, task completion, escalation, near-miss detection, or patient outcomes. Technical metrics are necessary but insufficient for determining whether a clinical AI tool improves safety in practice [31,37,41]. Recent commentary and discursive work on nursing automation similarly argue that evaluation should move beyond time saved to examine how AI redistributes nursing work toward review and verification, whether tools meet end user–defined use thresholds, whether performance is equitable across linguistic and workforce groups,

XSL•FO
RenderX

and how automation can be integrated without undermining professional values or relational care [42,43]. Even accurate prompts may create new risks if clinicians overtrust them, ignore nonhighlighted issues, experience alert fatigue, or redirect attention away from direct patient/carer engagement. Human factors testing should therefore assess reliance, trust calibration, interruption burden, and the usability of source-linked evidence before deployment [30,36,44].

Limitations

The synthetic conversational handovers used in this study may not fully represent those performed in actual clinical practice where interruptions, time pressure, environmental noise, nonverbal cues, and local team dynamics can affect what is communicated and how it is interpreted. External validation on real handover audio/transcripts from intended deployment settings is therefore required [33,35,44]. External validity may be particularly limited for complex areas such as mental health, multimorbidity, and other contexts where clinical risk is often communicated through narrative nuance, formulation, behavioral change, staff concern, or tone of interaction rather than discrete data points. These contexts strengthen the need for AI outputs to remain clinician-reviewed, source-linked supports rather than autonomous clinical documentation.

It should be noted that several checklist items had low prevalence in the evaluation partition. Future evaluation should oversample or otherwise specifically test these items [26,31]. Furthermore, the reference standard retained only annotations agreed by both reviewers. This creates a conservative and reproducible benchmark but may exclude ambiguous or contested communication.

The evaluation corpus included synthetic transcripts generated in part with GPT-5. Although the uses were distinct, information extraction tasks were performed on synthesized language from a model from the same LLM provider, which is potentially susceptible to model familiarity. Synthetic transcripts may also be more predictable than authentic handover communication. In addition, the highest-performing models evaluated in this study were hosted proprietary systems that are updated and managed externally. Model updates, infrastructure variability, or configuration changes could alter performance over time in ways that are not fully transparent or controllable, with implications for reproducibility, governance, and consistency in clinical settings where reliability is critical. Locally hosted models may offer greater control over model versioning and deployment conditions but can require substantial compute and may be less responsive to rapid improvements in frontier model capability.

Our evaluation focused on downstream extraction from transcripts and did not separately quantify transcription accuracy, speaker attribution, or the effect of noisy audio. In a real-time handover system, errors introduced before the LLM stage could alter checklist detection, SBAR span extraction, and uncertainty identification. End-to-end evaluation should therefore include audio capture, transcription, diarization, and transcript-to-output performance under realistic clinical conditions [2,44]. We used a checklist that was developed at a local institution based on local priorities for communication during clinical nursing handover. Other wards, specialties, transfer types, or jurisdictions may prioritize different minimum datasets or use different terminology. Implementation would therefore require local mapping of labels to existing handover policy, audit tools, escalation pathways, and documentation workflows, followed by local validation rather than direct transfer of the reported performance estimates [26,34,44].

Conclusions

In this evaluation of AI-assisted clinical handover tasks, prompt optimization consistently improved matched model performance. Accuracy was the highest for bounded checklist prediction and SBAR span extraction. Broad uncertainty detection remained insufficiently reliable, while explicit unknown-fact extraction suggests a narrower but important role for prompting clarification when missing knowledge is directly expressed. Before clinical deployment, these approaches require external validation on real handover audio and transcripts; end-to-end testing of transcription and diarization effects; local calibration of checklist definitions, human-factors evaluation of trust, reliance, workflow burden, and downstream safety outcomes; and structured assessment of organizational readiness for AI implementation in nursing care [45].

Abstract

Background: The rapid integration of generative AI (GenAI) into nursing education has prompted widespread concern about academic integrity and assessment validity. However, this dominant discourse may obscure a more fundamental challenge: preparing nursing students for clinical practice environments where AI already mediates triage, diagnostics, documentation, and clinical decision-making.

Objective: This integrative review examines how GenAI is conceptualized within the nursing education literature and investigates the extent to which current discourse addresses professional formation rather than academic compliance.

Methods: Following Whittemore and Knafl's integrative review methodology, a systematic search of PubMed, Google Scholar, and SciSpace (Typeset) was conducted for literature published between January 2022 and February 2026. Two reviewers independently screened 456 records, with 119 papers meeting the inclusion criteria. The methodological quality of empirical studies was assessed using the Mixed Methods Appraisal Tool (MMAT). Corpus-level descriptive mapping quantified dominant themes and conceptual patterns, while an interpretive synthesis examined how GenAI was framed and the extent to which professional formation elements, including identity, moral agency, and clinical judgment, were addressed.

Results: Of the 119 unique studies analyzed, 84% (n=100) predominantly framed GenAI as a content-generation tool and academic integrity threat. Only 35.3% (n=42) conceptualized AI as a pedagogical tool, and a critical gap was identified in professional formation: identity formation was addressed in only 10% (n=12) of papers and moral agency in just 5% (n=6). Explicit acknowledgment that AI already routinely mediates frontline clinical decisions (eg, sepsis alerts and fall risk algorithms) in current practice settings was notably absent. The discourse emphasizes governance and faculty literacy, but sustained curricula addressing nurse identity in AI-mediated care remain underdeveloped.

Conclusions: Current nursing education discourse predominantly frames AI as a writing tool and an academic integrity concern, failing to prepare students for the algorithmic practice environments they will inhabit. Nursing education must reframe AI as a professional formation issue, explicitly addressing how algorithms reshape clinical judgment, moral agency, and professional identity.

(JMIR Nursing 2026;9:e99284) doi:10.2196/99284

KEYWORDS

AI; generative AI; nursing education; professional formation; academic integrity; clinical judgment; algorithmic practice; student identity

Introduction

The rapid emergence of generative AI (GenAI), particularly large language models such as ChatGPT (OpenAI), has prompted one of the most significant pedagogical disruptions experienced by higher education in recent decades. Since ChatGPT became publicly available in late 2022, nurse educators have grappled with questions surrounding academic integrity, assessment validity, authorship, and the appropriate boundaries of AI use in student learning [1,2]. These concerns have generated a rapidly expanding body of literature examining the educational implications of GenAI and have prompted widespread institutional responses, including revised assessment practices, AI policies, and faculty development initiatives [3-5].

Alongside these educational developments, health care itself is undergoing rapid technological transformation. AI is increasingly embedded within contemporary clinical practice through technologies such as clinical decision support systems, predictive analytics, automated documentation, risk stratification algorithms, and workflow optimization tools. Unlike GenAI, which generates novel content in response to user prompts, clinical decision support systems primarily support clinicians' decision-making using predefined rules, predictive models, or

XSL•FO
RenderX

machine learning algorithms embedded within health care workflows [6,7]. Consequently, graduates entering the nursing workforce will not simply encounter AI as an educational technology but will practice within health care environments where algorithmic systems increasingly influence clinical reasoning, decision-making, and patient care. Preparing nurses for this reality requires educational approaches that extend beyond managing AI use during assessment to considering how future practitioners develop professional judgment, ethical reasoning, and accountability within algorithmically mediated practice.

Recent reviews have made important contributions to understanding GenAI in nursing education by examining issues such as academic integrity, ethical considerations, educational applications, faculty preparedness, student perceptions, and pedagogical innovation [3,8-11]. Collectively, this work has established a valuable evidence base describing how GenAI is being adopted, the opportunities it presents, and the challenges it poses for teaching and learning. However, these reviews have largely conceptualized AI as an educational tool or educational problem. Comparatively little attention has been directed toward how the literature frames the broader educational purpose of preparing nurses for professional practice in health care systems where AI is already integrated into routine clinical care.

This distinction is important because educational discourse is not neutral. The ways in which emerging technologies are framed influence curriculum priorities, assessment practices, faculty development, and ultimately the capabilities that nursing programs seek to cultivate. When AI is positioned primarily as a threat to academic integrity, educational responses naturally focus on governance, surveillance, and assessment redesign. While these responses are appropriate and necessary, they risk narrowing the educational conversation by privileging academic compliance over the broader question of professional formation. Understanding how the literature conceptualizes the educational challenge posed by GenAI is therefore essential, as these conceptualizations shape what is valued, taught, and assessed within nursing education.

Professional identity formation provides a useful theoretical lens through which to examine this issue. Professional identity formation describes the developmental process through which learners progressively integrate the values, behaviors, knowledge, and responsibilities of the profession into their sense of self, ultimately learning to “think, act, and feel” like nurses [12,13]. In nursing, this process encompasses the development of clinical judgment, ethical reasoning, patient advocacy, relational care, accountability, and moral agency [14]. As AI becomes increasingly embedded within health care delivery, the contexts in which professional identity develops are also changing. Consequently, understanding how nursing education conceptualizes AI extends beyond questions of technology adoption to encompass how future nurses are prepared to exercise judgment, maintain professional responsibility, and provide person-centered care alongside increasingly sophisticated algorithmic systems.

Against this background, this review adopts a different perspective from previous syntheses. Rather than asking how GenAI is being used in nursing education or whether its use should be encouraged or restricted, this review examines how the nursing education literature conceptualizes the educational challenge itself. Specifically, it explores whether contemporary discourse remains predominantly centered on academic integrity and educational governance or whether it also addresses professional formation for algorithmically mediated clinical practice.

The review was guided by the following research question: how is GenAI conceptualized within the nursing education literature and to what extent does the current discourse address professional formation?

Professional identity formation therefore served as the conceptual lens underpinning the review, informing both the analysis of the literature and the interpretation of how nursing education currently positions students as future professionals within increasingly AI-enabled health care environments.

Methods

Design

This study used an integrative review methodology guided by Whittemore and Knafl’s [15] framework, which supports the systematic synthesis of diverse forms of evidence, including empirical research, reviews, theoretical papers, commentaries, editorials, and professional guidance documents. This approach was selected because scholarship related to GenAI in nursing education remains methodologically heterogeneous and conceptually emergent, making conventional systematic review approaches that focus exclusively on empirical effectiveness studies insufficient to address the research question.

Unlike reviews designed to evaluate intervention effectiveness, this review sought to examine how GenAI is conceptualized across contemporary nursing education literature. Accordingly, the review combined systematic literature identification with qualitative interpretive synthesis to explore the dominant narratives, assumptions, and conceptual framings underpinning current scholarship.

Conceptual Orientation

Professional identity formation served as the conceptual lens underpinning the review. Rather than cataloging educational applications of GenAI, this review examined how nursing education scholarship constructs the educational challenges associated with AI and the extent to which these constructions address preparation for algorithmically mediated clinical practice.

This orientation recognizes that literature not only reports evidence but also shapes professional priorities by privileging particular educational concerns while rendering others less visible. Consequently, the review adopted a discourse-oriented approach, seeking to identify both dominant conceptual framings and important conceptual absences within the literature.

Search Strategy

A systematic literature search was undertaken to identify publications examining GenAI within nursing education.

XSL•FO
RenderX

Searches were conducted across PubMed, Google Scholar, and SciSpace (Typeset), capturing literature published between January 1, 2022, and February 28, 2026. The search period commenced immediately prior to the public release of ChatGPT to capture the emergence of contemporary GenAI scholarship.

The database selection reflected complementary strengths. PubMed was selected because it comprehensively indexes biomedical and health professions literature. Google Scholar provides broad scholarly coverage across disciplines, while SciSpace facilitates the retrieval of recently published and emerging AI-related scholarship in this rapidly evolving field.

The search terms combined controlled vocabulary (where available) and keywords relating to GenAI, nursing education, and professional formation. Boolean operators were used to combine concepts, with database-specific adaptations applied as required. The complete search strategies for all databases are presented in Multimedia Appendix 1.

Following database searches, the reference lists of included reviews and key papers were manually examined to identify additional eligible studies not retrieved through electronic searches. Textbox 1 summarizes the eligibility criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Papers addressing generative AI in nursing education contexts
- Published or preprinted between 2022 and 2026
- Focus on undergraduate or graduate nursing education
- Empirical studies, theoretical papers, position statements, or reviews

Exclusion criteria:

- Papers focusing solely on nongenerative AI (eg, predictive analytics and diagnostic imaging AI)
- Papers addressing AI in clinical practice without educational implications
- Conference abstracts without full text
- Duplicate publications

Study Selection

All search results were imported into a reference management program, and duplicate records were removed prior to screening.

Study selection followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 framework (Checklist 1). Titles and abstracts were independently screened by 2 reviewers against the predefined eligibility criteria. Potentially eligible studies subsequently underwent full-text assessment.

Disagreements at either stage were resolved through discussion until consensus was reached. Where uncertainty remained regarding eligibility, studies were retained for full-text review to maximize sensitivity during screening.

The study selection process is presented in the PRISMA flow diagram in the *Results* section.

Quality Appraisal

Methodological quality was assessed for all empirical studies using the Mixed Methods Appraisal Tool (MMAT), which allows consistent appraisal across qualitative, quantitative, and mixed methods research designs.

Because this review also included reviews, theoretical papers, editorials, and professional commentaries, these publications were appraised according to their conceptual relevance, clarity of argument, and contribution to the understanding of GenAI within nursing education rather than being evaluated with empirical quality criteria.

Consistent with integrative review methodology, studies were not excluded on the basis of methodological quality. Instead, quality appraisal informed the interpretation of the findings by providing greater weight to higher-quality empirical evidence while recognizing the important conceptual contributions of theoretical literature.

Data Extraction

A structured data extraction framework was developed prior to the analysis and was applied consistently across all included publications.

For each study, the following information was extracted: bibliographic details, year of publication, country of origin, publication type, study design, educational context, primary focus of the AI application, principal findings, and relevance to professional formation.

To support the review's conceptual focus, each paper was additionally coded for the presence or absence of 7 predefined professional formation constructs derived from the literature. Coding was based on explicit discussion of each construct within the publication. Where constructs were not directly named, studies were coded as present only when the underlying concept was clearly described or operationalized in relation to nursing education. The predefined professional formation constructs

XSL•FO
RenderX

comprised professional identity formation, ethical reasoning, moral agency, clinical judgment, digital professionalism, algorithmic bias and power awareness, and preparation for algorithmically mediated clinical practice.

Studies were further coded according to publication characteristics, dominant AI framing, educational focus, and the presence of the predefined professional formation constructs. Descriptive coding captured publication characteristics and educational context, while conceptual coding identified how GenAI was framed within the literature and whether professional formation constructs were explicitly or implicitly represented. Coding categories were initially informed deductively by the professional identity formation literature and subsequently refined through iterative familiarization and engagement with the corpus.

The complete extraction framework is presented in Multimedia Appendix 2.

Data Analysis

Analysis occurred in 2 complementary phases.

Phase 1: Corpus-Level Descriptive Mapping

The first phase involved corpus-level descriptive mapping across all included publications.

Descriptive analyses quantified publication trends, dominant conceptualizations of GenAI, and the frequency with which professional formation constructs appeared across the literature. These analyses provided an overview of the prevailing discourse within contemporary nursing education scholarship.

Phase 2: Interpretive Synthesis

The second phase used interpretive synthesis to examine how the identified patterns collectively constructed the discourse surrounding GenAI within nursing education.

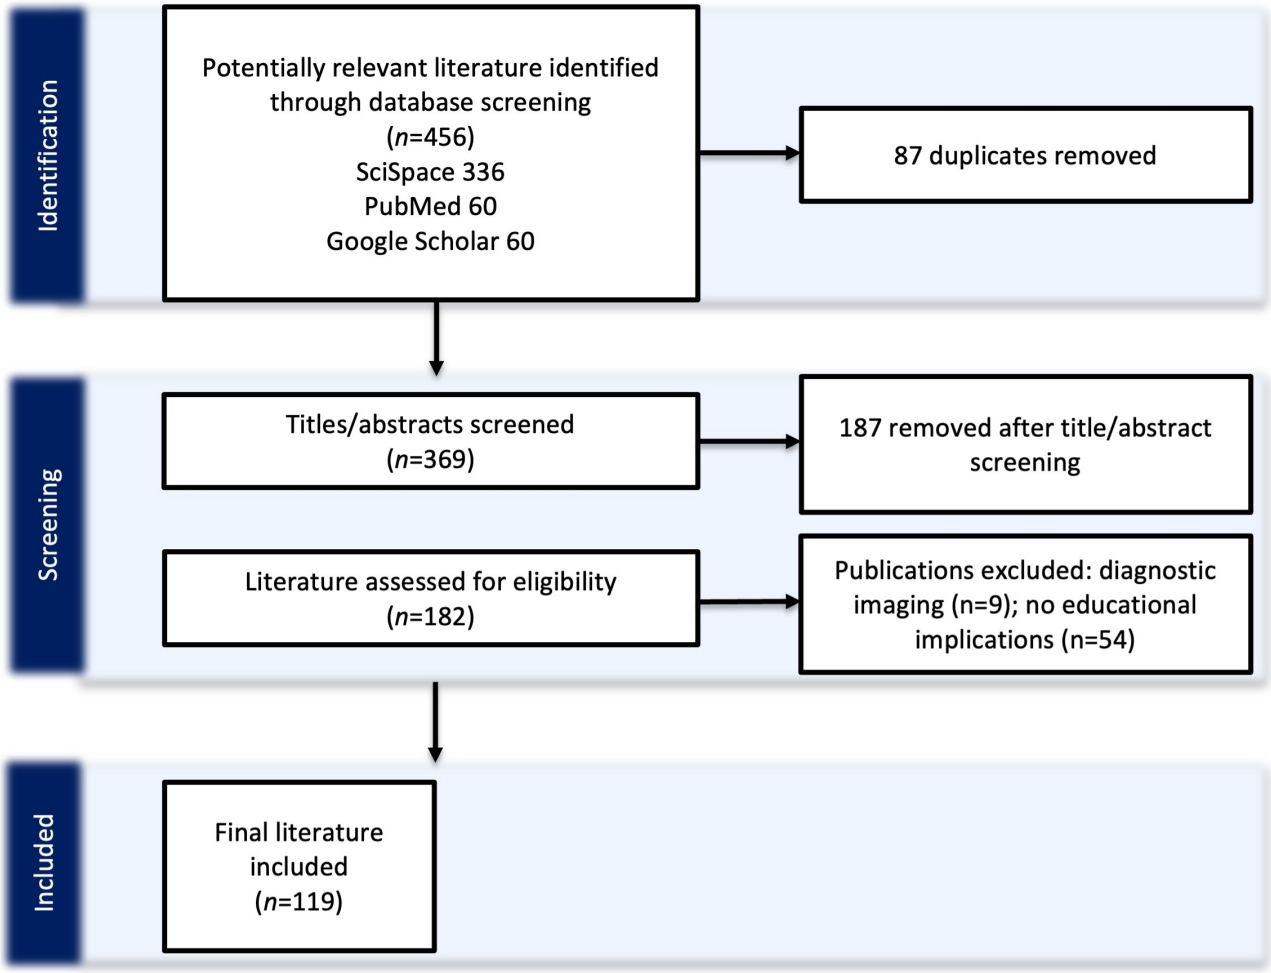
Rather than synthesizing findings study-by-study, the interpretive analysis examined relationships across the corpus to identify dominant narratives, underlying assumptions, conceptual tensions, and important omissions. Constant comparison was used throughout the analysis, with emerging interpretations repeatedly tested against the complete dataset to ensure that they adequately represented the breadth of the included literature.

Professional identity formation served as the interpretive framework through which dominant conceptualizations were examined, enabling the identification of both explicit discussions and notable silences relating to identity development, moral agency, clinical judgment, and preparation for algorithmically mediated practice.

The integration of corpus-level descriptive mapping with interpretive synthesis enabled the review to move beyond describing what has been published toward understanding how the field currently conceptualizes the educational implications of GenAI.

To enhance analytical rigor, all included publications were independently coded by 2 reviewers using the predefined coding framework. Coding decisions were subsequently compared, with any discrepancies discussed and resolved through consensus. Throughout the analytical process, category definitions and interpretations were iteratively refined to ensure consistency across the corpus while remaining grounded in the included literature. Given the interpretive nature of this integrative review, formal intercoder reliability statistics were not calculated. Instead, analytical trustworthiness was enhanced through independent coding, iterative discussion, and consensus-based refinement of the coding framework, consistent with established integrative review methodology.

Results



Study Characteristics

Overview of the Included Literature

The study selection process is presented in Figure 1. Database searches identified 456 records, of which 87 duplicates were removed. Following title and abstract screening, 250 records were excluded, leaving 119 publications that met the eligibility criteria and were included in the review.

XSL•FO
RenderX

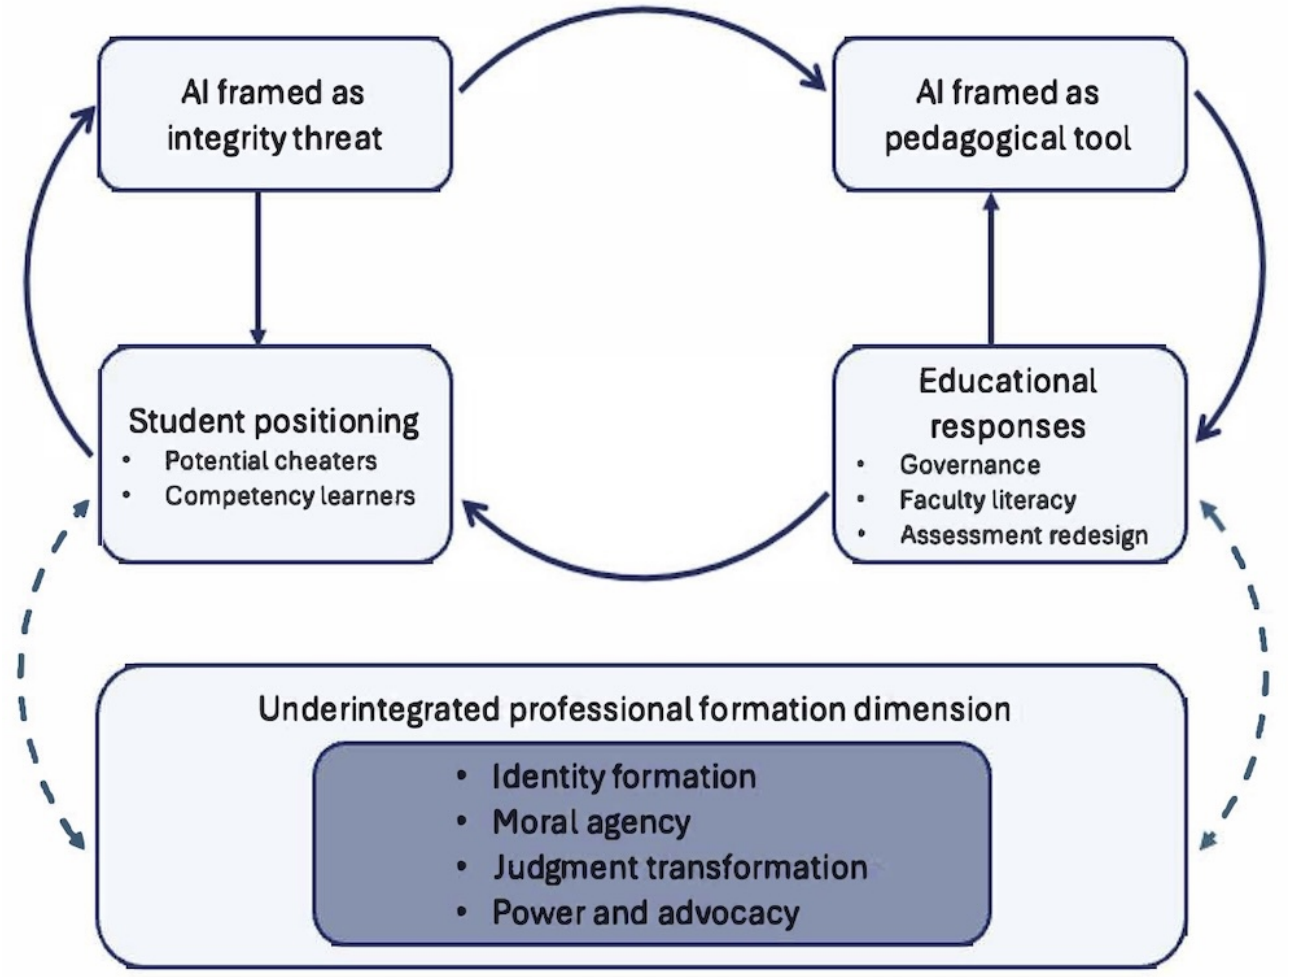
Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Of the 119 publications, 64 (53.8%) were empirical studies, 31 (26.1%) were scoping or systematic reviews, 13 (10.9%) were position papers or commentaries, and 11 (9.2%) were theoretical or framework papers. Publications originated from multiple geographical regions, with the strongest representation from the United States, China, Australia, and Europe. Publication volume increased rapidly over the review period, rising from 8 publications during 2022 - 2023 to 43 in 2024 and 68 in 2025 - 2026, reflecting the rapid expansion of scholarly interest following the public release of GenAI technologies (Table 1).

Table . Characteristics of included studies (n=119).

Characteristic	Values, n (%)
Empirical studies	64 (53.8)
Scoping/systematic reviews	31 (26.1)
Position papers/commentaries	13 (10.9)
Theoretical/framework papers	11 (9.2)
Publications by year	
2022 - 2023	8 (6.7)
2024	43 (36.1)
2025 - 2026	68 (57.1)

Rather than presenting isolated themes, the findings are organized around the dominant ways in which GenAI is conceptualized within the nursing education literature. Corpus-level mapping identified recurring conceptual framings across the included publications, while interpretive synthesis examined how these framings positioned students, educators, and professional preparation for algorithmically mediated practice. Figure 2 presents the resulting conceptual model that informed the thematic synthesis.



The included literature comprised empirical studies (n=64), scoping and systematic reviews (n=31), position papers and commentaries (n=13), and theoretical or framework papers (n=11). Geographic representation was global, with significant

XSL•FO
RenderX

contributions from the United States, China, Australia, and Europe. Publication frequency increased sharply over time, with 8 papers in 2022 - 2023, 43 in 2024, and 68 in 2025 - 2026, reflecting rapid scholarly response following the public release of GenAI technologies.

Figure 2 presents a conceptual model derived from the integration of corpus-level mapping and interpretive synthesis. The model illustrates a governance-pedagogy cycle anchored in integrity discourse, wherein AI is framed primarily as an integrity threat or a pedagogical instrument, generating governance and literacy-based responses. Professional formation in algorithmically mediated practice remains comparatively underintegrated within this cycle. The themes that follow elaborate on each component of this discourse cycle.

Figure 2. Conceptual model of generative AI discourse in nursing education. Synthesis revealed a dominant tool-oriented discourse cycle and comparatively limited integration of professional formation in algorithmically mediated practice.

Theme 1: AI as a Writing Tool and an Integrity Threat

The dominant discourse positioned GenAI primarily as a content-generation tool with implications for academic integrity, assessment validity, and authorship authenticity. Across the corpus, AI was most frequently discussed in relation to plagiarism, inappropriate assistance with assessments, and concerns regarding the integrity of student work, rather than its influence on professional preparation or future clinical practice.

Shorey et al [3] described ChatGPT as raising concerns regarding plagiarism, academic dishonesty, and the authenticity of student work, while Siah et al [4] similarly framed authenticity and academic integrity as the central educational challenges requiring investigation. Across the literature, 3 recurring subthemes characterized this integrity-focused discourse.

The first concerned assessment validity. Many publications questioned whether AI-generated work undermined assessment as a measure of student learning and clinical competence, often equating undisclosed AI use with plagiarism or other forms of academic misconduct [3-5]. The second focused on detection and governance, with considerable attention devoted to AI detection software, institutional policies, disclosure requirements, and faculty responsibilities for regulating AI use [5,16]. Finally, numerous publications advocated assessment redesign, recommending oral examinations, in-person assessments, authentic assessment tasks, and reflective activities that were perceived to be less vulnerable to AI-assisted completion [3,4,17].

Collectively, these studies positioned academic integrity as the principal educational problem associated with GenAI. Although this framing acknowledged legitimate concerns regarding

XSL•FO
RenderX

assessment authenticity, professional formation received comparatively limited attention within this dominant discourse.

Theme 2: AI as a Pedagogical Tool

Alongside the dominant integrity discourse, a smaller but growing body of literature conceptualized GenAI as a pedagogical resource capable of enhancing learning rather than threatening assessment integrity. These publications shifted attention from regulation and surveillance toward constructive educational integration.

Several pedagogical applications recurred throughout the corpus. AI was described as supporting clinical reasoning through the generation of patient scenarios, care plans, and differential diagnoses that students were required to critically evaluate [18-20]. Other studies emphasized personalized learning, describing AI systems that provided tailored feedback, adaptive learning opportunities, and conversational support for evidence-based practice [21,22]. Additional publications highlighted opportunities to improve accessibility, particularly for students with language barriers or diverse learning needs, while others positioned AI literacy itself as an emerging professional capability required for contemporary nursing practice [1,21,22].

Despite representing a more constructive framing than the integrity-focused literature, this discourse remained predominantly educational in orientation. AI was generally conceptualized as a teaching and learning resource rather than as a feature of contemporary clinical environments requiring explicit preparation for professional practice.

Theme 3: The Missing Discourse on Professional Formation in Algorithmic Practice

While integrity and pedagogy dominated the literature, a different pattern also emerged. Across the corpus, comparatively little attention was directed toward how AI might reshape the formation of nurses as professionals practicing within algorithmically mediated health care systems. Seven dimensions of professional formation were examined during the analysis, including identity formation, ethical reasoning, moral agency, clinical judgment, digital professionalism, awareness of algorithmic power, and recognition of AI within contemporary clinical practice.

Identity Formation, Moral Agency, and Clinical Judgment

Professional identity formation was explicitly addressed in only 12 of the 119 (10%) included publications. When identity was discussed, students were typically positioned as learners developing AI-related competencies rather than professionals negotiating evolving clinical roles and responsibilities. References to professional identity were commonly embedded within discussions of digital professionalism, focusing on appropriate AI use and disclosure practices rather than the broader developmental process through which nurses learn to think, act, and feel as members of the profession.

Moral agency was even less visible. Only 6 (5%) publications explicitly discussed nurses' responsibility to question, challenge, or override algorithmic recommendations when patient welfare required it. Although professional accountability was occasionally acknowledged, few studies described educational strategies for cultivating the moral courage needed to exercise independent clinical judgment within AI-supported practice environments.

Clinical judgment appeared more frequently, with 38 (31.9%) publications referring to critical thinking or decision-making. However, these discussions largely focused on evaluating AI-generated outputs rather than examining how algorithmic systems may reshape clinical reasoning itself. AI was commonly positioned as a learning scaffold supporting judgment, rather than as a technology transforming the contexts in which professional judgment is exercised.

Ethical Awareness, Power, and the Algorithmic Present

AI Ethics and Clinical Preparedness

Ethical issues were identified in approximately 38% of the corpus and were most commonly related to algorithmic bias, privacy, transparency, and the reliability of AI-generated information [9,11,23,24]. These discussions generally emphasized vigilance, verification, and technical oversight, with relatively few publications describing structured educational approaches to developing ethical reasoning in AI-supported clinical practice.

Similarly, approximately one-third of publications acknowledged algorithmic bias, inequity, or opacity, yet few translated these concerns into curricular approaches that prepared students to recognize, challenge, or respond to inequitable algorithmic decision-making. Student concerns regarding AI bias were evident in empirical studies, although participants frequently reported limited preparation for managing these issues in practice.

A further finding was the limited recognition that AI is already embedded within many contemporary health care systems. Across much of the literature, AI was discussed as an emerging or future technology despite its established role in early warning systems, clinical decision support, risk stratification, and documentation technologies. Taken together, these findings suggest that while ethical and technological issues receive growing attention, professional formation within algorithmically mediated health care remains comparatively underdeveloped.

Theme 4: Student Identity Construction From Threat to Opportunity

The analysis identified 4 dominant ways nursing students were positioned within the literature. First, students were frequently portrayed as potential academic integrity risks, requiring surveillance and regulation to prevent inappropriate AI use. Second, students were described as digitally capable but requiring guidance, reinforcing the faculty's responsibility for establishing appropriate boundaries and institutional expectations. Third, students were positioned as future professionals developing AI-related competencies, although competency development was generally framed in technical rather than professional terms. Finally, empirical studies portrayed students as pragmatic users seeking to integrate AI

XSL•FO
RenderX

into their learning while navigating uncertainty regarding institutional expectations.

Across these constructions, relatively little attention was directed toward students as professionals-in-formation preparing to practice alongside algorithmic technologies. Consequently, the literature rarely articulated how future nurses might develop professional judgment, moral agency, and relational practice within AI-enabled health care environments.

Theme 5: Proposed Educational Responses Involving Governance, Literacy, and Pedagogy

Three broad categories of educational response emerged across the literature: governance and policy development, faculty AI literacy, and pedagogical innovation. These responses largely reflected the dominant conceptual framings identified throughout the corpus.

Governance-focused publications advocated institutional policies, disclosure requirements, academic integrity training, and faculty guidance to regulate AI use within assessment [5,16,25]. Faculty development initiatives primarily focused on improving educators' technological knowledge, assessment design, and confidence in integrating AI into teaching [1,10,26]. Pedagogical innovations included AI-generated patient scenarios, structured evaluation of AI outputs, personalized feedback systems, and collaborative learning approaches in which students interacted directly with AI technologies [18-22,27,28].

Although these responses demonstrated increasing educational sophistication, they generally remained situated within existing curricular structures. Few publications proposed sustained curriculum transformation centered on professional identity formation, clinical judgment, or moral agency within algorithmically mediated practice environments.

Discussion

Principal Findings

The central finding of this review is a significant misalignment between how GenAI is framed within the nursing education literature and the realities of contemporary clinical practice. Among the 119 publications, the discourse is dominated by concerns about academic integrity (n=100, 84%), whereas comparatively little attention is given to professional identity formation (n=12, 10%) or moral agency (n=6, 5%). This imbalance suggests that nursing education is responding to GenAI primarily as an assessment problem rather than as a transformation of professional practice environments. Interpreting these findings through the lens of professional identity formation highlights how current discourse emphasizes governance and competency while underengaging with the developmental processes through which nurses learn to exercise judgment, agency, and relational care in technologically mediated practice environments.

Across the corpus, GenAI is most frequently conceptualized as a writing tool that threatens authorship authenticity and assessment validity [3-5]. This framing has generated extensive discussion about detection tools, policy frameworks, and assessment redesign [3,4,16]. While these concerns are legitimate, the prominence of this discourse risks positioning students primarily as potential rule-breakers rather than as emerging professionals who must develop judgment and ethical agency within algorithmically mediated health care systems.

Together, these findings identify an algorithmic formation gap in nursing education discourse. While the literature actively debates whether students should use AI in academic work, comparatively little attention is directed toward how nurses learn to practice alongside algorithmic systems in contemporary health care.

The Integrity Discourse: Necessary but Insufficient

The prominence of academic integrity discourse is not surprising. Academic integrity represents a familiar institutional challenge for universities, with established responses including plagiarism detection, honor codes, and assessment redesign [3,4]. Within this framing, GenAI becomes a new technological manifestation of a longstanding concern about academic misconduct.

However, this regulatory orientation may also reflect what can be understood as problem displacement. Integrity is a manageable challenge that universities can address through policy development, surveillance technologies, and compliance mechanisms [5]. By contrast, the deeper challenge posed by AI involves reconsidering how professional education prepares students for clinical practice environments increasingly shaped by algorithmic decision-support systems.

Empirical research suggests that students themselves often approach GenAI pragmatically. Rather than using AI primarily to circumvent learning, many students report using it as a study aid while expressing uncertainty regarding institutional expectations and professional boundaries [29-31]. An educational response focused primarily on prevention and detection may therefore overlook an important opportunity: developing the professional judgment required to navigate AI responsibly within clinical practice.

Integrity remains an essential foundation of professional practice. However, integrity discourse alone cannot adequately address the broader transformation of health care environments in which nurses must interpret, question, and sometimes override algorithmic recommendations.

The Algorithmic Formation Gap

If professional education aims to develop individuals who "think, act, and feel" like members of the profession [12], then the integration of AI raises fundamental questions for professional formation in nursing.

Professional identity formation involves the integration of professional values, knowledge, and behaviors into an individual's sense of self [12,13]. When clinical practice environments incorporate algorithmic decision-support systems, automated risk stratification tools, and AI-assisted documentation technologies, the context in which nurses develop professional identities is fundamentally altered.

XSL•FO
RenderX

This review suggests that nursing education discourse has not yet fully engaged with this transformation. While the literature acknowledges ethical and technological challenges associated with AI, sustained attention to how nurses develop professional identities within algorithmically mediated care environments remains limited.

It is important to acknowledge that nursing is not alone in responding to the educational implications of AI. Medical education has similarly focused on AI literacy, ethical considerations, governance, and the integration of AI into clinical reasoning curricula. More recently, however, medical education scholarship has begun to extend beyond technical competency by considering human-AI collaboration, professional responsibility, and professional identity formation as integral components of AI-enabled practice [6]. Likewise, broader work examining clinical decision-support systems has highlighted how algorithmic technologies may reshape clinicians' autonomy, judgment, and professional identity [7]. These developments suggest that professional formation is becoming an increasingly recognized concern across the health professions. However, the present review indicates that this perspective remains comparatively underdeveloped within the nursing education literature, where discourse continues to be dominated by academic integrity, assessment validity, and technological competency. Rather than positioning nursing as uniquely deficient, the findings suggest that nursing is participating in a broader transition across health professions education while highlighting opportunities for the discipline to more explicitly integrate professional identity formation into AI-related curriculum development.

The implications of this formation gap can be understood across 3 interrelated dimensions: thinking, acting, and feeling as a professional nurse.

Thinking: Clinical Judgment in Algorithmic Contexts

Clinical judgment is a foundational capability of professional nursing practice. Tanner's model of clinical judgment emphasizes the integration of noticing, interpreting, responding, and reflecting in complex patient situations [32].

The literature reviewed here frequently emphasizes the importance of critical evaluation of AI-generated outputs [18,19]. These approaches are valuable in developing analytical reasoning skills. However, they primarily frame clinical judgment as a capacity applied to algorithmic recommendations rather than as a capability that may itself be reshaped by algorithmic practice environments.

Algorithmic decision-support systems can introduce risks such as automation bias, in which clinicians defer to automated recommendations even when conflicting evidence is present [33]. Similarly, excessive reliance on automated outputs may contribute to deskilling, whereby clinicians' independent pattern recognition and intuition gradually diminish [34].

Preparing students for algorithmically mediated care therefore requires more than the ability to critique AI outputs. It requires developing the capacity to integrate algorithmic information into clinical reasoning while maintaining independent professional judgment.

Acting: Moral Agency and Professional Courage

A second dimension of professional formation concerns moral agency as the ability to act on ethical conclusions even when doing so requires challenging institutional or technological authority.

Nursing has long emphasized patient advocacy as a central professional responsibility [35]. In algorithmic contexts, advocacy may involve questioning automated recommendations, identifying bias within predictive models, or prioritizing individualized patient needs over standardized algorithmic outputs.

Despite the ethical concerns identified across the literature, including bias, transparency, and privacy, few papers address how nurses develop the moral courage required to challenge algorithmic decision-support systems when patient welfare demands it [9,11,23,36]. Ethical awareness alone is insufficient if it does not translate into the capacity for moral action.

Professional formation in the age of AI must therefore include opportunities for students to practice exercising judgment and advocacy in situations where algorithmic recommendations conflict with clinical assessment.

Feeling: Relational Care in Technologically Mediated Environments

A third dimension of professional identity formation concerns the relational and affective aspects of nursing practice. Nursing has historically defined itself through commitments to compassion, presence, and holistic patient care.

The integration of algorithmic technologies introduces new forms of technological mediation between nurses and patients. Clinical dashboards, automated alerts, and AI-assisted documentation systems may shift the focus of clinical attention from the bedside to the digital interface.

This shift raises important questions regarding how nurses sustain relational care and moral responsibility when clinical decision-making becomes increasingly mediated by technological systems. Professional formation must therefore address how nurses maintain human connection, empathy, and patient advocacy within technologically complex health care environments.

Addressing the Algorithmic Present

A striking observation from this review is the limited acknowledgment that AI is already embedded within contemporary health care delivery. Across the literature, AI is frequently framed as an emerging or future technology rather than as an existing component of clinical infrastructure.

In reality, algorithmic systems already influence many aspects of clinical practice, including sepsis prediction models, early warning systems, risk stratification tools, and automated documentation support within electronic health records. These systems shape triage decisions, clinical workflows, and resource allocation across health care settings.

The relative absence of this "algorithmic present" within nursing education discourse may reflect disciplinary boundaries or

XSL•FO
RenderX

technological invisibility, where background computational systems are not recognized as AI by educators and clinicians. However, preparing students for a technological future while underengaging with the algorithmic realities of contemporary practice risks widening the formation gap identified in this review.

Addressing this gap requires stronger partnerships between clinical environments and nursing education to ensure that curricula reflect the technological infrastructures already shaping health care delivery.

Toward a Professional Formation Framework

Addressing the algorithmic formation gap requires reframing AI integration as a professional formation challenge rather than a technological or regulatory issue.

This reframing shifts the focus from detecting inappropriate AI use toward preparing nurses to practice ethically and effectively within algorithmically mediated health care systems.

Table 2 outlines 5 conceptual shifts that may support this reframing. These shifts involve moving from integrity-focused discourse to curricular approaches that emphasize identity formation, moral agency, and professional judgment in technological contexts.

Examples of such approaches may include simulation scenarios involving algorithmic failures, structured reflection on professional identity in technologically mediated practice, and case-based ethical discussions involving AI-supported clinical decision-making.

Rather than treating AI as a discrete technological topic, nursing education may need to integrate AI considerations longitudinally across curricula, linking technological engagement with professional values, clinical reasoning, and patient advocacy.

Table . Proposed conceptual shifts for AI in nursing education.

Integrity/tool discourse	Professional formation framework
AI as an integrity threat	AI as a professional practice context
Tool competency and literacy	Identity formation (think/act/feel)
Ethical awareness/principles	Moral agency and professional resistance
Critical evaluation of output	Transformation of clinical judgment
Future technological preparation	Engagement with current algorithmic reality

Implications for Nurse Educators

For nurse educators, the findings of this review suggest that GenAI should not be addressed solely through academic integrity policies or isolated technological skills training. Instead, AI must be integrated into curricula as part of professional formation. This includes creating learning experiences in which students critically engage with algorithmic decision-support systems, reflect on their evolving professional identities in technologically mediated environments, and practice exercising clinical judgment when AI recommendations conflict with patient needs. By situating AI within professional formation rather than academic compliance, educators can better prepare graduates for contemporary health care systems in which algorithmic tools increasingly shape clinical practice.

Implications for Nursing Education

The question facing nursing education is no longer whether students should use AI in their coursework. The more pressing question is how nurses will exercise judgment, advocacy, and relational care within health care systems increasingly shaped by algorithmic decision-making.

Preparing students for these environments requires moving beyond governance and literacy toward professional formation. This includes creating opportunities for students to engage critically with AI systems, reflect on their evolving professional identities, and practice exercising clinical judgment in technologically complex care environments.

By reframing AI integration as a professional formation challenge, nursing education can ensure that graduates possess not only the technical literacy to interact with algorithmic systems but also the ethical judgment, moral courage, and relational capacity required to advocate for patients within them.

Limitations

This review has several limitations. First, the rapid evolution of GenAI means that relevant literature published or in press after the search period may not have been captured. Given the pace of scholarly and technological developments in this field, findings should be interpreted as a time-sensitive snapshot of the discourse between 2022 and early 2026. Second, the search was limited to English-language publications and 3 databases (PubMed, Google Scholar, and SciSpace). Although these sources captured a broad and diverse corpus, relevant studies indexed elsewhere or published in other languages may have been missed. Third, the integrative review design intentionally included heterogeneous evidence types, such as empirical studies, reviews, theoretical papers, and commentaries. While this breadth enabled conceptual mapping of the field, the inclusion of nonempirical literature may limit direct comparability across studies and may amplify emerging opinion-based discourse. Fourth, the analysis relied on explicit reporting within published papers. The absence of discussion regarding professional identity formation, moral agency, or recognition of clinical AI infrastructure in the literature does not necessarily indicate the absence of these considerations in educational practice; rather, it reflects their limited articulation within the published discourse. Finally, the interpretive synthesis

XSL•FO
RenderX

involved researcher judgment in coding and thematic interpretation. To enhance rigor, independent coding and reviewer discussion were used to refine categories and resolve disagreements.

Conclusions

This integrative review identifies a fundamental algorithmic formation gap in nursing education discourse. The literature predominantly frames AI as a content-generation tool and academic integrity threat, with extensive attention to detection, prevention, and policy frameworks. While these concerns are legitimate, the disproportionate focus on integrity may obscure a more critical challenge: preparing nursing students for professional practice in algorithmically mediated health care environments.

The literature's limited engagement with professional identity formation, moral agency, clinical judgment transformation, and the reality of algorithmic clinical practice represents a critical gap. Nursing education cannot adequately prepare students for contemporary practice if it treats AI primarily as a writing tool to be regulated rather than as a defining context for professional formation.

The absence of professional formation discourse is not merely a gap to be filled with additional content or competencies. It represents an argument for fundamental curricular transformation. If AI already mediates triage, diagnostics, care pathways, and clinical decision-making in practice settings and the evidence from health care delivery suggests it does, then nursing education must explicitly address how students develop professional identity, clinical judgment, and moral agency within these algorithmic contexts.

This transformation requires moving beyond the question "how do we prevent students from cheating with AI?" to the more fundamental question "how do we prepare students to think, act, and feel like nurses in algorithmically mediated care environments?" It requires recognizing that professional formation in the age of AI is not about acquiring discrete competencies but about developing the capacity to exercise clinical judgment, moral agency, and relational practice alongside algorithmic systems.

The nursing profession has long defined itself through commitments to patient advocacy, holistic care, clinical judgment, and moral courage. As algorithms increasingly mediate health care delivery, these professional commitments are not obsolete; they are more essential than ever. However, they require explicit, sustained, and curricular attention to how they are enacted in algorithmic contexts.

Nursing education stands at a critical juncture. Continuing to treat AI primarily as an integrity threat leaves graduates unprepared for the algorithmic reality of modern health care. By reframing AI integration as a professional formation challenge, nursing education can ensure that the next generation of nurses possesses not only the literacy to use AI but also the judgment and agency to advocate for patients within it.

Generative AI Use

During the preparation of this manuscript, the authors used ChatGPT (OpenAI) to assist with language editing, clarity, and structural refinement. All AI-assisted suggestions were critically reviewed by the authors, who retain full responsibility for the accuracy, originality, and integrity of the published work.

Abstract

Background: Discharge-planning nurses and case managers need to prioritize transitional care, but predictive ranking alone does not identify which patients will benefit from a specific intervention.

Objective: This study aimed to develop and temporally validate a local discharge time model for 30-day readmission; evaluate calibration, risk tiers, clinical utility, and subgroup performance; and describe historical nursing action cohorts only as non–model-triggered feasibility evidence for a future pathway.

Methods: This single-center observational study used 41,935 discharge episodes from 2017 to 2018. After excluding 2.3% (964/41,935) in-hospital deaths, 48.5% (19,890/40,971) of episodes from 2017 were used for development, and 51.5% (21,081/40,971) of episodes from 2018 were used for temporal validation. The outcome was the same-institution all-cause readmission within 30 days, defined as the union of readmissions on days 1 to 14 and 15 to 30. Logistic regression, random forest, and Extreme Gradient Boosting were calibrated using 5-fold out-of-fold predictions from 2017. The 95% CIs were obtained with 1000 stratified bootstrap replicates. The separate historical cohorts included shared decision-making (n=72), long-term care linkage (n=364), and remote monitoring (n=43). None was selected or routed by model output.

Results: The validation cohort had 20.7% (4361/21,081) readmissions. Random forest was selected from development cross-validation and achieved an area under the receiver operating characteristic curve (AUROC) of 0.816 (95% CI 0.809-0.823), area under the precision-recall curve (AUPRC) of 0.593 (95% CI 0.579-0.607), and Brier score of 0.119 (95% CI 0.116-0.121); the calibration intercept was –0.117, the slope was 0.974, and the observed-to-expected ratio was 0.951. Readmission occurred in 6.5% (661/10,120) of low-risk episodes, 18.5% (1160/6271) of moderate-risk episodes, 47.3% (1769/3739) of high-risk episodes, and 81.1% (771/951) of very high–risk episodes. The principal diagnosis group accounted for 84.6% of the random forest importance. After excluding index episodes labeled as planned admission or discharge and refitting, the AUROC decreased to 0.726, and the AUPRC decreased to 0.284. In historical cohorts, discharge direction changed in 41.7% (30/72) of cases; 82.7% (301/364) of patients used long-term care; 90.2% (268/297) of patients with valid dates started service within 7 days; and the uncontrolled remote monitoring cohort showed exploratory 3-month reductions in hospital days, emergency visits, and readmissions.

Conclusions: The recalculated local model showed useful temporal discrimination and near-unity calibration after probability calibration, but its performance depended heavily on diagnosis coding and potentially planned readmissions. External generalizability and model actionability remain unestablished. Prospective silent-run evaluation, local threshold review, subgroup monitoring, and controlled testing of the nurse-led response are required before clinical activation.

Introduction

Thirty-day readmission remains an important indicator of discharge quality and postacute care transitions, and reducing avoidable readmission is a continuing health system priority [1,2]. Discharge-planning nurses and case managers coordinate patient and caregiver education, medication reconciliation, postacute referrals, and postdischarge escalation. Recent international syntheses indicate that transitional care can reduce health care use, but effectiveness varies by population, intervention complexity, follow-up duration, and implementation fidelity [3,4]. Hospitals, therefore, need transparent ways to prioritize limited nursing resources rather than delivering the most intensive intervention to every patient.

Readmission models frequently achieve only modest discrimination and may not translate into useful bedside decisions [5,6]. Earlier transitional care reviews similarly showed heterogeneous intervention effects [7,8]. Recent work suggests that nursing data can contribute predictive information beyond administrative variables [9]. Predictive performance, however, is distinct from clinical actionability: a model may rank patients by risk without identifying who will respond to shared decision-making, long-term care linkage, remote monitoring, or another care component.

Our institutional program previously examined discharge-planning effectiveness, nursing care models, remote health monitoring, and shared decision-making with long-term care linkage [10-13]. These studies describe potentially feasible care components, but they do not constitute a model-triggered intervention pathway. The present study, therefore, treats those cohorts only as historical, illustrative evidence of feasibility and not as proof that the prediction model improves outcomes.

Prediction model guidance emphasizes transparent data sources, predictor timing, outcome definitions, validation, calibration, and applicability [14-16]. For nursing informatics, a further concern is that functional status, caregiver capacity, health literacy, self-management ability, symptom burden, and nursing complexity may be documented in structured assessments, standardized nursing terminologies, or narrative notes rather than administrative fields. Natural language processing and standardized nursing concepts offer possible methods for recovering this information [17-20].

This study aimed to (1) develop and temporally validate a single-center discharge time model for same-institution 30-day readmission; (2) evaluate probability calibration, risk tier separation, decision curve net benefit, subgroup performance, and sensitivity to outcome and cohort definitions; and (3) describe historical nursing action cohorts as illustrative evidence for designing a future, prospectively evaluated workflow. We did not test whether model-triggered transitional care improved patient outcomes.

Methods

Study Design and Setting

We conducted a multicomponent observational study at National Taiwan University Hospital Yunlin Branch. The primary component was the development of a prediction model using discharge episodes from 2017, with temporal validation on 2018 episodes. Historical shared decision-making, long-term care linkage, and remote monitoring datasets were analyzed separately to describe the available nursing services. The model was not visible to clinicians, did not alter care, and did not trigger enrollment in any historical cohort. The action cohorts were not used for model training, calibration, model selection, threshold derivation, or treatment effect estimation.

Prediction Cohort and Outcome

The source extract contained 41,935 discharge episodes. We excluded 964 episodes ending in in-hospital death, leaving 40,971 episodes for analysis: 19,890 in 2017 and 21,081 in 2018. All age groups were retained. The deidentified extract did not contain a stable patient identifier. Therefore, unique patient counts could not be reconstructed, and repeated discharge episodes were treated as independent observations (Table S1 in Multimedia Appendix 1).

The primary outcome was same-institution all-cause readmission within 30 days after discharge. The raw dataset contained separate indicators for readmission on days 1 to 14 and days 15 to 30; the cumulative 30-day outcome was defined as either indicator being positive. The extract did not capture readmissions to other hospitals and did not provide a reliable indicator distinguishing planned from unplanned subsequent admissions. Accordingly, potentially planned readmissions were included in the primary outcome.

During revision, an audit of the raw readmission fields identified that the previously reported 9.7% reflected only days 15 to 30 rather than cumulative 30-day readmission. The outcome was reconstructed as the logical union of the 2 windows, and all downstream analyses were rerun. The revised outcome definition, analysis code, and outputs were independently reviewed and verified by the authors and study statistician (Table S1 in Multimedia Appendix 1).

Postdischarge deaths were not treated as censoring events because the extract did not support time-to-event modeling with complete competing risk data. Among the analytic episodes, 233 deaths occurred within 30 days after discharge; 105 had a recorded readmission before death, and 128 did not. Episodes without a recorded readmission were classified as nonevents. Sensitivity analyses excluded these deaths and used a composite of readmission or death within 30 days.

Candidate Predictors and Missing Data

Candidate predictors were restricted to information available at discharge: age band, sex, length of stay, broad principal diagnosis group, and discharge destination group. Age was categorized as 0 to 17 years, 18 to 39 years, 40 to 59 years, 60 to 79 years, or 80 years or older. Principal diagnosis labels that changed between calendar years were harmonized into clinically broad groups, including a planned admission or discharge category. Destination indicators and raw disposition codes were combined into the following categories: home, facility, acute transfer, community service, other, or missing. The putative prior readmission field was not modeled because it was blank

XSL•FO
RenderX

in 99.9% (40,931/40,971) of the episodes and could not be interpreted reliably.

Age was missing in 0.0% (1/40,971) of episodes, length of stay was missing in 2.2% (887/40,971), and discharge destination was missing in 6.3% (2566/40,971); sex and diagnosis group were complete after harmonization. Categorical missingness was represented explicitly. Length of stay was capped at the 99th percentile in 2017 (54 days), transformed as log(1 + length of stay), and median imputed within the modeling pipeline. Variable definitions are reported in Table S2 in Multimedia Appendix 1, and period-level missingness is reported in Table S1 in Multimedia Appendix 1.

Model Development, Calibration, and Temporal Validation

We evaluated prespecified logistic regression, random forest, and Extreme Gradient Boosting models. Categorical variables were one-hot encoded. Categories occurring fewer than 5 times were grouped by the encoder. Hyperparameters were fixed before examining the 2018 validation outcomes and are reported in Table S3 in Multimedia Appendix 1. Five-fold stratified cross-validation within 2017 generated out-of-fold predictions. Logistic calibration (Platt scaling) was fitted to these out-of-fold predictions and then applied to predictions from each model refitted on all 2017 episodes.

The candidate model with the highest 2017 out-of-fold area under the precision-recall curve (AUPRC) was selected; Brier score and area under the receiver operating characteristic curve (AUROC) were secondary criteria. The untouched 2018 cohort was used for temporal validation. Performance was summarized using the AUROC, AUPRC, Brier score, calibration intercept, calibration slope, mean predicted risk, observed-to-expected ratio, and a decile calibration plot [14-16] (Table S4 and Figure S1 in Multimedia Appendix 1). The 95% CIs for the AUROC, AUPRC, and Brier score were calculated using 1000 stratified nonparametric percentile bootstrap replicates with seed 20260801. The existing institutional rule-based high-risk flag was retained as a comparator and evaluated in the temporal validation cohort.

Decision curve analysis estimated the net benefit across risk thresholds from 0.05 to 0.50. Because this was a retrospective decision analytic assessment and the score triggered no care, net benefit was interpreted as providing potential decision support rather than as demonstrating clinical effectiveness (Figure S2 in Multimedia Appendix 1).

Operational Risk Tiers

Four provisional tiers were derived from the calibrated 2017 out-of-fold random forest distribution: below the 50th percentile, from the 50th to below the 80th percentile, from the 80th to below the 95th percentile, and the 95th percentile or higher. The resulting cutoff points (0.1256, 0.3014, and 0.7746) were applied without re-estimation to 2018. Intervals were lower inclusive and upper exclusive except for the low tier, which included probabilities below 0.1256, and the very high tier, which included probabilities of 0.7746 or higher. The tiers were designed for workload planning, not as validated treatment thresholds (Table S5 in Multimedia Appendix 1).

Subgroup and Sensitivity Analyses

For the selected random forest, we calculated the AUROC, AUPRC, Brier score, observed-to-expected ratio, and calibration slope within age (<65 vs ≥65 years), sex, diagnosis group, and discharge destination subgroups when sample size and event counts permitted. Sensitivity analyses excluded postdischarge deaths within 30 days, used a readmission-or-death composite, restricted the cohort to adults, and excluded index episodes labeled as planned admission or discharge. The fixed-model analysis applied the full cohort model unchanged to the restricted 2018 subset; the refitted analysis re-estimated the random forest and its calibration using the corresponding restricted 2017 subset. This index diagnosis exclusion is an imperfect proxy for potentially planned readmissions, not a direct classification of whether a subsequent admission was scheduled. Random forest feature importance was summarized descriptively, with full subgroup and sensitivity results reported separately (Tables S6-S9 in Multimedia Appendix 1).

Historical Nursing Action Cohorts and Data Provenance

Three historical datasets were used only to illustrate candidate components for a future nurse-led pathway. No patient was selected or routed to these services by the prediction model. The supplied 72-case shared decision-making dataset and 364-case long-term care dataset match the sample sizes and key outcomes reported by Huang et al [13]. They are therefore treated as overlapping study arms rather than independent evidence. Their incremental contribution here is limited to corrected descriptive denominators and explicit placement within a proposed, not-yet-implemented workflow, consistent with guidance on overlapping publication [21] (Table S10 in Multimedia Appendix 1).

The supplied remote monitoring workbook contained 43 patients enrolled between November 12, 2020, and November 10, 2021, with 3-, 6-, and 12-month use windows. It appears to be an updated or overlapping program dataset compared with the previously published cohort [11], but no patient-level crosswalk was available to quantify the overlap. It is therefore presented as historical program data and not as an independent replication.

Remote monitoring outcomes were paired count measures and were compared using 2-sided Wilcoxon signed-rank tests. No multiplicity adjustment was applied. All *P* values are exploratory. The uncontrolled pretest-posttest design is vulnerable to regression to the mean, secular trends, and confounding by indication and does not support causal claims (Table S11 in Multimedia Appendix 1).

Proposed Future Nursing Workflow

The proposed pathway separates retrospective model evaluation from future clinical use. Phase 1 is a prospective silent run in which predictions remain hidden and do not change care. The hospital information system would log data availability, missingness, scores, tiers, outcomes, drift, subgroup performance, and projected nursing workload. Only after prespecified technical, calibration, equity, and operational review should activation be considered. In any subsequent activation, the score should prompt structured nursing

XSL•FO
RenderX

assessment and shared decision-making rather than automatically determining discharge placement or service enrollment [22] (Table S12 in Multimedia Appendix 1).

Statistical Analysis of Historical Cohorts

Continuous variables were summarized as means with SDs or medians with IQRs, as appropriate; categorical variables were summarized as counts and percentages. Long-term care initiation times were calculated only when service use and valid nonnegative discharge-to-service dates were available. Remote monitoring means were retained for comparability with the program dataset, while Wilcoxon signed-rank tests were used for paired inference.

Ethical Considerations

This study was approved by the Research Ethics Committee of National Taiwan University Hospital Yunlin Branch (202403148RINE). Because routinely collected clinical data and retrospectively assembled cohorts were used, the requirement for informed consent was waived. Patients and the public were not involved in the design, conduct, reporting, or dissemination planning of this retrospective analysis. Future prospective deployment should include patient and caregiver feedback on risk communication, shared decision-making, and the acceptability of remote monitoring.

Results

Cohort Flow and Characteristics

Of 41,935 source discharge episodes, 964 in-hospital deaths were excluded, leaving 40,971 analytic episodes. Mean age was 62.2 (SD 17.9; range 0-105) years, 57.2% (23,425/40,971) of the episodes involved male patients, and median length of stay was 5 (IQR 3-9) days. The cumulative same-institution 30-day readmission rate was 20.8% (8536/40,971), comprising 4465 events on days 1 to 14 and 4071 events on days 15 to 30. The 2017 development cohort contained 21.0% (4175/19,890) of the events. The 2018 validation cohort contained 20.7% (4361/21,081) of the events (Table S1 in Multimedia Appendix 1).

Model Performance and Calibration

Random forest achieved the highest development out-of-fold AUPRC and was selected before temporal validation. In 2018, it achieved an AUROC of 0.816 (95% CI 0.809-0.823), an AUPRC of 0.593 (95% CI 0.579-0.607), and a Brier score of 0.119 (95% CI 0.116-0.121; Table 1). Extreme Gradient Boosting had a slightly higher AUROC but lower AUPRC, while logistic regression was less discriminative. The existing rule-based flag had an AUROC of 0.527; readmission occurred in 24.5% (1181/4817) of flagged episodes and 19.6% (3180/16,264) of unflagged episodes (Table 1).

Table . Temporal validation performance of candidate models[a].

Models[b]	AUROC[c] (95% CI)	AUPRC[d] (95% CI)	Brier score (95% CI)
Random forest	0.816 (0.809-0.823)	0.593 (0.579-0.607)	0.119 (0.116-0.121)
Extreme Gradient Boosting	0.817 (0.810-0.824)	0.589 (0.575-0.604)	0.119 (0.116-0.121)
Logistic regression	0.806 (0.798-0.813)	0.541 (0.528-0.557)	0.121 (0.119-0.124)

[a]95% CIs for the 3 statistical models were calculated using 1000 stratified nonparametric percentile bootstrap replicates. The binary rule-based flag was included as an operational comparator; a bootstrap CI was not calculated for that fixed flag.

[b]Existing rule-based flag: AUROC=0.527, AUPRC=0.217, and Brier score=0.323.

[c]AUROC: area under the receiver operating characteristic curve.

[d]AUPRC: area under the precision-recall curve.

The random forest calibration intercept was –0.117, the calibration slope was 0.974, and the observed-to-expected ratio was 0.951; the mean predicted risk was 21.8% (SD 22.2%) compared with an observed rate of 20.7% (4361/21,081). The calibration plot is provided in Figure S1 in Multimedia Appendix 1. Decision curve analysis showed greater net benefit than treat-all and treat-none strategies across thresholds from 0.05 to 0.50, but this retrospective analysis does not establish benefit from actual clinical use (Figure S2 in Multimedia Appendix 1).

Operational Risk Tiers

Applying development-derived probability cutoff points to the 2018 cohort produced a steep readmission gradient (Table 2). The validation distribution differed modestly from the target 50%, 30%, 15%, and 5% development proportions, as expected in temporal validation. These tiers describe risk separation and projected workload; they were not used to assign care (Table S5 in Multimedia Appendix 1).

XSL•FO
RenderX

Table . Random forest risk tiers in the 2018 temporal validation cohort[a].

Tier	Validation[b], n (%)	Readmission, n/N (%)	Calibrated score interval	Illustrative future nursing action
Low	10,120 (48.0)	661/10,120 (6.5)	<0.1256	Standard education and routine follow-up
Moderate	6271 (29.7)	1160/6271 (18.5)	0.1256 to <0.3014	Nurse follow-up and medication reconciliation
High	3739 (17.7)	1769/3739 (47.3)	0.3014 to <0.7746	Case management review; assess SDM[c], home care, or long-term care
Very high	951 (4.5)	771/951 (81.1)	≥0.7746	Multidisciplinary review; assess intensive follow-up or facility needs

[a]Cutoff points were the 50th, 80th, and 95th percentiles of calibrated 2017 out-of-fold random forest predictions. Intervals are lower inclusive and upper exclusive except the low tier and the very high lower bound shown above. Actions are illustrative and were not delivered according to model output.

[b]Validation-cohort percentages use all 21,081 discharge episodes as the denominator (N=21,081).

[c]SDM: shared decision-making.

Feature Importance, Subgroups, and Sensitivity Analyses

The principal diagnosis group accounted for 84.6% of the total random forest impurity importance, followed by length of stay (8.6%), age band (4.5%), sex (1.2%), and discharge destination (1.2%). The planned admission or discharge indicator alone accounted for 62.5% of the total importance. In validation, 74.0% (1783/2411) of the episodes in the planned category had a recorded 30-day return (Table S6 in Multimedia Appendix 1).

Subgroup performance was heterogeneous. Random forest AUROC was 0.861 among patients younger than 65 years and 0.751 among those aged 65 years or older. It was 0.827 in female episodes and 0.807 in male episodes. By discharge destination, AUROC was 0.825 for home discharge but 0.539 for facility discharge. Diagnosis-specific AUROC values were generally modest despite substantial overall discrimination, consistent with strong separation between diagnosis categories rather than uniformly strong within-category ranking. Full subgroup results are reported in Tables S7 and S8 in Multimedia Appendix 1.

Excluding index episodes labeled as planned admission or discharge and refitting the random forest reduced the validation sample to 18,670 episodes with 2578 (13.8%) readmissions. AUROC decreased to 0.726, AUPRC decreased to 0.284, and the calibration slope was 0.936. Results were materially unchanged when postdischarge deaths were excluded, when readmission or death was used as a composite, or when analysis was restricted to adults (Table S9 in Multimedia Appendix 1).

Historical Nursing Action Cohort Outcomes

Selected historical nursing cohort outcomes not triggered by the model are listed in Table 3. In the overlapping shared decision-making dataset, discharge direction changed in 41.7% (30/72) of cases, the recommended and actual directions were concordant in 59.7% (43/72) of cases, and 15.3% (11/72) of patients had any readmission within 30 days. In the overlapping long-term care dataset, 82.7% (301/364) of patients used long-term care services. Among 297 users with valid nonnegative service dates, the median time to service initiation was 1 (IQR 0-5) day, 66.7% (198/297) initiated within 3 days, and 90.2% (268/297) initiated within 7 days (Table S13 in Multimedia Appendix 1).

XSL•FO
RenderX

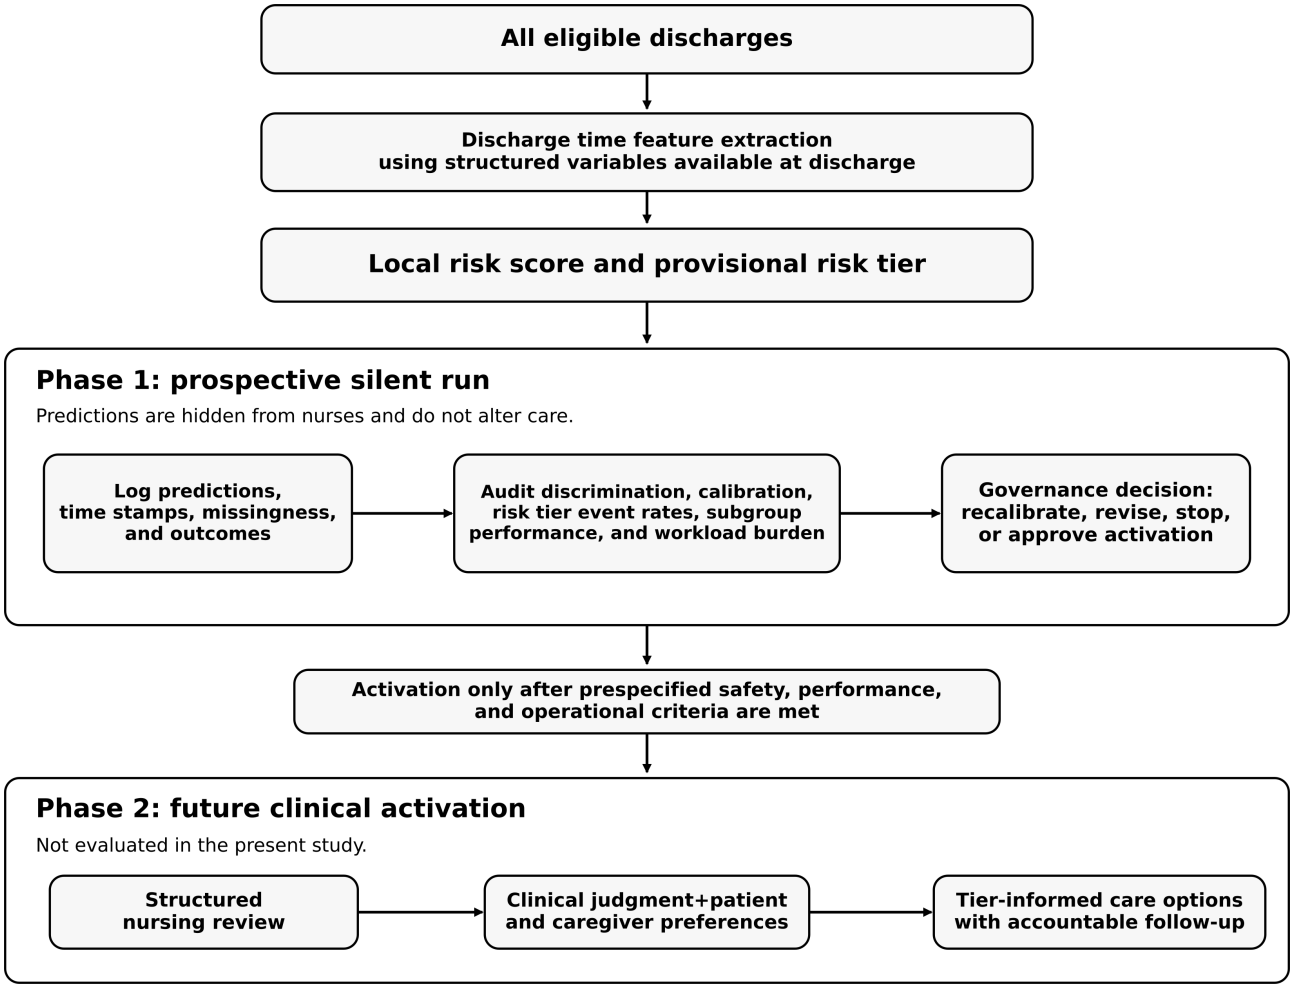
Table . Selected historical nursing cohort outcomes not triggered by the model[a].

Historical cohort and outcome	Result[b]	Interpretation
Shared decision-making dataset		
Discharge direction changed	30/72 (41.7%)	Previously reported arm; illustrative only
Any 30-d readmission	11/72 (15.3%)	Union of 1-14–d and 15-30–d indicators
Long-term care dataset		
Used long-term care services	301/364 (82.7%)	Previously reported comparison arm
Long-term care users with valid dates		
Service started within 7 d	268/297 (90.2%)	Median 1 (IQR 0-5) d
Remote monitoring		
3-mo hospital days[c]	Mean of 9.49 (SD 14.78) before enrollment to mean of 3.51 (SD 9.63) after enrollment (*P*=.02)	Exploratory Wilcoxon comparison
3-mo emergency visits[c]	Mean of 0.65 (SD 0.69) before enrollment to mean of 0.19 (SD 0.55) after enrollment (*P*=.001)	Exploratory Wilcoxon comparison
3-mo readmissions[c]	Mean of 0.58 (SD 0.59) before enrollment to mean of 0.28 (SD 0.63) after enrollment (*P*=.02)	Exploratory Wilcoxon comparison

[a]The 72- and 364-case datasets overlap with the study by Huang et al [13]. The 43-patient remote monitoring dataset appears updated or overlapping with the study by Po et al [11], but patient-level overlap could not be quantified. No historical cohort was selected or routed using model scores.

[b]Results are presented as n/N (%) for the shared decision-making and long-term care datasets and as means, SDs, and *P* values for the remote monitoring dataset.

[c]Mean changes from before to after enrollment (SD) were −5.98 (17.57) for 3-month hospital days, −0.47 (0.83) for 3-month emergency visits, and −0.30 (0.77) for 3-month readmissions.



In the 43-patient remote monitoring dataset, 3-month hospital days decreased from a mean of 9.49 (SD 14.78) before enrollment to 3.51 (SD 9.63) after enrollment (mean change –5.98; *P*=.02), emergency visits decreased from a mean of 0.65 (SD 0.69) to 0.19 (SD 0.55) (mean change –0.47; *P*=.001), and readmissions decreased from a mean of 0.58 (SD 0.59) to 0.28 (SD 0.63) (mean change –0.30; *P*=.02), while outpatient visits increased from a mean of 0.88 (SD 1.42) to 1.60 (SD 1.56) (mean change +0.72; *P*=.02). At 6 months, emergency visits and readmissions remained lower, whereas hospital days did not differ significantly. At 12 months, the differences in emergency visits and hospital days were not statistically significant. Because no multiplicity correction or concurrent control group was used, these findings represent only exploratory associations (Table 3 and Table S11 in Multimedia Appendix 1).

Proposed Implementation Pathway

Figure 1 shows the proposed 2-phase pathway. A prospective silent run, technical audit, calibration, subgroup review, and nursing workload assessment precede any activation. If activation is approved later, model output should initiate structured nursing review and shared decision-making rather than automatically determining the discharge destination or service enrollment (Table S12 in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 1. Proposed staged nursing-facing discharge risk workflow. Historical nursing action cohorts are illustrative and are not triggered by the model. Phase 1 is a prospective silent run and phase 2 represents future clinical activation only after prespecified safety, performance, equity, and operational criteria are met.

The historical shared decision-making, long-term care linkage, and remote monitoring cohorts in this study were illustrative.
They were not selected, routed, or treated according to model output and do not establish treatment benefit among model-defined risk groups.

Discussion

Principal Findings

This recalculated single-center study has 4 main findings. First, the corrected cumulative 30-day outcome occurred in approximately one-fifth of discharge episodes rather than the previously reported 9.7%, which represented only the window of days 15 to 30. Second, a calibrated random forest showed useful temporal discrimination, precision-recall performance, and near-unity calibration. Third, the overall performance and tier gradient were driven heavily by principal diagnosis, particularly index episodes labeled as planned admission or discharge. Discrimination decreased substantially when this category was excluded. Fourth, the historical nursing cohorts described available services but did not demonstrate that the model identified patients who benefited from those services.

A model can identify patients with a higher probability of readmission without identifying which intervention, if any, will reduce that probability. Demonstrating actionability requires the prospective linkage of model output to a predefined nursing assessment and care pathway, the measurement of treatment delivery and workload, and the comparison with an appropriate control strategy. The historical cohorts supply only feasibility information for designing that future evaluation.

Probability calibration was acceptable after Platt scaling, and decision curve analysis suggested potential net benefit across a broad range of thresholds. Nevertheless, the high readmission rate in the very high tier should not be interpreted as evidence that intensive transitional care will reduce events. The outcome included potentially planned returns, and the cutoff points were distribution based rather than derived from treatment effects or cost-effectiveness. Before activation, thresholds should be reviewed against contemporary event rates, nurse capacity, intervention eligibility, and the relative harms of missed and unnecessary escalation.

The dominance of the diagnosis group is both a performance signal and a vulnerability. It indicates that differences between broad diagnostic pathways explained much of the observed risk, but it also makes the model sensitive to coding changes, planned care patterns, and case mix shifts. The decrease in performance after excluding this index diagnosis category demonstrates sensitivity to index admission case mix; it does not establish

XSL•FO
RenderX

performance for confirmed unplanned subsequent readmissions. Lower performance among older patients and facility discharges also supports prospective subgroup monitoring and caution against a single unexamined threshold for all populations.

The current model omits many determinants of successful care transitions. Recent research on readmissions using nursing data suggests that nursing assessments may provide useful predictive information [9]. Narrative documentation may contain functional limitations, caregiver concerns, self-management barriers, symptom burden, education needs, and home care feasibility that are not visible in administrative coding. Natural language processing and terminology mapping can extract and standardize such activities, although methods and performance reporting remain heterogeneous [17,18].

Health literacy deserves particular attention. Prospective multicenter evidence indicates that inadequate health literacy is associated with readmissions and emergency department visits, especially among patients with high nursing complexity [19]. Standardized nursing diagnoses may also provide clinically interpretable predictors; a recent random forest study ranked individual nursing diagnoses by relevance to intensive care transfer [20]. Future refinement should evaluate structured nursing diagnoses, nursing complexity, health literacy, caregiver burden, functional dependency, discharge readiness, and medication self-efficacy.

No valid external validation was available, and generalizability beyond the development hospital has not been established. We removed the previously proposed University of California, Irvine (UCI) diabetes benchmark because its population, era, feature definitions, and outcome structure were too mismatched to support a clinically meaningful external validation claim. A future external study should use contemporaneous, clinically comparable data with harmonized outcome definitions, handling of planned readmissions, complete calibration assessment, and local recalibration as needed.

A future prospective study should begin with a silent run. Technical reliability, data latency, missingness, calibration, subgroup performance, case manager capacity, review time, alert burden, overrides, and care bundle completion should be measured before scores are shown to clinicians. Early-stage live evaluation should follow relevant clinical AI guidance, including DECIDE-AI (Developmental and Exploratory Clinical Investigations of Decision Support Systems Driven by Artificial Intelligence) [23]. Any subsequent randomized evaluation of an AI-triggered care bundle should follow the CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) [24] guidelines.

Limitations

This study has substantial limitations. It is a single-center retrospective development and temporal validation study without external validation. The outcome captured only same-institution returns and could not distinguish between planned and unplanned readmissions. Therefore, it is not equivalent to avoidable readmissions. Patient identifiers were unavailable, so repeated episodes were treated as independent, and patient-level clustering could not be modeled. Postdischarge deaths were retained as nonreadmissions when no prior return was recorded, although sensitivity analyses were stable. The feature set was parsimonious; diagnosis dominated; and excluded functional, social, caregiver, medication, physiological, and nursing assessment data. The risk tiers were based on score quantiles and have not been linked to treatment benefit or resource optimization. Subgroup results were retrospective, and some categories were small. The historical nursing datasets overlap with prior publications, are not linked to model scores, and do not constitute independent or causal evidence. The remote monitoring analysis was small, uncontrolled, and susceptible to regression to the mean and confounding by indication and involved multiple exploratory comparisons without multiplicity adjustment.

Conclusions

A calibrated discharge time random forest stratifies discharge episodes according to their predicted risk of readmission to the same hospital within 30 days after discharge, but the apparent performance depended heavily on diagnosis coding and potentially planned returns. Current evidence supports retrospective model evaluation and implementation planning but not external generalizability, automated care assignment, or benefit from model-triggered nursing interventions. A prospective silent run, explicit ascertainment of planned vs unplanned subsequent readmissions, subgroup and workload monitoring, local threshold review, and a later controlled evaluation of the nurse-led response are prerequisites for clinical activation.

Acknowledgments

The authors thank the discharge-planning, case management, shared decision-making, remote monitoring, and long-term care linkage teams of National Taiwan University Hospital Yunlin Branch for maintaining the clinical registries used in this study.

Generative AI Use

During revision, ChatGPT (GPT-6 Astra Pro; OpenAI) was used for language editing, document organization, and code-assisted verification and reanalysis of the deidentified datasets supplied by the authors. All variable definitions, code, outputs, interpretations, and manuscript changes were independently reviewed and verified by the authors and the study statistician. The AI tool did not make clinical decisions, determine authorship, or assume responsibility for the conclusions. The authors retain full responsibility for the accuracy and integrity of the work.

Funding

This research received no external funding.

Data Availability

The deidentified institutional datasets are not publicly available because they contain patient-level hospital information and are subject to institutional privacy and governance restrictions. Qualified investigators may request access to a governed analytical dataset from the corresponding author and host institution subject to institutional review and a data use agreement. Variable definitions, fixed hyperparameters, software versions, and random seed are documented in Tables S2 and S3 in Multimedia Appendix 1. A governed copy of the analysis code may be requested from the corresponding author subject to institutional review. Patient-level data are not embedded in the code.

Authors' Contributions

HWP and CYC conceived the study and drafted the manuscript. HWP, TYH, YCC, and HCT curated the data and interpreted the results. CHY performed the primary analyses and validation. CYC supervised the study. All authors critically revised the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: AI is rapidly transforming clinical nursing, promising administrative relief and decision support. However, the frontline reality presents a double-edged sword effect, where technological empowerment is frequently offset by novel occupational burdens and technostress.

Objective: This study aims to theoretically deconstruct the bidirectional impacts of AI application among clinical nurses and identify buffering conditions, using the Job Demands-Resources (JD-R) theoretical framework.

Methods: A descriptive qualitative study was conducted across multiple general hospitals in mainland China. Using maximum variation and purposive sampling, semistructured in-depth interviews were conducted with registered nurses who actively use clinical AI systems. Data were analyzed using directed qualitative content analysis guided by predefined JD-R constructs.

Results: The analysis revealed 3 overarching domains comprising 9 main themes and 24 subthemes. On the gain path (job resources), AI empowered nurses through a workflow efficiency leap, clinical cognitive empowerment, and professional capital appreciation. Conversely, along the drain path (job demands), hidden costs were exposed, conceptualized as cognitive impediment, relational attrition, and digital involution driven by performance inflation and competitive perfectionism. The interplay between these pathways was perceived to be buffered by contextual mechanisms, specifically nurses' proactive coping strategies, professional boundary demarcation, and the provision of a cohesive organizational support architecture.

Conclusions: The impact of AI integration in nursing is not technologically deterministic. While AI provides valuable cognitive and operational support, it concurrently generates novel digital demands. To prevent AI from devolving into an occupational hazard, health care administrators must establish multidimensional life cycle AI governance, cultivate comprehensive AI literacy, and safeguard the irreplaceable humanistic core of clinical care.

(JMIR Nursing 2026;9:e100916) doi:10.2196/100916

KEYWORDS

AI; clinical nursing; qualitative research; Job Demands-Resources model; double-edged sword

Introduction

The global health care landscape is currently undergoing a digital transformation, driven by the rapid expansion of AI technologies. To address the chronic global shortage of nursing personnel and the increasing complexity of patient care, AI has emerged as a strategic imperative [1,2]. In mainland China, this technological wave is particularly pronounced, propelled by robust national policies aimed at constructing "smart hospitals" [3]. Consequently, clinical nursing practice has witnessed the extensive deployment of diverse AI applications. These range from specialized clinical algorithms—such as big data-driven early warning scores, intelligent workforce scheduling, and clinical decision support systems—to generative AI tools increasingly used for administrative tasks like drafting documentation [4-6]. As the largest professional workforce within the health care ecosystem, clinical nurses are positioned

XSL•FO
RenderX

at the forefront of this digital revolution, inevitably serving as the core end users of these multifaceted AI systems [7,8].

In line with the optimistic view that AI alleviates administrative burdens and improves decision-making [9], the actual deployment of AI-based systems has led to measurable reductions in documentation transcription time and costs: outpatient clinic letter completion time fell by nearly 8 days, and transcription savings totaled Aus $16,903 (Aus $1=US $0.71 as of May 27, 2026) [10]. However, frontline nursing reality presents a starkly different narrative. Emerging evidence reveals a complex double-edged sword effect [11,12]. While these metrics underscore AI's capacity to successfully automate certain routine tasks, its integration has spawned novel occupational hazards. Frontline nurses report experiencing alarm fatigue from hypersensitive predictive models, technostress stemming from complex system maintenance, and a pervasive sense of autonomy deprivation induced by ubiquitous digital surveillance [11-13]. Alarmingly, the unprecedented accessibility of AI tools has implicitly elevated organizational performance expectations, triggering a phenomenon of efficiency inflation and subsequent hyper-competition among peers [14,15]. This juxtaposition of technological promise and clinical reality provokes a critical inquiry: are these advanced algorithms genuinely empowering the nursing workforce or inadvertently entrapping them within a rigid, machine-dictated ecosystem?

To theoretically make sense of this seemingly contradictory clinical phenomenon, the Job Demands-Resources (JD-R) model serves as an optimal analytical lens [16]. The JD-R model posits that all psychosocial work characteristics can be classified into 2 overarching categories: job demands and job resources (Multimedia Appendix 1). Viewed through this framework, AI is not a neutral artifact but an active agent dynamically reshaping nursing work. On the one hand, AI can function as a robust job resource—streamlining workflows or providing cognitive support—thereby initiating a motivational process that enhances clinical efficacy. Conversely, unreliable algorithms or heightened performance expectations can morph AI into a stringent job demand. The resulting cognitive overload and socioemotional labor trigger a health impairment process, ultimately culminating in professional burnout. Thus, the JD-R model provides a nuanced architecture to deconstruct the bidirectional impacts of AI [17,18].

Despite the theoretical use of the JD-R model, a critical review of the literature reveals significant methodological and contextual gaps. To date, research concerning AI in nursing has been predominantly quantitative, frequently relying on technology acceptance models to assess willingness to use or focusing on algorithmic diagnostic accuracy [19,20]. While recent qualitative scholarship has begun examining AI perception among nursing leaders and researchers [6,21], in-depth qualitative inquiries explicitly centered on clinical nurses' heterogeneous interactions with diverse AI applications remain limited. Standardized questionnaires inherently fail to capture psychological undercurrents, such as the cognitive friction of verifying AI hallucinations or the subtle erosion of human-machine trust [22]. Furthermore, within the uniquely high-intensity health care context of mainland China, the unintended sociocultural consequences of AI integration—specifically the phenomena of efficiency inflation and professional involution—remain largely unexplored.

To bridge this knowledge gap, this study aims to deeply explore the "double-edged sword" effect of AI applications among clinical nurses, using directed qualitative content analysis (DQCA) [23] guided by the JD-R model. The novelty of this study is to theoretically deconstruct the bidirectional impacts of AI on clinical nurses and to identify buffering conditions, using the JD-R theoretical framework. Specifically, this qualitative inquiry has three objectives: (1) explicate the gain path by mapping how AI functions as an empowering job resource; (2) delineate the drain path by identifying how AI simultaneously acts as a novel digital job demand; and (3) uncover the perceived buffering conditions that navigate the interplay between these dual pathways. Ultimately, this study endeavors to provide a robust qualitative empirical foundation for health care organizations to develop more sustainable, human-centric AI integration strategies.

Methods

Study Design

A descriptive qualitative study design was adopted to deeply explore the lived experiences of clinical nurses interacting with AI. Given that this study is theoretically anchored in the JD-R model, we used a DQCA approach. DQCA is particularly appropriate when prior theory exists about a phenomenon but would benefit from further description or contextualization. This approach allowed us to deductively map nurses' experiences onto the predefined JD-R constructs while retaining the inductive flexibility to capture emerging, culturally specific phenomena. This study is reported in accordance with the Standards for Reporting Qualitative Research (SRQR) [24] guidelines.

Study Setting

Study Setting and Participant Context

The study was conducted in mainland China between November 2025 and March 2026. In contemporary Chinese health care, the practice scope of registered clinical nurses is inherently multidimensional, encompassing direct bedside care, clinical administration/quality improvement, and practice-based continuing education and scholarly research. Consequently, frontline nurses interact with a heterogeneous spectrum of AI applications, including embedded clinical AI systems—institutionally integrated, algorithm-driven tools designed for direct patient care, risk monitoring, and operational management (eg, early warning scoring systems and clinical decision support systems)—and generative AI tools driven by large language models (LLMs; eg, DeepSeek [Hangzhou DeepSeek Artificial Intelligence Basic Technology Research Co, Ltd], Doubao [Beijing Chuntian Zhiyun Technology Co, Ltd], or ChatGPT [OpenAI]). Participants were recruited across 8 general hospitals (tertiary and secondary) and 1 affiliated primary community health center in 4 municipalities/provinces (Beijing, Shandong, Guangdong, and Sichuan). The community facility was included as an integrated primary-care arm of a

XSL•FO
RenderX

regional tertiary health alliance to capture grassroots AI adoption. In this study, clinical nurses were defined broadly as registered nurses providing direct patient care, including those working in primary care settings, to reflect the full spectrum of AI deployment across different tiers of the health care system.

Participant Eligibility, Sampling, and Recruitment

A purposive sampling strategy framed by a maximum variation matrix was adopted to ensure broad coverage across key demographic and clinical dimensions. Inclusion criteria were as follows: (1) registered nurses holding a valid license; (2) currently engaged in direct clinical care with at least 1 year of clinical experience; and (3) having active, hands-on experience with at least one AI-based system—such as embedded clinical AI systems or generative AI tools—in their daily workflow for ≥3 months. Exclusion criteria included nurses exclusively in administrative roles without direct AI clinical application. Participants were recruited via professional nursing association networks and hospital department announcements across participating institutions. A total of 37 eligible nurses were approached; 2 declined due to clinical shift conflicts and 1 withdrew before the interview for personal reasons, yielding a final sample of 34 (completion rate: 91.9%) participants. To construct the sampling matrix, we initially recruited nurses varying in age, professional titles, educational backgrounds, and hospital tiers, aiming to capture the widest possible spectrum of routine AI interaction experiences. Building upon this maximum-variation framework, we then deliberately applied intensified sampling to 2 subgroups of particular theoretical interest: tertiary hospital nurses (n=26, 76.5%) and male nurses (n=13, 38.2%). Tertiary teaching hospitals serve as the primary innovation hubs for advanced AI deployment in China, and oversampling this group allowed us to capture dense, firsthand accounts of complex AI system integration. Similarly, male nurses—a demographic minority within the profession—were intentionally oversampled to ensure that their perspectives on technostress and human-AI interaction were not marginalized in the final analysis. This layered sampling design prioritizes both the breadth of routine experiences and the depth of theoretically critical cases. Enrollment continued until data saturation was achieved, defined as the point where no new codes or themes emerged from the last 3 consecutive interviews.

Procedures

Interviews were conducted by 2 qualitative researchers (XZ and JF) trained in advanced qualitative content analysis. Neither interviewer had prior personal, clinical, or administrative relationships with the participants. To ensure reflexivity, both interviewers maintained reflexive journals throughout the study to acknowledge, document, and bracket preexisting assumptions regarding the JD-R model (the detailed interview guide is provided in Multimedia Appendix 2). A total of 14 interviews were conducted face-to-face in private, quiet hospital conference rooms, while 20 were conducted via a secure online video conferencing platform (Tencent Meeting [Tencent]) to accommodate geographically distant participants across provinces. All interviews were conducted in Mandarin Chinese and lasted between 20 and 60 minutes. Field notes were recorded during and immediately after each interview to capture nonverbal cues, vocal hesitations, and emotional responses, which were subsequently integrated into transcript familiarization.

Analysis

Audio recordings were transcribed verbatim in Mandarin within 48 hours. Selected verbatim quotes were translated into English by a bilingual nursing researcher and back-translated by an independent native English academic editor to maintain conceptual and cross-language equivalence. Data analysis was managed using NVivo 20 software (QSR International) and followed the DQCA systematic steps: (1) preparation and familiarization—2 researchers independently read the transcripts multiple times alongside field notes to achieve deep immersion in the data; (2) deductive coding—initial coding categories were generated deductively from predefined JD-R constructs, and transcripts were coded by assigning text passages to these predefined categories; (3) inductive coding—data that could not be categorized into the initial JD-R model were assigned new codes inductively using explicit rules; for instance, statements describing technology-driven peer hyper-competition and artificially escalated management performance baselines were inductively coded under digital involution. To ensure coding reliability, 2 coders independently coded an initial batch of 6 transcripts; (4) theme refinement, disagreement resolution, and rigor—the research team held regular consensus meetings to compare codes, resolve discrepancies, and abstract the codes into main themes and subthemes. Discrepancies were discussed until 100% agreement was reached. Theoretical saturation was audited through a cumulative codebook; code generation stabilized at Participant 31, and the final 3 consecutive interviews produced zero new codes or subthemes, confirming data saturation.

Ethical Considerations

Ethical approval for this study was obtained from the Ethics Committee of Beijing Hospital (approval 2024BJYYEC-KY203-02). Before data collection, all prospective participants were provided with a detailed information sheet outlining the study's purpose, procedures, and their rights. Written informed consent was obtained from each participant before the interviews commenced. Participants were explicitly informed that their participation was completely voluntary and that they had the right to withdraw from the study at any time without penalty. To address ethical and privacy concerns regarding technology use, the research team explicitly inquired about data security practices during the interviews. All participants who used noninstitutional, general-purpose AI tools reported manually executing strict deidentification protocols (eg, stripping patient names, identification numbers, specific dates, and institutional identifiers) prior to any text or data entry. Disclosures of unauthorized or unapproved AI practices were treated with strict research confidentiality, framed nonpunitively, and analyzed as systemic indicators of unmet operational efficiency demands rather than individual misconduct. To strictly protect participant confidentiality and anonymity, all audio recordings and transcripts were stored securely on password-protected devices. Each participant was assigned a pseudonym, and specific identifying details regarding their

XSL•FO
RenderX

employment were carefully modified or redacted to ensure they remained unidentifiable in the presentation of the findings.

Trustworthiness

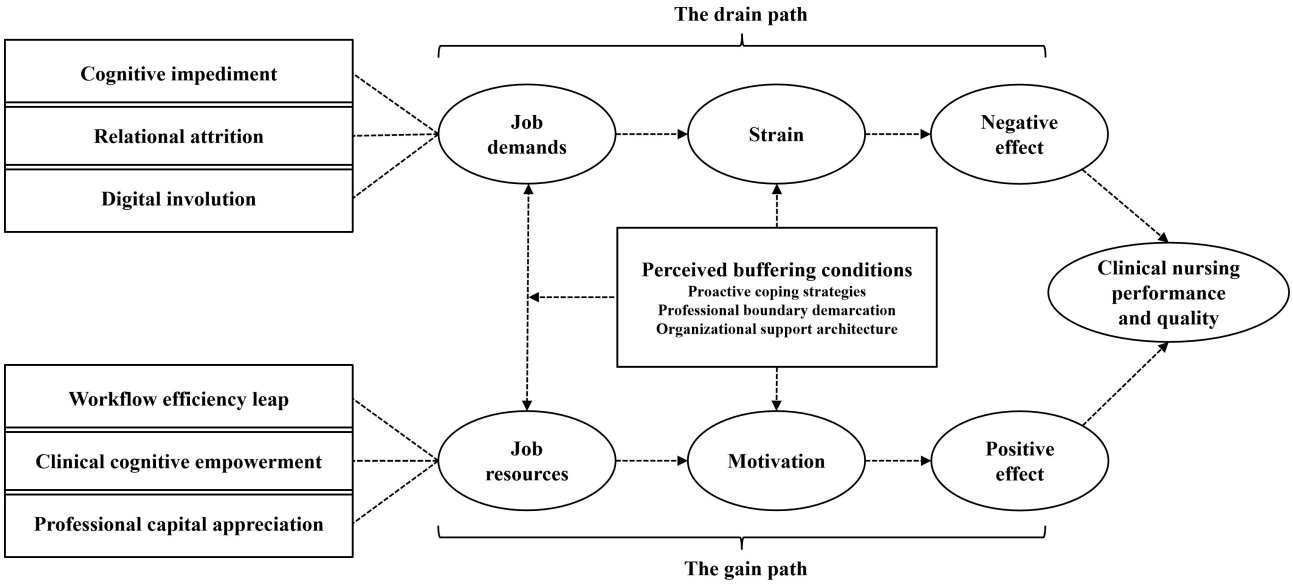
To ensure methodological rigor, we adhered to Lincoln and Guba's evaluative criteria: (1) credibility—member checking was performed by returning a summary of the synthesized themes to 5 participants to verify whether the findings accurately reflected their realities. Additionally, peer debriefing was conducted with a senior qualitative researcher to challenge and refine the analytical interpretations. (2) Transferability—thick descriptions of the study setting, participant demographics, and contextual factors (eg, China's specific clinical environment) were provided to allow readers to assess the applicability of the findings to other contexts. (3) Reliability—a comprehensive audit trail was maintained, documenting all methodological decisions, coding dictionaries, and analytical memos. Two independent coders performed the analysis, and intercoder agreement was continuously negotiated. (4) Confirmability—the researchers practiced continuous reflexivity by keeping a reflexive journal to acknowledge and bracket their preexisting assumptions regarding AI and the JD-R model, ensuring that the findings were deeply grounded in the participants' narratives rather than the researchers' biases.

Results

Participant Characteristics

A total of 34 clinical nurses from various departments and hospital tiers were recruited through purposive sampling. The demographic profile of the participants is summarized in Multimedia Appendix 3. The participants' ages ranged from 23 to 43 years (mean age 30.65, SD 5.56 y), and their nursing experience spanned from 1 to 22 years (mean experience 8.12, SD 5.48 y). The sample consisted of 21 (61.8%) females and 13 (38.2%) males. Regarding educational background, 23 (67.6%) participants held an undergraduate degree, 7 (20.6%) held a postgraduate degree, and 4 (11.8%) had a junior college diploma or below. In terms of professional titles, the majority were intermediate-level nurses (n=19, 55.9%), followed by junior-level (n=11, 32.4%) and senior-level nurses (n=4, 11.8%). Participants were drawn from diverse clinical settings, including surgery (n=14, 41.2%), internal medicine (n=12, 35.3%), emergency (n=4, 11.8%), and intensive care units (n=4, 11.8%). Most participants (n=26, 76.5%) were recruited from tertiary hospitals, with the remainder from secondary (n=7, 20.6%) or community (n=1, 2.9%) health care facilities.

Across the sample, nurses interacted with a dual ecosystem of AI technologies, combining hospital-integrated clinical AI systems (eg, early warning scoring systems, clinical decision support systems, risk prediction systems, and smart infusion pumps) with personally accessed generative AI tools (eg, DeepSeek, Doubao, ChatGPT, and Kimi [Moonshot AI]). Hospital-sanctioned clinical AI systems were characterized by high daily workflow integration for direct bedside care following formal institutional onboarding, whereas generative AI tools were predominantly self-taught and used for administrative drafting, literature synthesis, and health education content creation (see Multimedia Appendix 4 for more details).



Overview of the Findings

Thematic Structure of the Findings

Through DQCA guided by the JD-R framework, we identified 3 overarching domains comprising 9 main themes and 24 subthemes that illustrate the complex double-edged sword effect of AI application in clinical nursing (Figure 1). Specifically, the gain path (job resources) demonstrates the empowering potential of AI by facilitating a workflow efficiency leap, providing clinical cognitive empowerment, and fostering professional capital appreciation. Conversely, the drain path (job demands) highlights the hidden and continuous costs of AI integration, conceptualized as perceived cognitive impediment, relational attrition that challenges humanistic empathy, and digital involution driven by performance inflation and competitive pressures. Furthermore, the interplay between these perceived gains and demands is contextualized by key perceived buffering conditions, specifically nurses' proactive coping strategies, strict professional boundary demarcation, and the presence of a supportive organizational support architecture. The detailed thematic coding tree is presented in Multimedia Appendix 5.

XSL•FO
RenderX

Figure 1. Qualitative conceptual map of the double-edged sword effect of AI application among clinical nurses under the Job Demands-Resources (JD-R) framework.

Domain 1: AI as a Job Resource (the Gain Path)

AI emerged as a robust job resource for clinical nurses, triggering a motivational process. By interacting with various AI systems, nurses extracted perceived empowerment, which manifested across 3 distinct themes: workflow efficiency leap, clinical cognitive empowerment, and professional capital appreciation.

Theme 1: Workflow Efficiency Leap

In this study, workflow efficiency leap is defined as structural optimization and operational acceleration of daily nursing duties through AI automation, enabling nurses to transition from administrative overextension to streamlined task execution. Participants frequently articulated how AI integration fundamentally remodeled their daily operations across 3 subthemes: documentation automation, task cycle reduction, and team synergy strengthening.

Subtheme 1: Documentation Automation

Nurses reported an alleviation of administrative burdens driven primarily by generative AI tools. Rather than expending energy on repetitive typing and formatting, nurses used AI to structure scattered data and polish professional communication. For instance, generative AI tools provided vital support for cross-lingual writing, refining the phrasing of workplace correspondence, and rapidly summarizing lengthy literature. This capability lowered the barrier to content creation and eased the cognitive friction associated with writer's block. As nurse N10 illustrated: "if I want to create an outline myself, it might take a bit longer. But if AI helps me, it only takes one or two minutes, or even just twenty or thirty seconds" (see Multimedia Appendix 5 for the full dataset).

Subtheme 2: Task Cycle Reduction

Both embedded clinical AI systems (eg, automated electronic health record data extraction) and generative AI tools acted as perceived accelerators across varied nursing duties. Participants noted a substantial reduction in task initiation time and overall completion cycles. Efficient data retrieval algorithms replaced traditional, time-consuming manual searches. By handling these low-value, repetitive tasks, AI provided notable psychological relief, reducing the subjective intensity and time pressure of administrative duties. As nurse N24 noted: "The main advantage is that it's extremely efficient. You just send it your key images, data, and requirements, and it generates the output for you. It's much more efficient than searching online yourself and analyzing or comparing things one by one; it's very fast and convenient. It has reduced the amount of time I spend" (see Multimedia Appendix 5 for the full dataset).

Subtheme 3: Strengthening Team Synergy

Beyond individual use, embedded clinical AI systems (such as intelligent shift scheduling software and task distribution platforms) functioned as collaborative catalysts. These tools facilitated transparent role assignments and optimized team task distribution. In scenarios requiring collective decision-making, generative AI tools enabled the rapid integration of multidisciplinary information. Automated scheduling systems enhanced team synchronization and facilitated perceived collective outputs. As nurse N3 stated: "During group discussions, we can use AI to organize the questions we need to answer and better establish our future direction" (see Multimedia Appendix 5 for the full dataset).

Theme 2: Clinical Cognitive Empowerment

This theme is conceptualized as the intellectual scaffolding provided by AI, which dynamically bridges individual knowledge gaps, reinforces clinical decision-making logic, and safeguards patient care in high-stakes clinical environments. In these complex settings, AI transcended its role as a mere physical tool to become an indispensable cognitive partner through instant knowledge replenishment, thinking logic scaffolding, and clinical safety safeguarding.

Subtheme 4: Instant Knowledge Replenishment

Nurses perceived generative AI tools and integrated clinical decision support systems as an on-demand knowledge repository

XSL•FO
RenderX

that was particularly crucial during emergencies or unfamiliar cases. The systems provided rapid access to specialized clinical knowledge, complex pharmacological data (eg, drug interactions), and evidence-based guidelines. This instant access effectively masked experience deficits among junior nurses. As nurse N6 noted: "I use AI to organize and recall anatomical positions and functions; after sorting it out, I have a general idea of the clinical purpose and direction" (see Multimedia Appendix 5 for the full dataset).

Subtheme 5: Thinking Logic Scaffold

When confronting cognitive bottlenecks, such as complex case analyses or practice-based academic reflection, generative AI tools served as a cognitive coach. They provided structural frameworks, established logical connections between disparate symptoms, and assisted in structuring care plans. Participants emphasized that AI stimulated secondary reflection and expanded thinking dimensions. As nurse N8 described: "When I'm stuck on how to approach something, I might need AI to point the way. For example, when writing a report for the first time, I needed AI to give me a logical pivot. It also told me how to structure the logic of the text" (see Multimedia Appendix 5 for the full dataset).

Subtheme 6: Clinical Safety Safeguarding

Embedded clinical AI systems (eg, early warning scoring models and closed-loop smart infusion pumps) acted as vigilant partners in direct patient care. By monitoring microphysiological trends, predictive models offered early warnings for clinical deterioration, effectively reducing continuous vigilance fatigue. Automated assistance in high-risk procedures was perceived to enhance clinical safety monitoring and foster technological trust. As nurse N23 noted: "The intelligent early warning system mainly monitors patients' vital signs... If any data is abnormal, it immediately alerts us so we can respond quickly" (see Multimedia Appendix 5 for the full dataset).

Theme 3: Professional Capital Appreciation

Professional capital appreciation refers to the long-term enrichment of nurses' psychological well-being, digital competencies, and occupational value, which fosters professional self-efficacy and enables a recentering on humanistic patient care. The use of AI generated these secondary benefits for nurses' career trajectories through emotional energy replenishment, cross-boundary skill expansion, and core value regression.

Subtheme 7: Emotional Energy Replenishment

Delegating routine tasks to both generative AI tools and embedded clinical AI systems generated significant positive emotional energy. Nurses reported a heightened sense of control over their work pace and a reduction in digital anxiety. The reliable, on-demand nature of AI assistance served as a psychological buffer during overwhelming workloads. As nurse N4 shared: "Even though it's complicated, we still have AI, right ?... It boosts my confidence in my work. With that confidence, I'm less likely to be bothered by difficulties" (see Multimedia Appendix 5 for the full dataset).

Subtheme 8: Cross-Boundary Skill Expansion

Generative AI tools functioned as accessible tutors that lowered thresholds for acquiring new digital competencies. Nurses used AI to bridge knowledge gaps, learn nursing research methodologies (eg, SPSS Statistics [Version 20.0; IBM Corp] operations and statistical workflows), and rapidly acquire digital content creation skills for patient education (eg, short video scripts). As nurse N33 shared: "It forced me to learn data analysis. Before, I just followed orders; now, I interpret AI-generated reports and analyze chronic disease trends in my district... It transformed me from an executor into a manager" (see Multimedia Appendix 5 for the full dataset).

Subtheme 9: Core Value Regression

A value-driven expectation emerged from the data. By absorbing trivial administrative and physical tasks, AI implicitly redirected nurses' finite attention back to the essence of nursing: direct patient care and complex emotional labor. Participants expressed future aspirations for advanced AI—such as intelligent ward-roaming robots or automated health education loops—to fully eradicate manual drudgery, thereby allowing them to reclaim their professional identity as empathetic caregivers. As nurse N1 stated: "It can take over more mechanical tasks, such as documentation or monitoring, allowing nurses to focus more on patient psychological care and complex clinical management" (see Multimedia Appendix 5 for the full dataset).

Domain 2: AI as a Job Demand (the Drain Path)

Viewed through the JD-R theoretical lens, the deployment of AI was not entirely benign. Instead, it introduced novel and complex job demands that triggered a potential health impairment process. Participants highlighted a perceived drain path, where the superficial alleviation of physical tasks was counterbalanced by subjective psychological, cognitive, and systemic burdens.

Theme 4: Cognitive Impediment

While AI promised cognitive relief, the unreliability and complex operational logic of current algorithms generated new dimensions of mental load, transforming nurses from care providers into algorithmic supervisors.

Subtheme 10: Verification Overload

A pervasive narrative was the persistent threat of algorithmic unreliability, which manifested distinct cognitive burdens across AI classes. For generative AI tools, nurses faced the threat of AI hallucinations (fabricated medical citations or inaccurate pharmacological data); for embedded clinical AI systems, nurses struggled with hypersensitive algorithms that caused frequent false alarms. Both mandated compulsory cross-verification, increasing cognitive fatigue and offsetting initial efficiency gains. As nurse N1 noted, "In individual diagnosis and treatment-related aspects, the results can vary significantly... We still need to cross-check with clinical experience or other case studies" (see Multimedia Appendix 5 for the full dataset).

Subtheme 11: Interaction Fatigue

The human-machine interaction associated with generative AI systems constituted a notable hidden demand. Participants described the high cognitive cost of prompt engineering,

XSL•FO
RenderX

continuously adjusting, refining, and debugging instructions to align AI outputs with complex clinical realities or institutional frameworks. This cycle of trial and error interrupted workflows. As nurse N5 illustrated: "Initially, when giving instructions to AI, it often didn't understand my intent, requiring constant refinement. Ambiguities inevitably arise, necessitating repeated questioning—this creates early-stage burdens"(see Multimedia Appendix 5 for the full dataset).

Subtheme 12: Mental Dependency

Long-term exposure to both generative AI tools and embedded clinical AI systems generated anxiety regarding professional deskilling. Nurses expressed deep concerns over cognitive blunting, fearing that outsourcing clinical reasoning, calculations, and diagnostic structuring to algorithms would atrophy their independent critical thinking and intuitive clinical judgment. As nurse N3 noted: "I unconsciously default to AI for task completion, bypassing independent thinking—this gradual reliance dulls cognitive engagement" (see Multimedia Appendix 5 for the full dataset).

Theme 5: Relational Attrition

The insertion of algorithms into the health care ecosystem disrupted traditional human dynamics, generating novel interpersonal conflicts and threatening the empathetic core of nursing practice.

Subtheme 13: Interpretive Labor

The democratization of consumer-accessible generative AI tools meant that patients and families frequently used these systems for self-diagnosis. Frontline nurses were forced to absorb substantial amounts of new interpretive labor—deconstructing AI-generated misinformation, managing patient anxiety, and rebuilding trust. As nurse N30 stated: "Patients and families create challenges by consulting unreliable online sources... This undermines our health education efforts" (see Multimedia Appendix 5 for the full dataset).

Subtheme 14: Care Dehumanization

Participants harbored deep apprehensions regarding technology-mediated alienation caused by standardized algorithmic care pathways and automated communication scripts. Nurses feared a loss of humanistic care, perceiving algorithmic reliance as an emotional barrier that reduced holistic nursing to rigid, machine-dictated transactions. As nurse N12 noted, "Compared to humans, it's deficient in humanistic care—a cornerstone of our profession" (see Multimedia Appendix 5 for the full dataset).

Subtheme 15: Professional Alienation

Embedded clinical AI systems (eg, performance-tracking algorithms and automated shift scheduling) and rapid technology iterations fostered professional insecurity. Senior staff facing the digital divide experienced anxiety regarding displacement and feeling managed by algorithms, which eroded their clinical agency. As nurse N23 described: "My greatest fear is AI wholly supplanting nursing roles, eliminating job opportunities" (see Multimedia Appendix 5 for the full dataset).

Theme 6: Digital Involution

In the highly competitive context of the modern health care system, digital involution is conceptualized as a sociotechnical paradox wherein technology-driven efficiency artificially inflates performance expectations, locking nurses into a cycle of hyper-competition, perfectionism, and invisible labor without proportional gains in well-being. Specifically, the integration of AI catalyzed unintended structural pressures across 3 interrelated dimensions: performance inflation, competitive perfectionism, and workload expansion.

Subtheme 16: Performance Inflation

The accessibility and speed of generative AI tools lowered the threshold for complex administrative and quality-improvement deliverables (eg, report synthesis or presentation design), which paradoxically triggered performance inflation. Management implicitly raised baseline standards, demanding perfect deliverables and forcing nurses into a cycle of continuous overperformance. As nurse N33 illustrated: "Management increasingly judges quality by numbers rather than substance. Quantity gradually overshadows quality focus, and performance benchmarks keep escalating." (see Multimedia Appendix 5 for the full dataset).

Subtheme 17: Competitive Perfectionism

The accessibility of AI-generated content fostered an environment of intensified peer comparison. Nurses felt compelled to produce flawlessly polished materials to maintain their professional standing, leading to a state of competitive perfectionism. This subtheme highlights how AI-driven high standards became the new minimum requirement, forcing individuals to invest excessive cognitive effort into refining AI outputs to avoid being outperformed by colleagues. As nurse N23 noted: "I have to spend time after work every day learning related knowledge, and I feel a lot of pressure. Before, when we wrote health education materials, 'good enough' was fine. But now with AI, the requirements keep getting higher, the quality keeps improving — it's very competitive" (see Multimedia Appendix 5 for the full dataset).

Subtheme 18: Workload Expansion

Contrary to labor-saving promises, findings reveal a paradoxical expansion of invisible digital labor across both technology classes. This includes troubleshooting embedded system errors, performing redundant dual-entry processes between legacy systems and AI platforms, and debugging generative AI outputs. As nurse N7 noted: "Nurses haven't had responsibilities reduced by AI; instead, we've gained the added duty of monitoring AI for malfunctions" (see Multimedia Appendix 5 for the full dataset).

Domain 3: Perceived Buffering Conditions for Navigating the Dual-Edged Sword Effect of AI

Within the JD-R model, the transition of AI from a potential job demand back to an empowering job resource is heavily contingent on specific buffering conditions. The analysis revealed that nurses actively and passively used various moderating mechanisms to navigate the double-edged nature of AI. These mechanisms, which mitigate the health impairment

XSL•FO
RenderX

process (ie, the strain path where high job demands deplete emotional and cognitive energy, leading to burnout) and enhance the motivational process (ie, the gain path where abundant job resources foster work engagement and self-efficacy), are conceptualized into 3 core themes: proactive coping strategies, professional boundary demarcation, and organizational support architecture.

Theme 7: Proactive Coping Strategies

Nurses did not remain passive recipients of technological outputs; instead, they engaged in highly proactive behavioral crafting to harness AI's use while neutralizing its risks.

Subtheme 19: Critical Verification Execution

To combat generative AI hallucinations and predictive model false alarms, nurses developed rigorous cross-verification habits. Rather than blindly trusting algorithmic outputs, participants used multisource cross-verification strategies, treating AI-generated content purely as a preliminary draft rather than definitive evidence. This active cognitive filtering served as a crucial buffer, preventing machine errors from translating into clinical incidents. As nurse N6 illustrated: "If findings contradict my foundational knowledge, I reevaluate and reassess AI's conclusions" (see Multimedia Appendix 5 for the full dataset).

Subtheme 20: Strategic Interaction Mastery

Nurses ameliorated interaction friction, specifically when using generative AI tools, by mastering prompt engineering, strategic data feeding (providing authentic clinical contexts), and task-technology calibration (delegating low-risk administrative drafting to AI while reserving complex clinical decisions for traditional human pathways). As nurse N15 shared: "Command refinement is key—iterative tweaks align outputs with needs" (see Multimedia Appendix 5 for the full dataset).

Theme 8: Professional Boundary Demarcation

A robust psychological and professional defense mechanism emerged as nurses deliberately fortified their occupational identity against technological encroachment.

Subtheme 21: Role Positioning Clarity

Participants conceptualized both generative AI tools and embedded clinical AI systems strictly as high-capacity subordinate assistants or information aggregators, vehemently rejecting AI as an autonomous decision-maker. Recognizing AI's lack of genuine empathy insulated nurses from replacement anxiety. As nurse N26 noted: "A textual assistant. For reference and support—nothing more" (see Multimedia Appendix 5 for the full dataset).

Subtheme 22: Clinical Agency Retention

Nurses preserved clinical autonomy by insisting on the irreplaceable nature of physical touch and empathetic care. In clinical decision-making, they adopted a "think first, consult second" paradigm, ensuring human reasoning framed the clinical strategy. As nurse N6 stated: "*I adhere to my own logic—AI won't override my reasoning. Critical thinking is non-negotiable. With independent thought, AI becomes a tool, not a puppeteer* "(see Multimedia Appendix 5 for the full dataset).

Theme 9: Organizational Support Architecture

The organizational environment served as a macroscopic macroregulator. The presence or absence of institutional backing dictated whether AI integration felt like an empowering resource or a competitive burden.

Subtheme 23: Systemic Resource Provision

Participants expressed a need for hospitals to transcend fragmented usage by deploying unified, institutionally sanctioned, vertically integrated medical AI platforms (eg, specialized medical LLMs trained on validated clinical guidelines). Centrally provided platforms lower cognitive thresholds and alleviate security concerns. As nurse N3 noted: "Hospitals could consolidate databases... Institution-led AI platforms would streamline retrieval" (see Multimedia Appendix 5 for the full dataset).

Subtheme 24: Capacity Building Support

Nurses emphasized the need for structured organizational training focusing on underlying algorithmic logic (for embedded clinical AI systems) and prompt structuring and error avoidance (for generative AI tools), backed by clear institutional policies and ethical boundaries. As nurse N3 described: "If hospitals adopt AI, they should develop structured teaching programs" (see Multimedia Appendix 5 for the full dataset).

Discussion

Summary of Principal Findings

Guided by the JD-R model, this qualitative study provides a nuanced qualitative empirical understanding of the double-edged sword effect of AI integration among frontline clinical nurses. Our findings demystify AI from being a unilaterally empowering artifact, revealing it instead as a highly dynamic agent that concurrently activates distinct gain and drain pathways. On the gain path, AI functions as a robust job resource that initiates a motivational process, characterized by a substantial workflow efficiency leap, critical clinical cognitive empowerment, and the subsequent appreciation of professional capital. Conversely, the drain path exposes the hidden sociotechnical costs where AI operates as a novel, multifaceted job demand. These demands manifest as cognitive friction, relational strain that threatens traditional empathetic care, and a pervasive systemic involution driven by technology-induced efficiency inflation. Crucially, our qualitative findings suggest that this technological paradox is not perceived as deterministic. Rather than demonstrating tested causal moderation, our data illustrate that the lived interplay between AI-driven resources and demands is contextualized by key perceived buffering conditions: nurses' proactive coping strategies, their rigorous professional boundary demarcation to preserve clinical agency, and the provision of a cohesive organizational support architecture.

The Double-Edged Sword Effect: Deconstructing the Gain and Drain Pathways

The Gain Path

Consistent with the motivational pathway of the JD-R model, our findings validate that AI serves as a potent perceived job

XSL•FO
RenderX

resource, initiating empowerment across 3 progressive dimensions: operational workflow, clinical cognition, and professional capital. First, regarding operational execution, our findings corroborate historical health information technology literature that emphasizes the physical and temporal benefits of automation [25]. We demonstrate a substantial workflow efficiency leap, where disaggregated technology classes yield distinct operational resources: generative AI tools streamline documentation automation and literature retrieval, whereas embedded clinical AI systems enhance shift scheduling and team synergy. These observations converge with recent qualitative scholarship, highlighting AI's capacity to alleviate administrative burdens and optimize workflow management [6,21,26]. Beyond routine automation, AI provides critical clinical cognitive empowerment. Specifically, embedded clinical AI systems (eg, early warning scores) act as safety sentinels, whereas generative AI tools function as on-demand cognitive tutors that bridge knowledge gaps and scaffold clinical reasoning. This positions AI as an active adjunct to human cognition [27-29], directly boosting nurses' self-efficacy [30,31] and rendering complex tasks manageable [32]. Ultimately, this operational and cognitive synergy fosters professional capital appreciation. By delegating mundane tasks to algorithms, nurses restore emotional resources, acquire cross-boundary digital skills, and experience a "core value regression"—redirecting finite attentional capacity back to the irreplaceable, humanistic core of patient care.

The Drain Path

Despite the optimistic narrative surrounding AI empowerment, our study uncovers a perceived health impairment process driven by novel digital demands. Consistent with Chuang et al [33], who demonstrated the dual impact of AI on work and life well-being under the JD-R model, our finding reinforces the model's suitability for unpacking the paradoxical effects of AI in clinical nursing contexts. A critical finding in this study is the manifestation of an AI productivity discrepancy rooted in cognitive impediment, which manifests through distinct technological mechanisms. While AI theoretically accelerates task completion, this temporal advantage is frequently neutralized by hidden cognitive loads. For generative AI tools, cognitive load stems from the threat of algorithmic hallucinations and omissions, forcing nurses into tedious prompt engineering and multisource verification; for embedded clinical AI systems, cognitive strain is driven by hypersensitive false alerts and alert fatigue [34]. As our data suggests, cognitive workload has not disappeared; it has merely shifted from primary content creation to secondary content verification. This verification pressure is further compounded by the psychological risk of automation bias (uncritical overreliance on AI outputs) versus the cognitive friction of overriding false alerts.

Furthermore, an important finding is that within the highly competitive environment of contemporary health care, the widespread accessibility of generative AI tools has inadvertently driven performance inflation. As AI lowers the technical barriers for producing polished administrative or quality-improvement work, nursing management implicitly raises baseline expectations. While prior literature often conceptualizes technological stress as individual operational difficulty, our findings uncover a novel sociotechnical phenomenon—digital involution—wherein frontline nurses are locked into a cycle of competitive perfectionism and invisible workload expansion (eg, dual-entry validation and prompt debugging). When combined with the interpretive labor required to bridge the gap between AI misinformation and patient understanding amid ambiguous legal responsibility frameworks, these demands constitute a substantial source of technostress. If left unaddressed, this invisible surge in task intensity, coupled with professional alienation and the fear of occupational displacement, threatens the long-term sustainability of the nursing workforce. These findings suggest that without organizational interventions to decouple AI efficiency from ever-increasing performance quotas, the double-edged sword of AI may inadvertently accelerate burnout rather than alleviate it.

Perceived Buffering Conditions: Navigating Demands and Resources

Another significant finding is that our qualitative findings illustrate how nurses perceive AI as shifting between a resource and a demand depending on contextual buffering conditions at individual, professional, and organizational levels. At the micro level, nurses exercise agency through proactive coping and strategic interaction proficiency [34]—tailoring prompt engineering for generative LLMs while maintaining vigilant verification for embedded clinical alerts. By selectively delegating routine tasks to algorithms while retaining high-stakes clinical judgments, practitioners optimize operational gains while mitigating cognitive risks. This resilience is anchored in professional boundary demarcation, where AI is positioned strictly as an auxiliary tool rather than an autonomous decision-maker. Such role clarity, combined with an emphasis on humanistic care, serves as a cognitive buffer against occupational replacement anxiety and technological alienation.

However, individual resilience alone is insufficient to sustain this balance. Organizational support architectures serve as the critical fulcrum. To prevent a cycle in which efficiency gains from technology inadvertently trigger escalating performance quotas, health care institutions must provide systemic resources. These include institutionally sanctioned, vertically integrated medical AI models (to eliminate the privacy and hallucination risks of generic public chatbots) and structured capacity-building programs focused on algorithmic logic, prompt calibration, and error avoidance. Ultimately, the synergy between individual professional agency and institutional scaffolding helps explain whether AI is perceived as an occupational hazard or a sustainable clinical resource.

Implications for Nursing Management and Practice

The findings of this study offer critical and actionable insights for health care administrators seeking to sustainably integrate AI into clinical nursing practice without exacerbating burnout.

First, to mitigate the cognitive impediments and legal anxiety associated with algorithmic hallucinations and false alerts, nursing administrators should actively collaborate with interprofessional hospital leadership to co-design and implement nursing-specific AI governance guidelines within the broader

XSL•FO
RenderX

organizational framework [35]. For instance, nurse leaders can establish clear operational protocols that delineate permissible AI boundaries—such as defining mandatory "human-in-the-loop" verification steps for AI-predictive risk alerts and establishing explicit guidelines that mandate clinical nurse sign-off before AI-generated documentation or care plans are finalized in patient records.

Second, health care institutions must establish a comprehensive, multidimensional AI life cycle governance framework encompassing people, processes, technology, and operations [36]. Rather than assuming that adopting institutionally sanctioned, vertically integrated medical AI models automatically eliminates privacy or reliability risks, hospital management must recognize that technological infrastructure requires robust operational oversight. Centrally funded and domain-specific clinical AI tools (eg, algorithms trained on validated guidelines and secure electronic health record databases) should be deployed alongside strict operational protocols: enforcing mandatory data deidentification, embedding clear digital audit trails, defining legal liability boundaries, and establishing explicit escalation procedures when algorithmic outputs conflict with human clinical judgment. Crucially, organizational policies must safeguard against automation bias and model drift by institutionalizing mandatory human oversight and conducting routine audits of joint human–AI system performance under both optimal and misleading AI outputs.

Third, the paradigm of capacity building support must evolve. Nursing education and continuous professional development programs should move beyond rudimentary software tutorials to cultivate comprehensive AI literacy. This involves equipping nurses with advanced prompt engineering techniques for generative AI tools, algorithmic awareness for embedded clinical AI systems, and standardized critical verification protocols.

Finally, to dismantle the escalating cycle of performance demands driven by technology, management must fundamentally recalibrate performance evaluation metrics. It is imperative that leadership ensures the temporal resources liberated by AI are channeled into a core value regression. Specifically, time saved should be redirected back to direct patient care and empathetic engagement rather than being absorbed by artificially inflated administrative workloads or escalating performance targets.

Strengths, Limitations, and Future Research

A key strength of this study lies in its robust theoretical anchorage within the JD-R model, providing theoretically grounded qualitative insights into the lived experiences of frontline nurses navigating AI. However, several limitations warrant acknowledgment. First, as a cross-sectional qualitative content analysis, this study captures participants' perceived experiences and subjective reflections; it cannot establish statistical causality, measure objective clinical performance/safety outcomes, or formally test quantitative mediation or moderation pathways. Second, because data were collected exclusively within mainland China, specific culturally embedded psychosocial dynamics may lack statistical generalizability and could manifest differently across diverse global health care ecosystems. Third, the reliance on digital recruitment strategies and voluntary participation may introduce self-selection bias toward hyper-users or tech-savvy individuals. Consequently, future research should prioritize the development and validation of psychometric instruments to quantitatively test these newly identified AI-driven JD-R pathways within larger, representative populations. Furthermore, longitudinal designs and cross-cultural comparative studies are strongly recommended to continuously track the enduring impacts of algorithmic integration on occupational well-being, evaluate joint human–AI system performance under both optimal and misleading AI conditions, and elucidate how varying organizational support architectures globally buffer these complex technological demands.

Conclusions

This qualitative study provides a nuanced theoretical unpacking of the double-edged sword effect of AI in clinical nursing through the lens of the JD-R model. While AI acts as an empowering job resource by facilitating perceived efficiency gains and clinical cognitive empowerment, it simultaneously introduces notable digital job demands. These demands manifest primarily as cognitive impediments stemming from verification overload, relational attrition challenging the empathetic core of nursing, and the psychological exhaustion induced by digital involution. Crucially, our findings illustrate that the trajectory of AI integration is not technologically deterministic. Instead, the lived interplay between AI-driven resources and demands is contextualized by key perceived buffering conditions: nurses' proactive coping strategies, rigorous professional boundary demarcation, and the provision of a robust organizational support architecture. To prevent AI from devolving into an occupational hazard, health care administrators must transcend the mere deployment of algorithms. By establishing comprehensive life cycle AI governance, providing advanced AI literacy training, and safeguarding the irreplaceable humanistic essence of the profession, organizations can sustainably harness AI to empower the nursing workforce and elevate patient care in the digital era.

Acknowledgments

The authors disclose that DeepSeek (DeepSeek AI, Hangzhou, China) was the only generative AI tool used, and it was used solely for language editing and readability improvement during the preparation of this manuscript. Specifically, DeepSeek was used to refine language expression, improve readability, and polish the English writing. No AI-generated content was incorporated into the final manuscript. All AI-assisted outputs were critically reviewed, fact-checked, and substantially revised by the authors. The authors take full responsibility for the accuracy, originality, integrity, and all content in the manuscript, including all references and citations.

Abstract

Background: Large language models (LLMs) have shown promising results on Japanese national medical and nursing examinations. However, no study has evaluated LLM performance on the Japanese Public Health Nurse National Examination, which requires specialized knowledge in community health and public health nursing practice.

Objective: This study aimed to compare the performance of multiple LLMs on the Japanese Public Health Nurse National Examination and evaluate their potential utility in public health nursing education.

Methods: Three LLMs were evaluated: GPT-4o, Claude Opus 4, and Gemini 2.5 Pro. All 110 questions from the 111th Public Health Nurse National Examination were administered using standardized prompts. Questions were classified by format (text vs figure or calculation), content (general vs situational), and selection type (single vs multiple choice). Accuracy rates and 95% CIs were calculated, with statistical comparisons performed using chi-square tests.

Results: All LLMs exceeded the passing criterion (60%). The accuracy rates were as follows: 85.5% (94/110) for GPT-4o (95% CI 77.5% - 91.5%), 91.8% (101/110) for Claude Opus 4 (95% CI 85.0% - 96.2%), and 92.7% (102/110) for Gemini 2.5 Pro (95% CI 86.2% - 96.8%). No significant differences were found among the LLMs (P>.99). However, all models showed lower accuracy on multiple-choice questions than on single-choice questions, with significant intramodel differences observed for GPT-4o (10/16, 62.5% vs 82/92, 89.1%; P=.01) and Claude Opus 4 (12/16, 75% vs 87/92, 94.6%; P=.03).

Conclusions: LLMs demonstrated high performance on a public health nursing examination but showed limitations in complex reasoning requiring multiple-choice selection. These findings suggest the potential for LLM use as educational support tools while highlighting the need for cautious implementation in specialized nursing education.

large language models; public health nursing; licensure; nursing; artificial intelligence; AI; education

Introduction

With advances in artificial intelligence (AI), large language models (LLMs) have gained attention in various fields. High-performance LLMs have been developed, including GPT-3.5, GPT-4, Anthropic's Claude, and Google's Gemini [1-3], which have demonstrated their ability to generate contextually appropriate responses to complex questions. In Japan, the capabilities of these models have been evaluated using questions from the national medical and nursing examinations. Liu et al [4] compared GPT-4o, GPT-4, Claude Opus 3, and Gemini 1.5 Pro using Japan's national medical examinations and found that GPT-4o achieved the highest accuracy rate (89.2%) and intermodel performance depending on the subject area and question format. Takagi et al [5] also found that GPT-4 significantly outperformed GPT-3.5 in national medical examinations (79.9% vs 50.8%), revealing significant performance gaps between model generations. Taira et al [6] reported that LLM accuracy declined for questions about pharmacology, social welfare, and related legal regulations on national nursing examinations, suggesting limitations in responding to questions requiring specialized knowledge and institutional understanding. These findings demonstrate LLM utility and associated challenges in Japanese language processing and professional examinations.

However, no study has compared the performance of multiple LLMs on the Japanese Public Health Nurse National Examination, which assesses the knowledge and skills necessary

XSL•FO
RenderX

for public health nursing practice. The Public Health Nurse National Examination comprises content addressing community-based health issues, multidisciplinary collaboration, and public health nursing activities, requiring not only medical knowledge but also an understanding of Japan's community health systems [7]. Compared to clinical medicine, public health nursing presents unique challenges for LLMs. While medical examinations primarily assess biomedical knowledge and clinical reasoning, public health nursing requires the integration of social determinants of health, public health policy knowledge, community-level interventions, and understanding of local health systems. These multifaceted aspects demand complex reasoning that simultaneously considers multiple factors, which may pose greater challenges for current LLMs. Therefore, this study aimed to compare and evaluate the performance of GPT-4o (Open AI), Claude Opus 4 (Anthropic), and Gemini 2.5 Pro (Google AI) on questions from the Japanese Public Health Nurse National Examination to clarify the extent to which AI can respond to the specialized knowledge and skills necessary for public health nursing. We believe our work has significance for examining the potential for AI use in future public health nursing education.

Methods

Study Design

This comparative cross-sectional study evaluated the performance of 3 LLMs on the Japanese Public Health Nurse National Examination. We used a census sampling approach, analyzing all questions from the examination to compare accuracy rates across different LLMs and question types.

Tested LLMs

Three representative LLMs were selected: OpenAI's GPT-4o [1], Anthropic's Claude Opus 4 [2], and Google's Gemini 2.5 Pro [3].

Japanese Public Health Nurse National Examination

The Japanese Public Health Nurse National Examination is conducted based on the Act on Public Health Nurses, Midwives, and Nurses to assess the knowledge and skills necessary for public health nurses [8]. It includes 110 questions. The questions are classified as general and situational. General questions are worth 1 point each, whereas situational questions are worth 2 points each. The passing criterion is 60% correct answers for general and situational questions combined, although the percentage may be adjusted when inappropriate questions are excluded. The questions are in multiple-choice format, and the participants must select one or more correct answers from 4 to 5 options. The pass rate is 90% to 95%.

Study Population and Question Selection

This study used a census sampling approach, including all 110 questions from the 111th Public Health Nurse National Examination administered in February 2025 [9]. No sampling was conducted as the entire population of examination questions was analyzed. For questions containing figures and tables, figures were processed as image data, whereas the question text was handled as text. No questions were designated as inappropriate by the Ministry of Health, Labour and Welfare; the passing criterion was 60% [9]. The examination questions were classified according to format (text questions and figure or calculation questions), content (general and situational questions), and selection type (single- and multiple-choice questions).

Prompt Engineering

Because prompt engineering significantly affects the generated output, the question input formats were standardized. On the basis of previous research [4-6], 6 prompts corresponding to different types of questions were created (Table 1).

XSL•FO
RenderX

Table . Standardized prompts for different question types in the Japanese Public Health Nurse National Examination. Template placeholders ("<" and ">") indicate where specific content was inserted for each question type.

Prompt type	Prompt template
Prompt 1: general questions	"Japanese Public Health Nurse National Examination questions are presented. Please answer the following question in brief by selecting an option. Select one option unless otherwise specified. Question: <Question content> 1. <Option 1> 2. <Option 2> 3. <Option 3> 4. <Option 4> 5. <Option 5> (if applicable)"
Prompt 2: situational questions	"Japanese Public Health Nurse National Examination questions are presented. Based on the following situational setting, please answer the question in brief by selecting an option. Select one option unless otherwise specified. Situation: <Situational content> Question: <Question content> 1. <Option 1> 2. <Option 2> 3. <Option 3> 4. <Option 4> 5. <Option 5> (if applicable)"
Prompt 3: image questions	"Japanese Public Health Nurse National Examination questions are presented. Please review the following image and answer the question in brief by selecting an option. Select one option unless otherwise specified. Question: <Question content> 1. <Option 1> 2. <Option 2> 3. <Option 3> 4. <Option 4> 5. <Option 5> (if applicable)"
Prompt 4: situational questions with images	"Japanese Public Health Nurse National Examination questions are presented. Based on the following situational setting, please review the image and answer the question in brief by selecting an option. Select one option unless otherwise specified. Situation: <Situational content> Question: <Question content> 1. <Option 1> 2. <Option 2> 3. <Option 3> 4. <Option 4> 5. <Option 5> (if applicable)"
Prompt 5: calculation questions	"Japanese Public Health Nurse National Examination questions are presented. Please read the following question, review the mark sheet format in the image, and answer the question in brief by selecting an option. Provide your answer as a numerical value in brief. Question: <Question content>"
Prompt 6: situational calculation questions	"Japanese Public Health Nurse National Examination questions are presented. Please read the following situational setting and question, review the mark sheet format in the image, and answer the calculation question. Provide your answer as a numerical value in brief. Situation: <Situational content> Question: <Question content>"

Data Collection Procedures

Questions were input from June 25 to 26, 2025. The question text and images were directly inserted into each LLM's chat window. Each question was input in a new independent chat window to avoid potential influence from previous responses. All questions were administered in Japanese using standardized prompts.

The definition of "correct" answers was based on the official answers published by the Ministry of Health, Labour, and Welfare [9]. Only answers that clearly matched the official correct answers and followed the instructions provided in the question text were considered "correct." Ambiguous answers, evident mistakes, unclear responses, and responses with an excessive number of answer choices were considered incorrect. All responses from the LLMs were independently reviewed and scored by 2 authors (YT and RK), with any discrepancies resolved through discussion.

Data Analysis

For each LLM, the number of correct answers, accuracy rates, 95% CIs, total scores, and score rates were calculated. Accuracy rates were compared across question format (text vs figure or calculation), question content (general vs situational), and selection type (single vs multiple choice) both between LLMs (inter-LLM comparison) and within each LLM (intra-LLM comparison). Numerical input calculation questions were excluded from the selection type analysis.

Statistical comparisons were performed using chi-square tests for expected cell frequencies of ≥5 and the Fisher exact test when expected cell frequencies were <5. For multiple pairwise inter-LLM comparisons, the Bonferroni correction was applied to control for type I error. Statistical significance was set at $P \leq .05$ (2 tailed). All statistical analyses were conducted using Stata (version 18.0; StataCorp LLC).

Ethical Considerations

Ethics approval was not required because only data from a published database were analyzed.

Results

Detailed results are presented in Table 2. The accuracy rates for each LLM for all 110 questions were as follows: 85.5% (n=94) of the questions for GPT-4o (95% CI 77.5% - 91.5%), 91.8% (n=101) of the questions for Claude Opus 4 (95% CI 85.0% - 96.2%), and 92.7% (n=102) of the questions for Gemini 2.5 Pro (95% CI 86.2% - 96.8%). The corresponding scores

XSL•FO
RenderX

were 86.2% (125/145), 91.7% (133/145), and 93.1% (135/145), respectively, all of which exceeded the passing criterion (60%). In terms of question characteristics, the accuracy rates for general questions (n=75) were as follows: 84% (n=63) for GPT-4o, 92% (n=69) for Claude Opus 4, and 92% (n=69) for Gemini 2.5 Pro. The corresponding rates for situational questions (n=35) were 88.6% (n=31), 91.4% (n=32), and 94.3% (n=33), respectively.

Table . Performance of large language models (LLMs) on the 111th Public Health Nurse National Examination.

Category	GPT-4o		Claude Opus 4		Gemini 2.5 Pro		LLM comparison *P* value		
	Correct answers, n (%)	*P* value	Correct answers, n (%)	*P* value	Correct answers, n (%)	*P* value	GPT-4o vs Claude Opus 4	GPT-4o vs Gemini	Claude Opus 4 vs Gemini
Overall accuracy rate (n=110)	94 (85.5)	—[a]	101 (91.8)	—	102 (92.7)	—	>.99	>.99	>.99
Overall score (n=145)	125 (86.2)	—	133 (91.7)	—	135 (93.1)	—	>.99	>.99	>.99
By question content		.53		>.99		>.99			
General questions (n=75)	63 (84.0)		69 (92.0)		69 (92.0)		>.99	>.99	>.99
Situational questions (n=35)	31 (88.6)		32 (91.4)		33 (94.3)		>.99	>.99	>.99
By question format		.69		>.99		.60			
Text questions (n=98)	84 (85.7)		90 (91.8)		90 (91.8)		>.99	>.99	>.99
Figure or calculation questions (n=12)	10 (83.3)		11 (91.7)		12 (100.0)		>.99	>.99	>.99
By selection type		.04		.03		.09			
Single-choice questions (n=92)	82 (89.1)		87 (94.6)		87 (94.6)		>.99	>.99	>.99
Multiple-choice questions (n=16)	10 (62.5)		12 (75.0)		13 (81.3)		>.99	>.99	>.99

[a]Not applicable.

In terms of question format, the accuracy rates for the text questions (n=98) were as follows: 85.7% (n=84) for GPT-4o, 91.8% (n=90) for Claude Opus 4, and 91.8% (n=90) for Gemini 2.5 Pro. The corresponding rates for figure or calculation questions (n=12) were 83.3% (n=10), 91.7% (n=11), and 100% (n=12), respectively. The accuracy rates for single-choice questions (n=92) were as follows: 89.1% (n=82) for GPT-4o, 94.6% (n=87) for Claude Opus 4, and 94.6% (n=87) for Gemini 2.5 Pro. However, for the multiple-choice questions (n=16), all LLMs showed decreased accuracy, and the corresponding rates were 62.5% (n=10), 75% (n=12), and 81.3% (n=13), respectively.

Statistical comparisons among the LLMs showed no significant differences. Intra-LLM comparisons revealed significant differences between single- and multiple-choice questions for GPT-4o (*P*=.01) and Claude Opus 4 (*P*=.03), with the accuracy rates for multiple-choice questions being significantly lower.

Discussion

Principal Findings

This study compared and evaluated the performances of multiple LLMs on the Japanese Public Health Nurse National Examination. All the LLMs significantly exceeded the passing criterion of 60%. These results indicate that LLMs have acquired considerable specialized knowledge, with the performance of GPT-4o (94/110, 85.5%) being comparable to that of LLMs in previous medical examinations [4] and superior to that of older-generation models [6].

While all LLMs showed high overall accuracy rates, a clear performance decline was observed for multiple-choice questions. This contrasts with the high accuracy rates for single-choice questions, with significant differences found for GPT-4o and Gemini 2.5 Pro. This phenomenon demonstrates the current limitations of LLMs in complex reasoning, which requires the

XSL•FO
RenderX

simultaneous evaluation of multiple concepts. As public health nursing practice requires comprehensive judgment considering multiple factors such as regional characteristics, residents' needs, social resources, and multidisciplinary collaboration, the performance decline on multiple-choice questions indicates that LLMs have limitations in the complex decision-making faced in actual public health nursing practice.

The accuracy rates of the LLMs evaluated in this study (94/110, 85.5% to 102/110, 92.7%) and their scores (125/145, 86.2% to 135/145, 93.1%) substantially exceeded the passing standard (60%). The pass rate for the 111th Public Health Nurse National Examination was 94% [9]; however, this represents the proportion of examinees who exceeded the passing standard, and the overall mean score for all examinees is not publicly available. Therefore, a direct comparison between the overall academic performance of examinees and LLM performance is challenging.

In the field of medical education, multiple studies comparing LLM and student performance have been reported. A study comparing final-year emergency medicine students with AI models [10] demonstrated that students achieved a 79.4% accuracy rate, outperforming ChatGPT (72.5%) and Gemini (54.4%). The superiority of students was particularly pronounced in image-based questions, highlighting current limitations in AI models' visual information processing capabilities. Additionally, a study using 1070 medical imaging questions [11] found that GPT-4 correctly answered 67.8% of the questions it attempted, whereas the students' passing mean was 63%. However, the student majority vote achieved a 94.5% accuracy rate, substantially surpassing the AI. This demonstrates that even when individual students' abilities may be equal to or slightly inferior to those of AI, collective student judgment significantly exceeds AI performance.

In our study, while LLM performance on figure or calculation questions was high (10/12, 83.3% to 12/12, 100%), the small number of questions (n=12) necessitates larger-scale validation. More importantly, the learning processes of LLMs and humans are fundamentally different. LLMs learn patterns from large volumes of text data, whereas public health nurses acquire decision-making capabilities by integrating practical experience with theoretical knowledge. Furthermore, human public health nurses possess essential practical competencies that are not measurable through written examinations, including ethical judgment, empathy, and interpersonal communication skills. As these previous studies [10,11] demonstrate, while AI shows potential as a supplementary educational tool, it cannot replace human capabilities, particularly in areas requiring visual interpretation, clinical reasoning, and collective judgment. Therefore, LLMs should be appropriately positioned as educational and learning support tools rather than as replacements for human public health nurses.

The results of this study have important implications from the perspective of competency development in public health nursing education. The "Practical Competencies Required of Public Health Nurses and Achievement Goals and Levels at Graduation" document by the Japanese Ministry of Health, Labour and Welfare [12] classifies public health nurse competencies into five domains: (1) ability to clarify community health issues and develop plans; (2) ability to provide continuous support and collaborative organizational activities for individuals, families, groups, and organizations to enhance community health promotion capacity and evaluate these activities; (3) community health crisis management capacity; (4) ability to develop projects, policies, social resources, and systems to enhance community health levels; and (5) professional autonomy and continuous quality improvement capacity. LLMs may be particularly effective in providing learning support during information gathering and assessment stages within domain 1. This competency includes information collection for clarifying community health issues, community diagnosis, and prioritization of health issues, where LLMs are expected to play a supplementary role in confirming foundational knowledge and organizing information.

For domain 1, the achievement level at graduation is set at either level 1 ("able to implement independently with minimal guidance") or level 2 ("able to implement under supervision [from supervising public health nurses or faculty]") [12]. As revealed in this study, LLMs demonstrated a performance decline in multiple-choice questions and have limitations in complex judgment tasks. Therefore, when using LLMs as educational tools, it is crucial to cultivate students' ability to critically evaluate LLM outputs and maintain practical judgment skills based on community characteristics to reach these achievement levels.

Several ethical considerations must be addressed when using LLMs in public health nursing education. The Japanese Ministry of Education, Culture, Sports, Science and Technology guidelines [13] indicate that directly using generative AI outputs does not deepen students' own learning, that differences in generative AI types (paid vs free versions) may create disparities in student outcomes leading to unfairness, and that confidential and personal information may be unintentionally leaked or disclosed. A survey of Japanese medical students [14] found that while 41.9% had experience using ChatGPT, only 10.2% had used it for medical assignments and 47% held negative views about its use for medical reports. Many students felt that, considering the time required to verify AI responses, independent learning would be more efficient, highlighting the essential need to cultivate critical evaluation skills for LLM outputs. A narrative review on chatbot integration in nursing education [15] also emphasizes the importance of ethical considerations, indicating the urgent need to establish ethical frameworks for AI use across nursing education.

The results of this study revealed that while LLMs demonstrated high accuracy rates on the Public Health Nurse National Examination, performance declined on multiple-choice questions. This finding has important implications for using LLMs as learning support tools in public health nursing education. Given the demonstrated limitations of LLMs in complex judgment requiring simultaneous consideration of multiple factors, LLMs are suitable for supplementary roles such as confirming foundational knowledge and gathering information, whereas faculty instruction remains crucial for learning scenarios requiring complex judgment. The Ministry of Education, Culture, Sports, Science and Technology has

XSL•FO
RenderX

issued guidelines [13] on the educational use of generative AI at universities and colleges of technology, and public health nurse training institutions are also called upon to develop guidelines that clearly specify appropriate use scenarios and limitations for LLMs. A nationwide survey on information and communications technology (ICT) use among public health nurses in local governments [16] found that 82.8% responded that they did not know the procedures for promoting ICT use, indicating challenges in adapting to digital technology even among practicing public health nurses. This suggests the importance of providing systematic digital literacy education from the public health nurse training stage.

A detailed examination is needed regarding curriculum integration and faculty training. For example, development of specific implementation strategies is required, including in which courses and how LLMs should be introduced, how to design a phased introduction process, and how faculty should learn appropriate LLM use methods. In particular, establishing organizational training systems for enhancing faculty AI literacy and developing assessment methods premised on LLM use are important future challenges. To accumulate knowledge regarding these strategies, pilot program implementation and evaluation will be necessary.

As practical implications, there is potential for the use of LLMs as continuing education and self-directed learning support tools for practicing public health nurses. A concept analysis of LLMs in nursing education [17] positions LLMs as transformative tools that provide accessible and personalized learning support and promote cognitive and skill development. In public health nursing education as well, use is anticipated for responding to new public health issues and during information gathering stages in community diagnosis. Additionally, there is potential for the use of LLMs as an auxiliary tool in situations requiring rapid information organization, such as during disasters or emerging infectious disease outbreaks. However, a survey on ICT use among public health nurses in local governments [16] found that 89.1% of municipalities expressed concerns about individuals who have difficulty adapting to digital technology, necessitating careful introduction that considers the essence of interpersonal support in public health nursing work. Furthermore, while 55.9% in the same survey actively promoted ICT use, only 26.7% perceived progress as smooth, indicating challenges in digital literacy education for practicing public health nurses and establishing organizational support systems. As noted in the aforementioned concept analysis [17], careful attention must be paid to LLM limitations and ethical implications, ensuring that LLM integration aligns with the values and goals of nursing education. Therefore, when using LLMs in practical settings, it is essential to critically evaluate LLM outputs and integrate them with community characteristics and practical knowledge, considering the limitations in complex judgment revealed in this study.

The findings of this study occupy an important position within the broader context of AI use in health profession education. A narrative review on chatbots in nursing education [15] demonstrated a surge in related research from 2021 to 2023 (with 2023 accounting for 70% of publications), indicating growing scholarly interest in this field. Together with LLM evaluation studies on medical licensing examinations [4,5], it is becoming increasingly clear that LLMs demonstrate high performance across medical licensing examinations generally. However, the performance decline on multiple-choice questions demonstrated in this study indicates the existence of LLM limitations in complex judgment unique to public health nursing, such as integration of social determinants of health and planning of community-level interventions. This is consistent with findings from previous studies in medical education [10,11] showing that collective student judgment far exceeds that of AI, supporting the appropriate positioning of LLMs as educational and learning support tools rather than replacements for human health professionals. Additionally, a survey of medical students [14] showed that 47% held negative views about LLM use for medical assignments, indicating the recognition of the need for verification. A concept analysis in nursing education [17] also pointed out the need for careful consideration of LLM limitations and ethical implications. Furthermore, the aforementioned review on chatbot integration in nursing education [15] emphasizes the importance of ethical considerations and the urgency of original research while acknowledging it as a promising field. Collectively, these findings suggest that across health profession education generally, while LLMs have potential as useful auxiliary tools, cultivating the ability to understand their limitations and use them critically is a common challenge across all types of health profession education.

Limitations and Future Directions

This study has the following strengths. First, this is the first study to evaluate the performance of multiple LLMs on the Public Health Nurse National Examination. While LLM evaluations have been conducted on medical and nursing licensing examinations, this study represents the first systematic evaluation in the public health nursing field. Second, reproducibility was ensured through the use of standardized prompts. Six prompts were created according to question types, achieving consistent evaluation. Third, detailed analysis by question format revealed the important finding of performance decline on multiple-choice questions. This discovery demonstrates LLM limitations in complex reasoning requiring the simultaneous consideration of multiple factors, with important implications for future educational implementation.

This study has several limitations. First, as a cross-sectional evaluation of a single year, temporal changes in LLM performance and reproducibility across different examination years could not be evaluated in this study. Second, accuracy rates alone do not clarify the quality of reasoning processes or correlation with actual public health nursing practice competencies. Third, while LLM versions and settings may influence results, this study was limited to evaluation using specific versions (GPT-4o, Claude Opus 4, and Gemini 2.5 Pro). Fourth, results may vary depending on prompt expression methods, and there is no guarantee that the standardized prompts used in this study are optimal. Fifth, because the overall mean score for examinees is not publicly available, direct performance comparison between LLMs and human public health nurse examinees is difficult. Furthermore, this study verified LLM performance in the educational evaluation context of a national

XSL•FO
RenderX

examination and did not evaluate their utility or safety as decision support tools in actual public health nursing practice. Future research should include continued evaluation over multiple years, qualitative analysis of reasoning processes, validation of utility in practical settings, comparative studies with human public health nurses, and examination of applicability to decision support in actual practice.

Conclusions

The LLMs evaluated demonstrated high performance on the Public Health Nurse National Examination; however, they also had limitations in solving problems requiring complex judgment. These findings provide important foundational data showing the possibilities and challenges of AI use in public health nursing. On the basis of these results, LLMs should be cautiously used as supplementary tools in public health nursing education.

Abstract

Background: Clinical AI decision support is being introduced into nursing practice; however, existing large language models (LLMs) demonstrate only moderate accuracy on complex clinical tasks, raising questions about the level of accuracy required for safe clinical use across varying levels of clinician experience and task complexity.

Objective: The aim of the study is to develop an empirically calibrated simulation model of human-AI reliance and error in nursing decision-making and estimate the AI accuracy required to achieve specified error rate targets.

Methods: A linear reliance model with coefficients for AI accuracy (A), clinician experience (E), and task complexity (C) was calibrated using weighted least squares against 9 empirical data points from 3 independent randomized experiments on AI-assisted decision-making (N=3502). Predicted error was computed as reliance×(1−*A*) across a 27-cell factorial design. Study-level bootstrap (2000 iterations) quantified calibration uncertainty. To contextualize the simulation's operating range, the accuracy of contemporary general-purpose LLMs on complex clinical tasks was drawn from published benchmarks.

Results: Calibration placed β_A at 0.201 (bootstrap 95% CI 0.023 - 0.234; $P(\beta_A>0)>.99$). For the novice×high-complexity combination, the minimum AI accuracy values required to achieve error rates <10% and<20% were 0.89 and 0.78, respectively (bootstrap 95% CIs 0.88 - 0.90 and 0.75 - 0.79). At the moderate accuracy levels currently reported for general-purpose LLMs on complex clinical tasks (approximately 0.5 - 0.7), the model predicts error rates of roughly 26% to 41% in this high-risk condition.

Conclusions: In this model, keeping predicted error rates below a stringent target (<10%) for high-complexity nursing decision support by novice clinicians requires AI accuracy of at least approximately 0.89, a level that current general-purpose LLMs may not reliably reach on complex clinical tasks. Because the model is calibrated on nonnursing reliance data, these thresholds are illustrative model outputs, not nursing-derived empirical standards. The $A_{threshold}$ framework provides a decision-theoretic tool for evaluating the minimum AI accuracy requirement by user-and-task profile. Behavioral validation in nursing contexts remains an essential next step. Because the framework is independent of any specific model, it remains applicable as AI systems improve.

clinical decision support; automation bias; large language models; nursing informatics; Monte Carlo simulation; error threshold

Introduction

The integration of AI, particularly large language models (LLMs), into nursing education and clinical practice has increased substantially in recent years [1-4]. Although these systems present considerable opportunities to augment clinical reasoning and decision-making, they simultaneously introduce novel risks associated with human reliance on AI-generated outputs [5]. A critical concern is how accurate current AI systems must be for safe use in clinical tasks, particularly because clinical decision support systems can improve care but also introduce safety risks when their outputs are relied upon uncritically [6-8].

Research in human factors and automation science has long demonstrated that users often develop inappropriate levels of trust in automated systems, resulting in overreliance and consequent errors [9,10]. Parasuraman and Riley [9] identified "misuse"—overreliance on automation that produces failures in monitoring or detecting system errors, as a principal failure mode of human-automation interaction. Lee and See [10] subsequently articulated a framework of appropriate reliance in which trust should be calibrated to a system's demonstrated capabilities. In health care specifically, systematic reviews have documented automation bias as a recurring safety concern in computerized clinical decision support, identifying task complexity, cognitive load, and verification demands as

XSL•FO
RenderX

principal mediators of overreliance [11-13]. Despite the established relevance of these frameworks, their quantitative application to health care AI, and to nursing in particular, remains largely underexplored.

Recent empirical studies have begun to characterize human-AI reliance relationships in AI-assisted decision-making. Yin et al [14] conducted 3 preregistered randomized experiments (total n=3793) and reported that participants relied more on AI systems, as the systems' stated and observed accuracy increased, with agreement fractions rising from approximately 0.75 at 60% accuracy to 0.82 at 95% accuracy in their first experiment. Lu and Yin [15] reported a similar monotonic trend in a subsequent study (n=466, 13,980 trials). In clinical settings, Kücking et al [16] demonstrated that AI recommendation correctness exerted a strong bidirectional influence on the diagnostic accuracy of 223 physicians and nurses assessing wound maceration; correct AI recommendations increased the odds of correct decisions approximately 10-fold (odds ratio [OR] 10.0; P<.001), whereas incorrect recommendations significantly reduced accuracy. These findings indicate that automation complacency concerns extend to contemporary AI-based clinical decision support systems and motivate a theoretically grounded, quantitative investigation of the conditions under which AI-assisted clinical errors are most likely to occur.

However, a critical gap remains between the available empirical literature and clinical use decisions. Current studies characterize human-AI reliance in qualitative terms or across a limited range of accuracy levels; yet, they do not provide clinicians or administrators with a decision-theoretic tool for determining whether an AI system, given its measured accuracy, is appropriate for a specific clinical task and user group. Such a tool is increasingly needed because, although LLMs achieve high scores on standardized medical knowledge benchmarks [17], their accuracy on more complex, open-ended clinical decision-making tasks remains only moderate [18,19], placing current systems within an operating range where the clinical safety implications are neither self-evident nor reliably inferable from the raw accuracy value alone.

To address this gap, this study developed a linear simulation model of human-AI reliance in nursing decision-making, empirically calibrated against 9 data points derived from 3 independent randomized experiments on AI-assisted decision-making (total N=3502). Error rates were computed as the product of predicted reliance and AI failure probability and evaluated across a 27-cell factorial design spanning 3 AI accuracy levels, 3 clinician experience levels, and 3 task complexity levels. This work has two primary contributions: (1) empirical calibration of the reliance model from 3 independent large-scale datasets, which avoids the circularity inherent in purely theoretical parameter selection; and (2) introduction of $A_{threshold}$, a decision-theoretic parameter that quantifies the minimum AI accuracy required to achieve a specified clinical error rate target for a specific user-and-task profile.

Clinical AI decision support is being introduced into nursing practice without quantitative guidance on the minimum AI accuracy required for safe use. The $A_{threshold}$ framework presented here is expected to benefit nursing educators, clinical informaticists, hospital administrators evaluating AI deployment, and regulators developing accuracy standards for clinical AI decision support systems. This work is submitted to the JMIR Nursing theme issue on Artificial Intelligence (AI) in Nursing, addressing the in-scope topics of LLM use in settings where nurses provide care, comparisons of AI algorithm effectiveness in supporting decision-making among nurses, and strengths and limitations of AI technologies in nursing practice.

Methods

Study Design

This study used a theoretical Monte Carlo simulation calibrated against published human-AI reliance data. The published human data were used to calibrate the model's accuracy-related parameters, while all other parameters not determined by calibration were specified a priori from theoretical considerations and tested through sensitivity analysis. To ensure that the simulation's operating range was ecologically plausible, the accuracy of contemporary general-purpose LLMs on complex clinical tasks was characterized using published benchmarks [18,19] rather than a separate in-house evaluation.

Ethical Considerations

This study did not involve human participants or the use of patient data; it comprised a computational simulation calibrated against previously published, publicly available aggregate data. Accordingly, institutional review board approval was not required.

Theoretical Framework and Model Formulation

Reliance Model

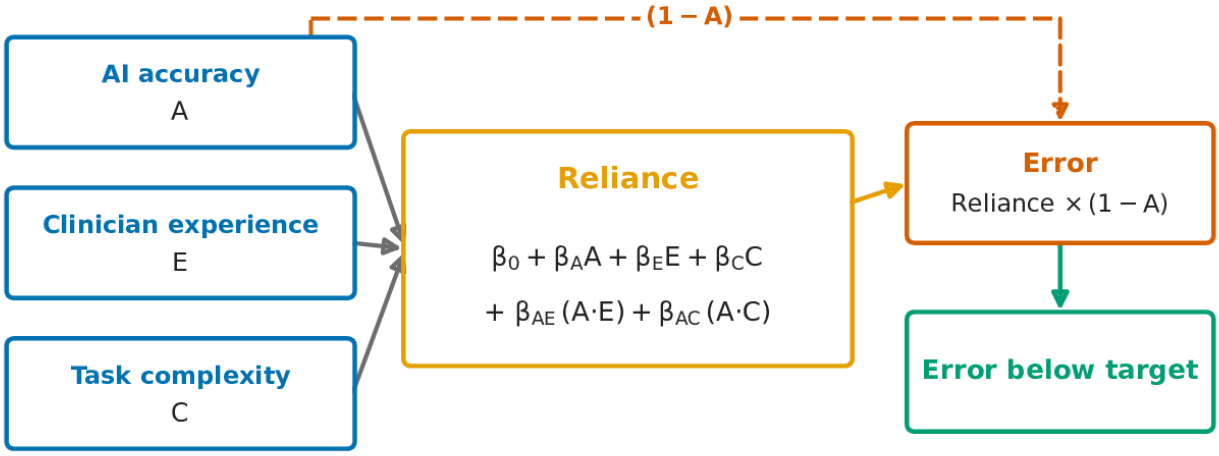
Human reliance on AI was modeled as a linear function of AI accuracy, clinician experience, and task complexity:

$$\text{Reliance}=\beta+\beta_A\cdot A+\beta_E\cdot E+\beta_C\cdot C+\beta_{AE}\cdot(A\times E)+\beta_{AC}\cdot(A\times C)+\varepsilon_1 \quad (1)$$

where A denotes AI accuracy on [0, 1]; E signifies clinical experience normalized by dividing the years of experience by 10 (so that 0, 2, and 10 years map to 0.0, 0.2, and 1.0, respectively); C represents task complexity coded as 0.0 (low), 0.5 (moderate), and 1.0 (high); and $\varepsilon_1 \sim N(0, \sigma=0.05)$. To preserve its probabilistic interpretation, reliance was clipped to the interval [0, 1].

The linear form was chosen over more elaborate specifications (eg, a logistic trust mediator with a quadratic accuracy penalty) for 3 reasons. First, it is parsimonious, as it contains the minimum parameters needed to capture additive effects of accuracy, experience, and complexity with their 2-way interactions. Second, it can be directly calibrated against published reliance data using standard regression methods, whereas more elaborate specifications add extra parameters that cannot be reliably estimated from the available data. Third, empirical studies of human-AI reliance consistently reported approximately linear relationships between AI accuracy and reliance across the 0.5 - 1.0 range [14,15], which empirically justifies the linear specification.

XSL•FO
RenderX



Error Model

Error was modeled as the product of behavioral reliance and the AI failure rate with additive Gaussian noise:

$$\text{Error} = \text{reliance} \times (1 - A) + \varepsilon_2 \quad (2)$$

where $\varepsilon_2 \sim N(0, \sigma = 0.02)$, with error subsequently clipped to [0, 1]. This specification assumes that an erroneous AI recommendation leads to a clinical error only to the extent that the clinician relies on it. Figure 1 presents the conceptual model of human-AI interaction in nursing decision-making.

Figure 1. Conceptual model of AI-assisted clinical decision-making. Inputs (AI accuracy A, clinician experience E, and task complexity C) feed the reliance equation with additive main effects and 2-way interactions ($A \times E$ and $A \times C$). The accuracy-related coefficients β and β_A were empirically calibrated against 9 data points drawn from 3 independent randomized experiments on AI-assisted decision-making (total N=3502). The remaining coefficients were fixed from prior theoretical considerations. Error is computed as reliance×(1−*A*), so AI accuracy enters the error term both indirectly through reliance and directly through the (1−*A*) factor. The predicted error is then compared against a specified target error rate. β_0 and β_A were calibrated from 9 empirical reliance points [14,15]; β_E, β_C, β_{AE}, and β_{AC} were fixed from the literature.

Model Calibration

The *A*-related coefficients of the reliance model (β and β_A) were calibrated using weighted least squares against 9 empirical data points derived from 3 independent randomized experiments on AI-assisted decision-making. Studies met 3 prespecified criteria: experimental manipulation of AI accuracy at ≥2 levels in the 0.5 - 1.0 range, reported behavioral measure of reliance (agreement fraction, switch fraction, or equivalent), and total study n≥100.

In total, 3 studies met all 3 criteria. In all 3 experiments, laypeople recruited via Amazon Mechanical Turk used a machine-learning classifier to predict the outcomes of speed-dating events (whether a given participant would want to meet their date again), and reliance was operationalized as the agreement (or switch) fraction between the participant's final decision and the model's prediction. Lu and Yin [15] (experiment 2; n=466 crowdworkers; 13,980 trials) manipulated the designed AI accuracy (50% and 80%) and measured the final agreement rate. Individual-level data were obtained from authors' publicly available dataset [20] and reanalyzed to obtain worker-level reliance means at each accuracy level (*A*=0.50: n=252; mean 0.642, SD 0.139; *A*=0.80: n=214; mean 0.664, SD 0.134). Yin et al [14] (experiment 1, phase 1; n=1994; stated accuracy ∈ {60%, 70%, 90%, 95%}; agreement fraction with observed accuracy of 80% and experiment 3, phase 2; n=1042; observed accuracy ∈ {55%, 80%, 100%}; agreement fraction averaged across 2 stated accuracy levels) contributed 4 and 3 data points, respectively. Values were extracted from the published figures (Figures 3a and 5a) of Yin et al [14] by visual inspection. The 2 Yin et al [14] experiments used here (experiment 1, phase 1 and experiment 3, phase 2) together comprised 3036 of the 3793 participants reported across that study's 3 experiments; adding the 466 crowdworkers of Lu and Yin [15] yields the total calibration sample of 3502. Experiments and phases that did not manipulate AI accuracy across at least 2 levels in the 0.5 - 1.0 range were not used for calibration.

All calibration targets correspond to the clinician-experience value *E*=0 (laypeople crowdworkers) and the task complexity value *C*=0.5 (moderate complexity; speed-dating outcome prediction requires the integration of multifeature personal profiles). Calibration was performed by minimizing the sum of the squared residuals weighted by the square root of each study's sample size using the Nelder-Mead simplex algorithm in SciPy (version 1.13; NumFOCUS). The other coefficients (β_E, β_C, β_{AE}, and β_{AC}) were set from prior theoretical considerations and are described in the Parameter Specification section.

Calibration yielded β=0.471 (baseline reliance at *A*=0, *E*=0, *C*=0.5 with literature-fixed complexity contribution) and β_A=0.201 (reliance increase per unit of AI accuracy). The calibrated model achieved a root-mean-square error (RMSE) of 0.054 across the 9 empirical points.

To evaluate the precision of the calibrated coefficients given the limited number of independent data sources, study-level bootstrap resampling was run with 2000 iterations. For each iteration, the 3 studies were sampled with replacement, and β and β_A were recalibrated on the resulting target set. Leave-one-study-out cross-validation was also conducted by

XSL•FO
RenderX

excluding each study in turn and recalibrating the remaining 2. The bootstrap distribution and leave-one-out results are presented in the Results section.

Parameter Specification

The remaining 4 coefficients were specified a priori based on theoretical considerations and were not estimated from the calibration data. The coefficient for clinical experience in the reliance equation (β_E=−0.20) reflects two complementary mechanisms: (1) expertise development cultivates reliance on internalized clinical knowledge and pattern recognition rather than on external decision aids [21,22] and (2) empirical studies in clinical AI decision support have shown that longer work experience is directly associated with reduced susceptibility to incorrect AI recommendations (OR 1.89 for work experience in a recent study of 223 health care professionals [16]). The coefficient for task complexity (β_C=+0.20) operationalizes evidence that increased cognitive load is associated with reliance on decision aids [9]. The 2 interaction coefficients (β_{AE}=+0.10 and β_{AC}=+0.10) represent, respectively, expertise-based attenuation and complexity-based amplification of accuracy effects. These values are theoretically motivated rather than empirically estimated. The specific magnitudes (|β|=0.10 - 0.20) were chosen as conservative nominal values, deliberately set at or below the magnitude of the calibrated accuracy slope ($|\beta_A|$≈0.20) so that these unvalidated assumptions would not dominate the empirically calibrated reliance-accuracy relationship; they are not presented as precise estimates. Because 9 aggregate calibration points cannot identify these 4 coefficients empirically, alternative specifications were not selected on the basis of statistical fit; instead, the influence of these values was bounded through the sensitivity analyses described below, which span a plausible range of alternative magnitudes.

Simulation Conditions

In a Monte Carlo simulation, an outcome of interest is estimated by repeatedly drawing random values from specified probability distributions and averaging the results across many simulated trials; here, this approach propagated the small random variation in the modeled reliance and error terms into stable estimates of the mean predicted error rate for each condition. A full factorial design was used: 3 levels of AI accuracy (0.5, 0.7, and 0.9)×3 levels of clinical experience (0, 2, and 10 years)×3 levels of task complexity (low, moderate, and high)=27 conditions. Each condition was simulated with 10,000 Monte Carlo trials (total n=270,000 simulated decision trials). The pseudorandom number generator was initialized with seed 42 using the numpy default_rng interface for full reproducibility.

$A_{threshold}$ Analysis

The minimum AI accuracy required to achieve a specified clinical error rate target (denoted as $A_{threshold}$) was computed analytically for each combination of clinical experience and task complexity. Given the linear reliance specification, the predicted mean error is a quadratic function of A:

$$\text{Error}(A|E, C)=[(\beta+\beta_E\cdot E+\beta_C\cdot C)+(\beta_A+\beta_{AE}\cdot E+\beta_{AC}\cdot C)\cdot A]\times(1-A) \quad (3)$$

For a specific target error threshold T, $A_{threshold}$ was computed as the smallest $A \in [0, 1]$ at which error($A|E, C$)≤T, obtained through a dense grid search over 1000 values of A. In total, 4 target error thresholds were evaluated, namely, 5%, 10%, 15%, and 20%. These values were not adopted from a single validated benchmark; rather, they constitute a graded series of progressively stricter error rate targets intended to span the range of error tolerances plausibly relevant to clinical decision support, from comparatively lenient targets appropriate to low-stakes supportive use to stringent targets appropriate to higher-stakes settings. Consistent with the exploratory aim of this study, the resulting $A_{threshold}$ values should be interpreted as normative, hypothesis-generating estimates rather than as empirically validated error rate targets, and the specific threshold relevant to any given deployment will depend on the clinical context.

Sensitivity Analysis

To assess model robustness, each literature-fixed coefficient (β_E, β_C, β_{AE}, and β_{AC}) was systematically perturbed by ±20% from its baseline value. The calibrated coefficients (β and β_A) were not perturbed because they were empirically determined rather than theoretically assumed. For each variant, the entire 27-cell simulation was rerun, and the resulting cell-level error rates were compared with baseline using Spearman rank correlation and maximum absolute error difference.

Joint Human-AI Decision Model

The primary error specification (error=reliance×(1−A)) attributes a clinical error solely to reliance on an incorrect AI recommendation and therefore represents the limiting case, in which the clinician contributes no independent accuracy. Human-AI teams do not always outperform either party alone and can even perform worse on decision-making tasks [23,24]—for example, a randomized trial found that giving physicians access to an LLM did not significantly improve their diagnostic reasoning over conventional resources [25]. In addition, users frequently overrely on AI by following incorrect recommendations [13], and appropriate reliance requires accepting correct advice while rejecting incorrect advice [26]. For these reasons, a joint human-AI decision model was additionally analyzed that represents both outcomes of an AI-assisted decision explicitly: when the clinician follows the AI, an error occurs if the AI is incorrect; and when the clinician overrides the AI, an error occurs if the clinician's own independent judgment is incorrect. Writing R for reliance (the probability of following the AI), A for AI accuracy, and p_c for the clinician's independent accuracy, the expected team error is $\text{error}_{joint}=R\times(1-A)+(1-R)\times(1-p_c)$. The primary model is recovered exactly as the special case $p_c\to1$ (a clinician who is always correct when acting independently); this was verified to reproduce the reported $A_{threshold}$ values (0.894 and 0.779 for the novice×high-complexity cell at the <10% and <20% targets). An asymmetric variant additionally distinguished passive deference to an incorrect recommendation from active correction of one by scaling the corrective term by a factor ρ ∈ [0, 1], where ρ=1 recovers the symmetric model, and smaller ρ represents clinicians who more often catch and overturn a wrong

XSL•FO
RenderX

recommendation. $A_{threshold}$ was recomputed under this model across clinician-accuracy levels $p_c \in \{0.6, 0.7, 0.8, 0.9, 1.0\}$.

Extended Sensitivity Analysis

To probe robustness beyond the ±20% perturbations, 3 additional analyses were performed. First, each literature-fixed coefficient was varied over a wide one-at-a-time range (−100%, −50%, +50%, and +100% of its baseline magnitude, together with a full sign reversal), and the 27-cell simulation was rerun for each variant. Second, a global Monte Carlo analysis simultaneously sampled all 4 literature-fixed coefficients from prior distributions across 50,000 draws under 2 priors: a theory-signed prior that preserved the assumed direction of each coefficient while allowing its magnitude to vary widely, and a fully sign-agnostic prior that additionally permitted every assumed sign to reverse. The resulting distribution of $A_{threshold}$ values for the highest-risk (novice×high-complexity) and lowest-deference (experienced×low-complexity) cells was summarized by its median, 5th- to 95th-percentile interval, and the probability of exceeding an accuracy of 0.70. Third, to test whether the conclusions were an artifact of the linear reliance form, 2 bounded alternative structures—a logistic (sigmoid) reliance function and a concave saturating function—were fit to the same 9 calibration points, and $A_{threshold}$ was recomputed from each. These analyses are reported in the Results section, summarized in Multimedia Appendix 1, and provided in full in the repository.

Results

Model Calibration

Weighted least-squares calibration of the reliance model against the 9 empirical data points yielded $\beta = 0.471$ and $\beta_A = 0.201$. The calibrated model achieved an RMSE of 0.054 across the calibration targets (unweighted $R^2 = 0.34$, reflecting between-study heterogeneity in baseline reliance that the model does not attempt to capture). Multimedia Appendix 2 overlays the calibrated model predictions on the 9 empirical data points, stratified by the source study.

Study-level bootstrap resampling (2000 iterations) yielded a 95% CI for β_A of 0.023 - 0.234, which reflects the small number of independent calibration sources and the between-study heterogeneity in baseline reliance. Despite this width, the sign of β_A was stable across all 2000 bootstrap iterations ($P(\beta_A > 0) > .99$), confirming that the monotonic positive relationship between AI accuracy and reliance is empirically robust. The leave-one-study-out cross-validation produced recalibrated β_A values of 0.094 (excluding Lu and Yin [15]), 0.246 (excluding experiment 3 by Yin et al [14]), and 0.199 (excluding experiment 1 phase 1 by Yin et al [14]). This finding indicates that the calibration depends most heavily on the study by Lu and Yin [15] but does not collapse upon its removal. Per-study calibration yielded β_A estimates of 0.023, 0.037, and 0.158, all positive: the joint calibration value of 0.201 represents the precision-weighted aggregate across these heterogeneous study-level estimates.

Two features of the calibration result warrant emphasis. First, the calibrated slope ($\beta_A = 0.201$) indicates that each 0.10-unit increase in AI accuracy corresponds to approximately a 0.02-unit increase in the predicted mean reliance. This is considerably weaker than the reliance-accuracy relationships assumed in some theoretically motivated frameworks and reflects the fact that human reliance on AI systems is sensitive to, but not dominated by, the accuracy of the system. Second, the 3 studies contributing calibration data have different baseline reliance levels (Lu and Yin [15]: mean≈0.65; experiment 1 by Yin et al [14]: mean≈0.78; and experiment 3 by Yin et al [14]: mean≈0.82), a heterogeneity that the linear model averages across rather than resolves. Residuals were accordingly approximately symmetric around 0, but the RMSE was markedly larger than the SEs of the study means, an outcome we interpret as reflecting unmodeled study-level factors rather than misspecification of the functional form in the accuracy dimension.

Predicted Reliance and Error Rates

Table 1 presents the predicted error rates across all 27 simulation conditions. The underlying predicted reliance values ranged from 0.421 (experienced clinicians on low-complexity tasks with $A = 0.5$) to 0.938 (novice clinicians on high-complexity tasks with $A = 0.9$), reflecting the combined influence of accuracy, experience, and complexity on the tendency to accept AI recommendations. Notably, the calibrated slope on A is sufficient to produce an approximately 0.08-unit increase in mean reliance between $A = 0.5$ and $A = 0.9$, but insufficient to generate an interior maximum of predicted error rate as a function of A.

XSL•FO
RenderX

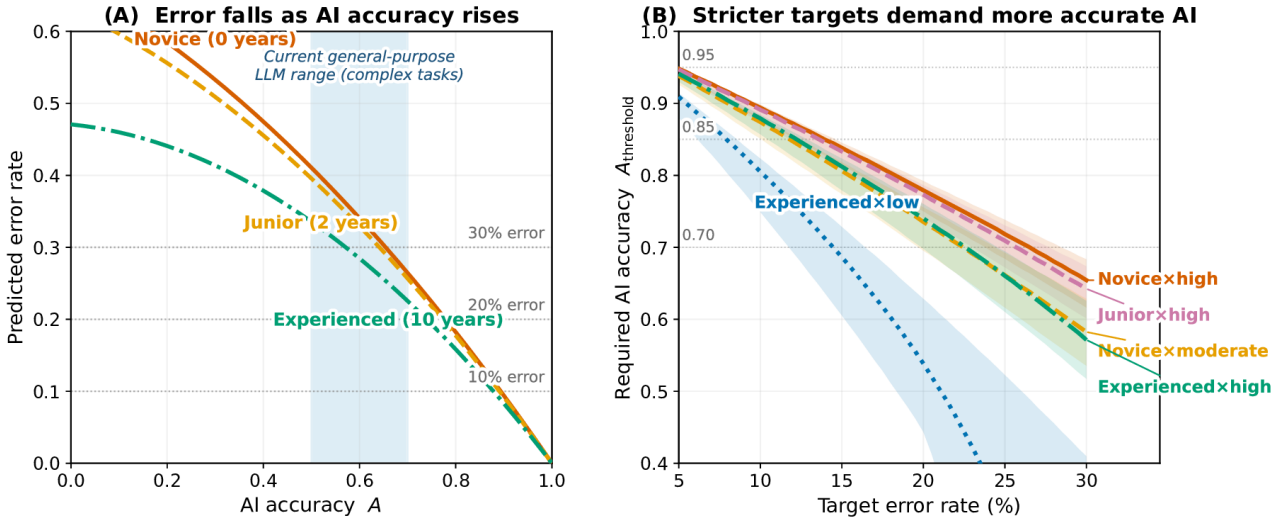


Table . Predicted error rates by simulation condition[a].

AI accuracy	Experience (years)	Low complexity, mean (SD)	Moderate complexity, mean (SD)	High complexity, mean (SD)
0.5	0	0.29 (0.03)	0.35 (0.03)	0.41 (0.03)
0.5	2	0.27 (0.03)	0.33 (0.03)	0.40 (0.03)
0.5	10	0.21 (0.03)	0.27 (0.03)	0.34 (0.03)
0.7	0	0.18 (0.03)	0.22 (0.03)	0.26 (0.03)
0.7	2	0.18 (0.03)	0.22 (0.03)	0.26 (0.03)
0.7	10	0.14 (0.03)	0.19 (0.03)	0.23 (0.03)
0.9	0	0.07 (0.02)	0.08 (0.02)	0.09 (0.02)
0.9	2	0.06 (0.02)	0.08 (0.02)	0.09 (0.02)
0.9	10	0.05 (0.02)	0.07 (0.02)	0.08 (0.02)

[a]Values are mean (SD) of simulated error rates across 10,000 Monte Carlo trials per cell (seed=42).

The predicted error rates exhibited a clean 3-tier structure when grouped by AI accuracy level. At A=0.9, all 9 cells fell below a 10% error rate (range 0.054 - 0.094). At A=0.7, the predicted error rates ranged from 0.145 to 0.265, spanning the 10% - 20% and 20% - 30% ranges, with all 3 novice cells exceeding 18% predicted error. At A=0.5, the predicted error rates ranged from 0.211 to 0.411, with all 6 moderate- and high-complexity cells exceeding 27% predicted error. For the cell most representative of the clinically high-risk scenario (novice clinicians performing high-complexity tasks), the predicted error rates were 0.411 at A=0.5, 0.265 at A=0.7, and 0.094 at A=0.9 (Figure 2A).

Figure 2. Predicted error rates and accuracy thresholds for AI decision support in nursing. (A) Predicted mean error rate as a function of AI accuracy A at high task complexity (C=1.0) for 3 experience levels. The horizontal dotted lines mark 10%, 20%, and 30% target error rates. The shaded vertical band marks a reference range for the accuracy of contemporary general-purpose LLMs on complex clinical tasks (approximately 0.5 - 0.7), based on published benchmarks [18,19]. (B) $A_{threshold}$ curves plotting the required AI accuracy against the target error-rate threshold for 5 representative experience-by-complexity combinations. Solid and dashed lines show point estimates from the calibrated model. The shaded bands represent study-level bootstrap 95% CIs (2000 iterations). Horizontal reference lines mark a reference LLM accuracy level (0.70), plausible near-term frontier LLM accuracy (0.85), and demanding target accuracy (0.95). Note that $A_{threshold}$ uncertainty is narrow at low target error rates (left side) and wider at higher target error rates (right side), reflecting the mathematical structure of error=reliance×(1−A). LLM: large language model.

The A=0.7 simulation condition is closest to the accuracy levels currently reported for general-purpose LLMs on complex clinical tasks [18,19], in which the predicted error rates for novice clinicians range from 0.184 (low-complexity tasks) to 0.265 (high-complexity tasks). At high task complexity, the condition most relevant to ambiguous clinical presentations, the predicted error rate of 0.265 implies that approximately 1 in 4 AI-supported clinical decisions would be incorrect when the system is used by a novice clinician at this accuracy level.

$A_{threshold}$ Analysis

Table 2 presents $A_{threshold}$ values, the minimum AI accuracy required to achieve a specified error rate, for each of the 9 experience-by-complexity combinations at 4 target error thresholds (5%, 10%, 15%, and 20%). For novice clinicians performing high-complexity tasks, the minimum AI accuracy values required to achieve error rates <10%, <15%, and <20% were 0.894, 0.838, and 0.779, respectively. Corresponding values for experienced clinicians performing low-complexity tasks were 0.806, 0.686, and 0.539, respectively. These

XSL•FO
RenderX

differences highlight the interaction between clinician experience, task complexity, and the minimum accuracy requirement for clinical use. Because the reliance model is calibrated on nonnursing behavioral data, these numerical thresholds should be read as illustrative outputs of the model rather than as nursing-derived empirical standards; their value lies in the relative ordering across user-and-task profiles rather than in the specific accuracy figures.

Table . $A_{threshold}$ values—minimum AI accuracy required to achieve specified error rate targets[a].

Experience and complexity	Error<5%	Error<10%	Error<15%	Error<20%
0 years				
Low	0.925	0.845	0.759	0.670
Moderate	0.939	0.874	0.807	0.736
High	0.949	0.894	0.838	0.779
2 years				
Low	0.922	0.839	0.749	0.653
Moderate	0.937	0.870	0.800	0.726
High	0.947	0.891	0.834	0.773
10 years				
Low	0.909	0.806	0.686	0.539
Moderate	0.929	0.851	0.766	0.670
High	0.942	0.879	0.812	0.740

[a]$A_{threshold}$ is the smallest AI accuracy value $A \in [0, 1]$ at which the calibrated model's predicted mean error rate falls below the specified error rate target, computed analytically from the closed-form quadratic expression derived from the linear reliance specification. Values are rounded to 3 decimal places and were computed from the full-precision calibrated coefficients; exact coefficient values are available in the repository.

Bootstrap propagation of calibration uncertainty into $A_{threshold}$ values revealed an important asymmetry: although β_A has a wide bootstrap 95% CI, the $A_{threshold}$ values are tightly bounded. For the novice×high-complexity combination, the bootstrap 95% CIs for the $A_{threshold}$ to achieve error rates of 10%, 15%, and 20% were 0.877 - 0.898, 0.814 - 0.845, and 0.750 - 0.792, respectively. This tight propagation reflects the mathematical structure of error=reliance×(1−*A*): at low target error rates, the (1−*A*) factor must be small, which constrains *A* to lie close to 1 regardless of the exact value of β_A within its CI. Correspondingly, across the accuracy range currently reported for general-purpose LLMs on complex clinical tasks [18,19], the predicted error rate for novice clinicians on high-complexity tasks ranges from approximately 0.26 at the upper end of that range to approximately 0.41 at the lower end. The conclusion that AI systems operating in this accuracy range yield error rates well above stringent targets for this user-and-task combination is robust across the bootstrap distribution of the calibrated coefficients.

Figure 2B presents the $A_{threshold}$ function graphically, plotting the required AI accuracy against the target error-rate threshold for 5 representative experience-by-complexity combinations. Horizontal reference lines mark a reference LLM accuracy level (0.70), plausible near-term frontier LLM accuracy (0.85), and demanding target accuracy (0.95). At a reference accuracy level of 0.70, a total of 4 of the 9 cells achieve predicted error rates <20%: the 3 low-complexity cells (ranging from 14.5% for experienced clinicians to 18.4% for novices) and the experienced×moderate-complexity cell (18.5%). The remaining 5 cells—comprising novice and 2-year-experience clinicians on moderate- or high-complexity tasks, plus experienced clinicians on high-complexity tasks—have predicted error rates ranging from 21.6% to 26.5%, consistently exceeding a 20% error rate.

Sensitivity Analysis

When each of the 4 literature-fixed coefficients (β_E, β_C, β_{AE}, and β_{AC}) was varied by ±20% from its baseline value, the overall error ranking of the 27 cells was nearly preserved in every perturbation. Across all 8 perturbations (4 coefficients×2 directions), the Spearman rank correlation between the perturbed and baseline cell-level error rankings ranged from 0.991 to 1.000, with a mean of 0.998 (SD 0.003). The maximum absolute change in any cell's predicted error rate across all perturbations was 0.020, occurring for the β_E+20% perturbation in the experienced×moderate-complexity×*A*=0.5 cell (baseline 0.273; perturbed 0.253). These results indicate that the principal conclusions of the simulation—the tiered error-rate structure of the 27 cells and the $A_{threshold}$ values reported in Table 2—are robust to moderate perturbation of the literature-fixed coefficients.

Joint Decision Model and Extended Robustness

Under the joint human-AI decision model, the principal conclusion for the highest-risk condition was unchanged. For novice clinicians performing high-complexity tasks, the minimum AI accuracy required to keep predicted team error below 10% moved only from 0.894 at $p_c \to 1$ to 0.917 at p_c=0.6, and the threshold for the<20% target moved from 0.779 to 0.818 across the same range; because reliance is high in this cell, the override path contributes little, and clinician accuracy has

XSL•FO
RenderX

limited leverage. A qualitatively different pattern emerged in the lowest-deference cell (experienced clinicians on low-complexity tasks), where team error acquired an irreducible floor equal to $(1-R(A=1))\times(1-p_c)$. This floor grew from 0% at $p_c\to1$ to 8.6% at p_c=0.8 and 17.1% at p_c=0.6, so that the<10% target became unreachable by any AI accuracy once p_c fell to 0.7 or below. This structural feature—that improving AI accuracy alone cannot drive team error below the clinician's own error contribution—indicates that a single accuracy number is insufficient and that the human contribution to the joint decision must be represented. Under the asymmetric variant, allowing clinicians to correct a wrong recommendation (ρ<1) lowered the required accuracy substantially (for the novice×high-complexity cell at the <20% target, from 0.779 at ρ=1 to 0.673 at ρ=0.7 and 0.516 at ρ=0.5), indicating that the primary model is conservative with respect to correction.

The extended sensitivity analyses reinforced the ±20% results. Under wide one-at-a-time perturbation (up to ±100% and sign reversal of each literature-fixed coefficient), the novice×high-complexity threshold was mathematically invariant to β_E and β_A (both multiply the experience term, which is 0 in that cell) and varied only with the complexity-related coefficients; even under a full sign reversal of β_C, the required accuracy for the <10% target remained between 0.805 and 0.900, and the rank ordering of the 27 cells was preserved (Spearman ρ≥0.77 across all perturbations, and ρ>0.95 for most). In the global Monte Carlo analysis (50,000 draws per prior), the theory-signed prior yielded a novice×high-complexity $A_{threshold}$ with median 0.894 (5th-95th percentile 0.863 - 0.900) for the <10% target and 0.780 (5th-95th percentile 0.709 - 0.800) for the <20% target, with the required accuracy exceeding 0.70 in 100% and 97.4% of draws, respectively. Even under the fully sign-agnostic prior, in which every assumed coefficient sign was permitted to reverse, the <10% threshold for this cell retained a median of 0.844 and exceeded 0.70 in 84.4% of the sampled parameter space; values in the low tail arose only under sign combinations contrary to the theoretical expectations. Finally, both bounded alternative reliance structures fit the 9 calibration points essentially as well as the linear form (RMSE 0.0542 for the logistic and concave-saturating forms vs 0.054 for the linear form) and produced near-identical thresholds for the novice×high-complexity cell (0.900 and 0.794 - 0.795 for the <10% and <20% targets, respectively), indicating that the conclusions are not an artifact of the linear specification. Multimedia Appendix 1 summarizes the joint-model and global-sensitivity results.

Discussion

Principal Findings

In this study, an empirically calibrated simulation model was developed to quantify the AI accuracy required to achieve specified error rate targets in nursing decision-making across combinations of clinician experience and task complexity. Three principal findings warrant emphasis. We emphasize at the outset that the contribution of this work is a reusable, model-agnostic theoretical framework rather than an evaluation of any particular AI system. Its value lies in the mapping it defines from AI accuracy, clinician experience, and task complexity to a predicted error rate and a corresponding minimum-accuracy requirement—a mapping that does not depend on which model is current or on the specific accuracy figure entered into it.

First, the moderate accuracy levels currently reported for general-purpose LLMs on complex clinical tasks [18,19] fall within an operating zone where the predicted error rates exceed stringent targets for novice clinicians performing complex tasks. At the upper end of this reported range (approximately 0.70), the simulation predicts an error rate of approximately 0.26 in the novice×high-complexity cell—rising to roughly 0.41 at the lower end of the range—substantially exceeding the stringent error targets relevant to autonomous clinical decision support in high-risk clinical scenarios.

Second, the calibrated reliance model—grounded in 9 empirical data points from 3 independent randomized experiments (total N=3502)—indicates that human reliance on AI recommendations rises monotonically with AI accuracy but at a modest rate (β_A=0.20). This slope is considerably shallower than the reliance-accuracy relationships assumed in some theoretical frameworks and reflects the cumulative evidence that users calibrate their reliance in response to AI accuracy, but do so imperfectly and with substantial residual reliance even on low-accuracy systems. Because reliance does not rise steeply enough to offset the declining AI failure probability at high accuracy levels, the predicted clinical error rates in this model decrease monotonically as AI accuracy increases, without an interior maximum. The clinical implication is that no "dangerous middle" region exists in which error rates peak; the clinical concern, rather, is the absolute magnitude of error rates across a broad low-to-moderate accuracy range.

Third, $A_{threshold}$ values, the minimum AI accuracy required to achieve a specified error rate target, exhibit a pronounced dependence on clinician experience and task complexity. For the highest-risk combination (novice clinicians performing high-complexity tasks), achieving an error rate <10% requires AI accuracy of at least 0.89, and achieving an error rate <20% requires accuracy of at least 0.78. For experienced clinicians performing low-complexity tasks, the corresponding thresholds are 0.81 and 0.54. These differences, spanning up to 24 percentage points of the required accuracy across user-and-task profiles (at the <20% error target), indicate that a single accuracy benchmark cannot meaningfully govern clinical use decisions; the threshold depends on the user-and-task context.

Comparison With Prior Work

The predictions of the proposed model converge with findings from 2 independent lines of empirical research on human-AI interaction.

First, in the AI-assisted decision-making literature, the calibrated model is grounded directly in the reliance data from Lu and Yin [15] and Yin et al [14], representing 3 randomized experiments with a combined sample of 3502 participants. The linear form of the model aligns with the empirically observed monotonic relationship between AI accuracy and human reliance, and the absence of an interior reliance maximum in the range $A \in [0.5, 1.0]$, observed in both studies, directly shaped the structural

XSL•FO
RenderX

form of the reliance equation. This empirical basis distinguishes the present framework from earlier theoretical treatments that posited nonlinear reliance patterns without supporting behavioral data.

Second, in the clinical decision support literature, Kücking et al [16] reported that AI recommendation correctness exerted a strong bidirectional influence on the diagnostic performance of 223 physicians and nurses (OR 10.0; P<.001 for correct AI recommendations; reciprocal declines for incorrect recommendations). They also found that longer work experience was associated with higher diagnostic accuracy (OR 1.89), and formal qualifications further improved accuracy (OR 1.40). These clinical expertise effects are directionally consistent with the negative experience coefficient (β_E=−0.20) specified a priori in the present model. In a related study by the same group [27], the overall human diagnostic accuracy averaged 79.3% (up to 85% in the formally qualified subgroup); by comparison, general-purpose LLMs have been reported to achieve lower accuracy on complex clinical tasks [18,19], situating the operating range explored in the present simulation within a clinically meaningful band relative to human performance.

The introduced $A_{threshold}$ framework is best understood in relation to 3 established frameworks for human-automation interaction. Lee and See [10] proposed a process-oriented framework in which trust calibration determines appropriate reliance but did not provide quantitative guidance for translating system accuracy into use case decisions. Parasuraman and Riley [9] articulated a use/misuse/disuse/abuse taxonomy that classifies human-automation interaction failure modes but treats accuracy as an input among many rather than as a use-determining quantity. More recently, the literature on trustworthy AI [6] has emphasized explainability, fairness, and accountability as design principles, but has generally not specified accuracy thresholds for clinical use.

The present framework differs from prior approaches in 3 ways. First, it converts a single quantitative input—AI accuracy on the intended task—into a deployment decision using an empirically calibrated function. Second, it explicitly adjusts the deployment threshold based on user experience and task complexity, recognizing that no universal accuracy cutoff is appropriate across different use cases. Third, the graphical guidance provided in Figure 2B allows clinicians and administrators to read off the minimum required accuracy for a specific error tolerance and user-task profile without requiring statistical expertise. These properties make the $A_{threshold}$ framework complementary to, rather than competitive with, existing process- and design-oriented frameworks: $A_{threshold}$ provides a quantitative gating criterion that can be applied alongside trust calibration and trustworthy AI principles in deployment review processes.

Taken together, the present framework is consistent with both the quantitative reliance patterns observed in general-purpose AI-assisted decision-making and the qualitative expertise effects observed in clinical decision support. The principal gap in the empirical foundation—behavioral reliance data collected specifically in nursing populations performing clinical decision-making tasks across multiple AI accuracy levels—remains a priority for future research.

Theoretical Integration

The finding that $A_{threshold}$ varies strongly with task complexity can be interpreted through the lens of dual-process theory [28]. At low task complexity, system 2 (analytical) processing may remain engaged even when AI accuracy is moderate, because the clinician retains sufficient cognitive resources to evaluate the AI recommendation independently. At high task complexity, by contrast, system 1 (automatic) processing may predominate, as cognitive resources are preferentially allocated to the task itself rather than to critical evaluation of the AI recommendation. This asymmetry provides a theoretical rationale for the model's larger complexity-by-accuracy interaction coefficient and for the model-implied result that novice clinicians, who have not yet developed efficient system 2 strategies for clinical reasoning [21,22], face the most stringent AI accuracy requirements.

Within the framework of Lee and See [10], the model implies that appropriate reliance is unlikely to be fully achieved through user education or interface design alone when AI accuracy falls substantially below the $A_{threshold}$ for the relevant user-and-task combination. In such contexts, the residual error rate is a function of system accuracy rather than of user awareness, and the appropriate intervention is either to restrict AI use to user-and-task combinations for which the $A_{threshold}$ is met or to improve AI accuracy itself.

A further implication concerns the durability of the framework, as language models continue to improve. Because the $A_{threshold}$ framework maps any given AI accuracy onto a predicted error rate and a corresponding minimum-accuracy requirement, its utility does not depend on the accuracy level of any particular contemporary model. As model performance advances, the same framework can be reapplied to locate an improved system within the accuracy-error landscape and to re-evaluate which user-and-task combinations it can safely support. The specific operating range attributed here to current general-purpose LLMs is thus a movable reference point within a framework that is itself invariant to such change.

Clinical Implications

The following implications are exploratory and contingent on behavioral validation in nursing settings; they describe how the $A_{threshold}$ framework might inform practice rather than offering validated recommendations and should be interpreted in conjunction with the limitations. In particular, a system's meeting a given $A_{threshold}$ on a benchmark should be treated as a necessary but not a sufficient condition for nursing use, and the framework must not be interpreted as authorization to deploy a system without behavioral validation in the relevant nursing context.

First, the minimum AI accuracy required for clinical use should be specified as a function of the intended user and task, not as a single benchmark. Although an AI system operating at the moderate accuracy levels typical of current general-purpose LLMs on complex clinical tasks [18,19] may be suitable for use by experienced clinicians in low-complexity tasks, it is

XSL•FO
RenderX

predicted to produce error rates >25% when used by novice clinicians in high-complexity decision-making. Therefore, clinical use decisions should be based on the specific $A_{threshold}$ value that corresponds to the intended user population and task profile, rather than on the raw AI accuracy value alone. Moreover, the tolerable error rate is itself context-dependent—shaped by the clinical setting, the severity of potential harm, the degree of human supervision, and whether the system is used in a supportive or an autonomous capacity—so a target that is reasonable for an educational support tool may be inadequate for high-risk acute care.

Second, as AI is increasingly integrated across nursing practice and curricular reform has been called for to prepare nurses to work safely alongside these technologies [29], nursing education programs should incorporate explicit instruction on the relationship among AI accuracy, user experience, and clinical error rates. Students should understand that AI systems in the low-to-moderate accuracy range typical of current general-purpose LLMs may be inadequate for autonomous use in high-complexity clinical decisions. In these settings, AI should augment, not replace, clinical judgment. The $A_{threshold}$ framework offers a practical decision tool for this educational purpose.

Third, clinical workflows could adopt differentiated deployment protocols informed by the $A_{threshold}$ framework. When the current AI accuracy for user-and-task combinations falls below the relevant $A_{threshold}$, enhanced monitoring safeguards, such as mandatory verification steps, second-clinician review, or confidence-based routing, should be applied preferentially. These measures provide a practical intermediate solution while AI accuracy continues to increase toward levels suitable for autonomous use.

Fourth, regulatory and institutional review processes for clinical AI decision support could be informed by encouraging deployment proposals to specify the intended user population and task profile and to consider the corresponding $A_{threshold}$. Current regulatory frameworks do not typically request this level of user-and-task-specific justification; the $A_{threshold}$ framework is offered as a candidate quantitative input to such review, pending behavioral validation, rather than as a validated regulatory standard. This need is underscored by recent calls for explicit regulatory oversight of LLMs used in health care [30,31].

Limitations

Several limitations merit consideration.

First, although the accuracy-related coefficients of the reliance model were empirically calibrated against published behavioral data, the framework itself remains a theoretical construct, and its predictions require direct behavioral validation. Calibration confirms that the monotonic reliance slope is consistent with empirical observations in AI-assisted decision-making, but it does not establish that the noncalibrated coefficients (β_E, β_C, β_{AE}, and β_{AC}) accurately reflect nurses performing clinical tasks. The same caution applies to the joint decision model introduced in response to review: the clinician's independent accuracy (p_c) and the correction factor (ρ) are illustrative parameters rather than calibrated quantities, so the joint-model results should be read as a structured sensitivity analysis over a plausible range of clinician behavior—showing which conclusions are robust to, and which depend on, the human contribution to the decision—rather than as point predictions for any specific clinician accuracy. The framework should therefore be interpreted as a decision-support and hypothesis-generating tool rather than as a validated predictive model for individual clinical use.

Second, the accuracy levels used to contextualize the simulation's operating range were drawn from published benchmarks of general-purpose LLMs on complex clinical tasks rather than from a nursing-specific evaluation. Reported LLM accuracy varies substantially across models, prompting strategies, task types, and clinical domains, and the accuracy of frontier LLMs on complex clinical tasks remains an active area of research. The operating range examined here should therefore be regarded as an illustrative band informed by the current literature rather than as a definitive estimate of any specific system's clinical performance.

Third, calibration data were drawn from 3 studies that differed systematically in baseline reliance levels (Lu and Yin [15]: ~0.65; experiment 1 by Yin et al [14]: ~0.78; and experiment 3 by Yin et al [14]: ~0.82). The linear model averages across this heterogeneity, producing an RMSE (0.054) larger than the SEs of individual study means. Therefore, the calibrated slope (β_A=0.201) should be interpreted as a central tendency across heterogeneous contexts rather than a precise parameter applicable to any specific setting. Part of this heterogeneity may reflect methodological differences in how AI accuracy was manipulated (stated, observed, or designed), which the calibration pooled as proxies for the underlying *A* variable. The heterogeneity is informative and motivates future research parameterizing contextual factors beyond AI accuracy. With only 3 independent calibration studies, the study-level bootstrap has a limited sample space, so the reported CIs should be viewed as lower bounds on the true uncertainty. Consistent with this, the $A_{threshold}$ values are reported to 3 decimal places to reflect the numerical precision of the simulation, not the empirical precision of the underlying parameter, which is bounded by a wide CI whose lower limit approaches 0. The thresholds are therefore best interpreted in relative and ordinal terms—comparing the accuracy demands of different user-and-task profiles—rather than as exact accuracy targets to be applied at the reported number of significant figures.

Fourth, the calibration data were derived from studies in which crowdworkers predicted speed-dating outcomes rather than clinicians making clinical decisions. Although this is the most empirically rich reliance-by-accuracy source currently available, the clinical context gap is substantial. Clinicians may exhibit baseline reliance, accuracy sensitivities, and experience effects that differ from those of crowdworkers, and the task complexity assigned to speed-dating prediction (*C*=0.5) reflects a qualitative judgment rather than direct measurement. Even so, the directional structure of the model is consistent with recent experimental evidence from clinical populations that include

XSL•FO
RenderX

nurses. In a web-based experiment with 223 dermatologists, reliance on AI was stronger for correct than for incorrect advice and decreased with greater medical experience [32]. More directly, in a wound-maceration study, 223 physicians and nurses made decisions that were sensitive to whether the AI recommendation was correct or incorrect [16], and a related report measuring the rate of agreement with incorrect recommendations found that higher diagnostic performance and certified wound-care training were associated with lower agreement [33]. These patterns match the positive accuracy-reliance slope and the experience-based attenuation encoded in the model, supporting cautious extrapolation of its directional structure to clinical settings. Nursing-specific calibration data obtained across multiple AI accuracy levels would substantially strengthen the empirical foundation of the framework.

Fifth, the linear reliance specification was chosen for parsimony and tractability, since 9 aggregate calibration points are insufficient to identify more elaborate functional forms. Alternative specifications (logistic, power-law, and segmented-linear) might provide superior fit with richer data. The linear form should therefore be interpreted as the simplest specification consistent with the available data, not as a claim that the underlying reliance-accuracy relationship is truly linear.

Sixth, the model does not incorporate contextual factors—such as time pressure, team dynamics, organizational accountability, and environmental stressors—that are known to influence clinical decision-making. These factors likely contribute substantially to real-world reliance and to the observed between-study heterogeneity. Future investigations should explicitly parameterize the most influential contextual factors, which will require more calibration data than are currently available.

Seventh, the reliance and error expressions are clipped to [0, 1] to preserve their probabilistic interpretation. Within the reported 27-cell grid, clipping affected <1% of simulated values and did not materially alter the reported results. At extreme accuracy levels outside the reported grid, clipping becomes more frequent, and the linear reliance expression should not be extrapolated beyond its reported domain.

Conclusions

This study provides an empirically calibrated simulation framework for quantifying the AI accuracy required to achieve specified error rate targets in nursing decision-making. Calibration against 9 empirical data points derived from 3 independent randomized experiments (total N=3502) indicates that human reliance on AI rises gradually but modestly with AI accuracy. For the highest-risk combination—novice clinicians performing high-complexity tasks—the predicted clinical error rates remain above a stringent target (eg, <10%) when AI accuracy is below approximately 0.89. The moderate accuracy levels currently reported for general-purpose LLMs on complex clinical tasks [18,19] fall well below this threshold, suggesting that, on present evidence, such systems are not yet adequate for autonomous use by novice nurses on complex clinical decisions and should serve as an adjunct to, rather than a replacement for, clinical judgment. The $A_{threshold}$ framework introduced here provides a decision-theoretic tool for specifying minimum accuracy requirements as a function of clinician experience and task complexity, and it can inform AI deployment, nursing education, and regulatory policy. Direct behavioral validation in nursing populations remains an essential next step.

Acknowledgments

The author thanks Lu and Yin and Yin et al for making their experimental data and figures publicly available, which made empirical calibration possible. During the preparation of this work, the author used Claude (Anthropic) as a writing assistance tool to draft and revise sections of the manuscript in English, assist in the analysis of publicly available empirical reliance data, and generate Python code for model calibration and Monte Carlo simulation. After using this tool, the author reviewed and edited the content as needed and took full responsibility for the content of the publication.

Funding

The author declared no financial support was received for this work.

Data Availability

The data and code that support the findings of this study are openly available in the nursing-AI-error-thresholds repository on GitHub under the MIT License [34]. The complete reproducibility package includes all calibration scripts, the bootstrap procedure (2000 study-level iterations), the 27-cell factorial simulation, the joint decision model, and the extended (wide, global, and alternative-structure) sensitivity analyses, together with vector-format source files for every figure reported in this paper. Rerunning the figure-generation script from a clean Python ≥3.10 environment reproduces the calibrated coefficients (β_0=0.4708; β_A=0.2010), the bootstrap 95% CI for β_A (0.023-0.234), and all reported numerical results to at least 3 decimal places across platforms. The pseudorandom number generator was initialized with seed 42 using the NumPy default_rng interface, and the 27-cell factorial simulation used 10,000 Monte Carlo trials per cell. Analyses were conducted in Python (version 3.11) with NumPy (version 1.26) and SciPy (version 1.13). A preprint of this manuscript is available on SSRN [35].

Multimedia Appendix 1

Extended robustness analyses. (A) Minimum AI accuracy ($A_{threshold}$) required to keep predicted team error below the 10% and 20% targets under the joint human-AI decision model, plotted against the clinician's independent accuracy p_c, for the highest-risk (novice×high-complexity) and lowest-deference (experienced×low-complexity) cells. The primary model corresponds to $p_c \to 1$. In the lowest-deference cell, the team error acquires an irreducible floor that grows as p_c declines, so the 10% target becomes unreachable by any AI accuracy at $p_c \leq 0.7$. (B) Distribution of the novice×high-complexity $A_{threshold}$ from the global Monte Carlo sensitivity analysis (50,000 draws per prior) for the <10% and <20% targets, under a theory-signed prior and a fully sign-agnostic prior. The vertical line marks the reported estimate (0.894) and the dotted line the 0.70 anchor.

Abstract

Background: Artificial intelligence (AI) continues to expand into nursing and health care. Many examples of AI applications driven by machine or deep learning are in use. Examples include wearable devices or alerts for risk prediction. AI tends to be promoted by nonnurses, creating a risk that AI is not designed to best serve registered nurses. Community health nurses (CHNs) are a small but essential group. CHNs' familiarity with AI and their perceptions about its effect on their practice are unknown.

Objective: The research aims to understand CHNs' awareness, knowledge, and perceptions of AI in practice and gain insights to better involve them in AI.

Methods: An online cross-sectional Canadian survey targeting CHNs was conducted from April to July 2023. Descriptive statistics summarized respondents' characteristics and perceptions of AI, followed by a chi-square test used to determine a relationship between respondents' level of AI knowledge and their AI perceptions, with odds ratio (OR) to determine the strength of association.

Results: A total of 228 CHNs participated with varying response rates per question. Most respondents were female (172/188, 91.5%), average age of 45.5 (SD 11.7) years, and an average of 13.5 (SD 10.1) years of community practice experience. Most respondents (205/228, 89.9%) felt they welcomed technology into their practice. They reported their understanding of AI technologies as "good" (95/220, 43.2%) and "not good" (125/220, 56.8%). Overall, 39.6% (80/202) of respondents felt uncomfortable with the development of AI. They agreed that AI should be part of education (143/203, 70.4%), professional development (152/202, 75.2%), and that they should be consulted (195/203, 96.1%). Many respondents had concerns related to professional accountability if they accepted a wrong AI recommendation (157/202, 77.7%) or if they dismissed a correct AI recommendation (149/202, 73.8%). Respondents with "good" AI knowledge were significantly associated with, and twice as likely to indicate nursing will be revolutionized (*P*=.007; OR 2.28, 95% CI 1.25-4.18), nursing will be more exciting (*P*=.001; OR 2.52, 95% CI 1.42-4.47), health care will be more exciting (*P*=.004; OR 2.3, 95% CI 1.30-4.06), and agreed that AI is part of nursing (*P*=.01; OR 2.1, 95% CI 1.19-3.68). Respondents with "not good" AI knowledge were significantly associated with, and more likely to feel uncomfortable with AI developments (χ^2_1=4.2, *P*=.04; OR 1.84, 95% CI 1.03-3.3).

Conclusions: CHNs reporting "good" AI knowledge had more favorable perceptions toward AI. Overall, CHNs had professional concerns about accepting or dismissing AI recommendations. Potential solutions include educational resources to ensure that CHNs have a sound basis for AI in their practice, which would promote their comfort with AI. Further research should explore how CHNs could be better involved in all aspects of AI introduced into their practice.

Introduction

Background

Artificial intelligence (AI) covers a broad array of AI-driven applications supported by machine learning (ML) or deep learning, which have potential utility in health care and nursing practice. Many examples of AI-driven care applications exist, from wearable devices for automated detection of signs and symptoms [1], automated assessment of outcomes to support the need for a different level of care [2,3], client-specific automated predictions of risks [4-7], and bots to answer inquiries and send reminders [8]. Despite widespread uptake and use, AI is commonly driven by nonnurses (ie, scientists, engineers, and the technology industry) [9,10] and physicians [11]. The lack of participation by registered nurses (RNs) creates a risk that AI will not be designed to best serve RNs who are expected to use AI applications and their outcomes in clinical practice [11-13]. Likewise, it is unknown whether community health nurses (CHNs) have thought about how AI applications could change their practice or how AI might be useful to inform clinical practice.

The community setting has a smaller group of RNs compared to the acute care sector [14]. CHNs are RNs who provide essential services in a variety of roles (eg, home health, public health, and primary care) within community settings (eg, clients' home and schools) [15]. Home health clients are most often older adults with multiple comorbidities [2], or individuals who have chronic [16,17] and unstable conditions [18]. Public health clients can be any age, as the focus of care is on promoting better health with service delivery to groups or individuals [15]. Within these settings, CHNs make the best care decisions based on the information that exists, as well as considering other subtleties that can affect these decisions. Regardless of the setting in the community, CHNs have increased autonomy [15,17,19], and clients have reduced nursing oversight because of time between visits [20]. This decreases the amount and frequency of the client-specific data collected. Further, CHNs focus on human connections and building trustful relationships while recognizing the strengths of individuals and communities to promote and improve their health [15]. These features support the importance of having CHNs who understand the practice area involved in AI.

Nursing research within the community sector is expanding to include a focus on the use of AI (eg, ML) as a method to improve real-time risk predictions [5,20,21] and to assist with better planning or targeting of service delivery [16]. Although involving CHNs would be key to raising the right questions for AI, as well as advising and validating results [22], few researchers are reporting this type of CHN involvement in AI development. More commonly, researchers are using existing collected data [16,21,23]. This passive involvement misses the opportunity of actively involving CHNs who are familiar with the data they collect and how it may add insight to clinical issues. However, in one example, a nonnurse researcher [24] describes using CHNs to advise and evaluate throughout an AI project, concluding that nursing input validated outcomes and facilitated acceptance of the AI algorithm into practice. Hence, nursing involvement provides a relevant perspective and knowledge that influences their informed decisions, which ensures clinical relevance and accuracy of AI and related ML [24,25]. These revelations add impetus to examine CHNs' perceptions of AI in their practice and to consider how they could be better involved.

Purpose Statement

This study aims to establish a baseline understanding of Canadian CHNs' awareness, knowledge, and perceptions of current and future effects of AI on their clinical practice. This will help to gain insights into how CHNs could be better involved in AI. Therefore, the research questions guiding this study include: (1) Are CHNs aware of the emergence of AI, including ML applications, in nursing? (2) What are CHNs' main sources of knowledge for learning about current day-to-day AI? (3) How do CHNs describe their level of knowledge of AI technologies? (4) Is there a relationship between CHNs' level of knowledge of AI technologies and their perceptions of the effects of AI on clinical practice, professional accountability, and the usefulness of AI applications? (5) What AI competencies do CHNs perceive as being needed in their community practice?

Methods

Ethical Considerations

Research approval was granted from the University of Northern British Columbia (UNBC) Research Ethics Board (REB 6009080), April 2023, to conduct a single cross-sectional open survey using SurveyMonkey licensed through UNBC. The survey landing page included an informational letter to provide study details. After reading the information on the landing page, respondents were asked to voluntarily consent electronically to participate in the study. Upon confirmation of informed consent, participants were then given access to this survey. If a participant did not consent, they received a thank-you message, and access to the survey closed automatically. All aspects of data collection, storage, and analysis were password-protected and housed on an encrypted UNBC server. The invitations advertised a random draw of 5 e-gift cards at the end of the survey period as an incentive to participate in the survey.

Instrument Design

A total of 11 research papers, which used surveys to examine attitudes and perceptions toward AI, were screened for relevance to this research study's instrument design. Two papers [26,27] were validating their General Attitudes Artificial Intelligence Scale to classify individuals with positive or negative feelings toward AI. The remaining 9 research studies targeted RNs [28], nursing students [29], radiologists [30,31], physicians [32], medical students [33], a mix of health care professionals [34,35], and consumers [36]. All except Swan [28] had their survey questions included in the publication or supplemental information. A request to preview and use Swan's survey, if applicable, was granted (BA Swan, RN, PhD, personal communication, November 30, 2022).

Swan's survey was selected due to its purposeful design for use with nursing professionals. It included similar questions to the other previewed surveys, indicating that common survey topics

XSL•FO
RenderX

were covered. Further, Swan's survey was adapted by adding questions important to this study. In the adapted survey, the first question to address computer expertise was sourced from Schepman and Rodway [27], who suggested that individuals with computer expertise would be more positive about AI. Questions 32 and 33 were added from Esmaeilzadeh [36] with slight modifications to address professional accountability. More details on the survey and its adaptation are found in Multimedia Appendix 1. Swan's survey had not been tested or piloted before deployment of the survey (BA Swan, RN, PhD, personal communication December 21, 2022).

The revised survey was reviewed for clarity by a retired community nursing manager with over 35 years of community experience, as a public health nurse in direct care and management. It was confirmed that the survey took 20 minutes to complete, and a direct question exploring how nurses should be involved with AI was suggested. Therefore, Q37 "How should nurses be involved in artificial intelligence that influences their practice?" was added.

The final version consisted of 37 content questions (referencing aspects of AI) plus a demographic section, which was used to describe respondents' representation across Canada, as well as their level of experience and current position. The survey was recreated on the survey platform. Complete wording of each survey item and types of questions are found in Multimedia Appendix 1.

Recruitment

The target population was RNs licensed in Canada who practiced in the community setting (eg, home care and public health) or RNs who had a community nursing focus (eg, researchers, educators, administrators, and clinical informatic nurses). Collectively, the term CHNs will be used. The survey was only offered in English. The size of the targeted population was unknown. Canadian workforce data reported that 32,074 direct care RNs were employed in community health in 2023 [14]; however, this does not account for the others not providing direct care (eg, researchers, educators, and administrators) included in the population of interest. Therefore, an online calculator [37] was used with the parameters of 20,000 for an unknown population, distribution at 50%, with 5% margin of error and a 95% CI, indicating a sample size of 377 was needed. The emergence of AI into clinical practice remains a new field. Therefore, the power analysis was a reference point to guide this exploratory research study.

The participants were recruited by an "invitation to participate letter," which had the live link to the survey embedded into its content. This was shared through nursing sources by monthly newsletters, email lists (eg, existing organizational and collegial connections), and informal networks (eg, colleague-to-colleague and social media). Two national organizations, Community Health Nurses of Canada and Canadian Nursing Informatics Association, canvassed their membership by broadcast messages and posts in their monthly e-newsletter. Each provincial and territorial nursing association or licensing body was contacted by email, briefly explaining the research and asking if they would circulate it to their members. Licensing bodies recommended that the researcher contact the nursing associations. One provincial licensing body agreed to send out the invitations by email to their members who identified as working in the community and had previously consented to be contacted for research purposes. The nursing associations kept the invitation in their monthly newsletters, or posts on their social media sites, or sent by broadcast message to their members until the survey closed. The survey was live from April 24 to July 30, 2023.

Data Management

On the survey closure date, the full dataset was exported from the survey platform to SPSS Statistics (version 29; IBM Corp). All computer IP addresses were removed, as well as respondents who provided consent but did not complete any survey questions. As it was expected that CHNs may complete this survey using a shared workstation, multiple responses from the same IP address were included as long as they were completed at different times, for different durations, and represented unique participant responses. The use of the same IP addresses was limited to 10 instances and met the above criteria. The geographical locations were grouped into regions to determine Canada-wide representation: Eastern (Prince Edward Island, Newfoundland & Labrador, New Brunswick, and Nova Scotia), Central (Ontario and Quebec), Western (Manitoba, Saskatchewan, Alberta, and British Columbia), and Northern (Yukon, Northwest Territories, and Nunavut). Questions that offered "other" as a choice were reviewed and recoded into the appropriate existing choices already provided; otherwise, it was left as "other." All word responses were coded for a numerical value to enable analysis (eg, Likert scale responses). Surveys that were blank (n=5) were removed. Cases with missing data (greatest in the demographic section) were kept, thus maximizing the number of responses for any given question. Therefore, the count n/N and percent are presented per question, except for multiple response questions, where n values and percent are given, because participants could respond to more than one option. Chi-square analysis was conducted to examine the relationship between respondents' reported AI knowledge (Q6) and respondents' perceptions of AI in their practice (Q10-Q20 and Q22-Q35, Q21 "other" was not included). All questions were examined for their missing or incomplete data. Variation in response rates could be due to respondents' choices not to answer or complete the survey. Therefore, to minimize the potential for response bias, all questions with a less than 15% missing data rate were kept. The core set of survey questions used to examine the research questions met this proportion of missing variables, with response rates as follows: Q6 (220/228, 96.5%), Q10-Q20 (206/228, 90.4% to 208/228, 91.2%), and Q22-Q35 (202/228, 88.6% to 207/228, 90.8%). The missing data for these questions is as follows: Q6 (3.5%), Q10-Q20 (range 8.8% to 9.6%), and for Q22-Q35 (range 9.2% to 11.4%).

Data Analysis

Both descriptive and inferential statistics were used to examine the data. Descriptive analysis summarized respondents' characteristics and their perceptions of AI in nursing. Inferential statistics examined the relationship between their reported AI

XSL•FO
RenderX

knowledge (Q6) and their perceptions of the current and future effects of AI on nursing and health care.

The chi-square test for independence was used to determine an association between CHNs reported level of knowledge of AI technologies (independent variables) and their perceptions of the effects of AI (dependent variables). The CHNs were grouped by their reported level of knowledge of AI technologies to allow for comparison. CHNs described their level of knowledge of AI technologies as "excellent," "very good," "good," "fair," or "none." They were grouped as "good" level of knowledge if they indicated "good" to "excellent" and "not good" level of knowledge if they indicated "fair" or "none." The reference category chi-square test for independence was a primarily "good" level of AI knowledge; however, a "not good" level of AI knowledge was the reference category for Q26 (comfort with AI development), Q32 (concern with AI offering wrong recommendation), and Q33 (concern with dismissing appropriate AI recommendation) to promote ease in explaining the results. All statements related to CHNs' perception or attitudes about AI were a 5-point Likert scale from strongly agree (5), agree (4), neutral (3), disagree (2), and strongly disagree (1). The responses for these questions were grouped as "agree" if the respondent indicated "agree" or "strongly agree" and grouped as "not agree" if they indicated "neutral," "disagree," or "strongly disagree." Neutral was grouped with "not agree" because it was interpreted that this group of respondents had no definitive feeling either way on the subject. As the aim of the research was to gain an understanding of how to better involve nurses in AI, it was concluded that these "neutral" respondents, along with "not agree," may need more targeted strategies to better involve them. Further, the transformed response "agree or not agree" was clarified by the sentiment being examined to ease understanding. The dependent variables were considered: comfortable or not comfortable with AI development, AI applications useful or not useful, effects of AI agree or not agree, and professional accountability concerned or not concerned. Odds ratios were calculated for chi-square tests that were significant to determine the strength of association.

Correction (ie, Yates and Bonferroni) methods for statistical testing were not used. Yates continuity correction was not used because the sample size was considered large enough (range 202 to 208) to support a Pearson chi-square [38]. It is noted that the item "nurse should be consulted" produced cells under 5 (not agree); however, this seemed a reasonable result and would not benefit from Yates correction. The Bonferroni post hoc was not used because it can be too restrictive [39]. The Bonferroni post hoc (0.05/25=0.002) is given for reference only and includes the 25 items (Q10-Q20 and Q22-Q35) examined for association.

The open-text question asking the respondents "How should registered nurses be involved in AI?" was examined for types of responses. Some examples of these responses included how CHNs could be engaged in AI technologies, for example, education, advising, or consulting. These responses were quantified with the frequencies reported.

Results

Overview

A total of 296 potential respondents opened the survey, 261 met recruitment criteria, with 233 (89.3%) providing consent. As reported, blank surveys (n=5) were not included. A total of 228 surveys were included in the analyses. The response rate fluctuated per question, with the response rate better at the start of the survey and waning by the final demographic section. The item, "community years experience," had the most nonresponses (52/228, 22.8%).

Sample Characteristics

Sample characteristics (Table 1) helped to describe the sample that responded to the survey. The respondents' average age was 45.5 (SD 11.7) years, with 58.4% (104/178) younger than 50 years. Most respondents identified as female (172/188, 91.5%). The average overall years of experience for RNs was 19.8 (SD 12.2) years, with most (161/179, 89.9%) ranging from 5 years to over 35 years of experience. For community practice, the average years of experience was 13.5 (SD 10.1) years, with many (129/176, 73.3%) ranging from 5 years to over 35 years of experience. The sample had representation from the 4 Canadian regions: Eastern (47/186, 25.3%), Central (72/186, 38.7%), Western (65/186, 34.9%), and Northern (2/186, 1.1%). The practice descriptions are multiple-response questions. The reported practice settings (Table 2) included public health (65/191, 22.3%), home care (56/191, 19.2%), community health centers (44/191, 15.1%), primary care (41/191, 14%), and case management (16/191, 5.5%). Approximately half indicated they provided direct care (108/191, 51.4%), and the majority (115/190, 60.5%) held a bachelor's degree.

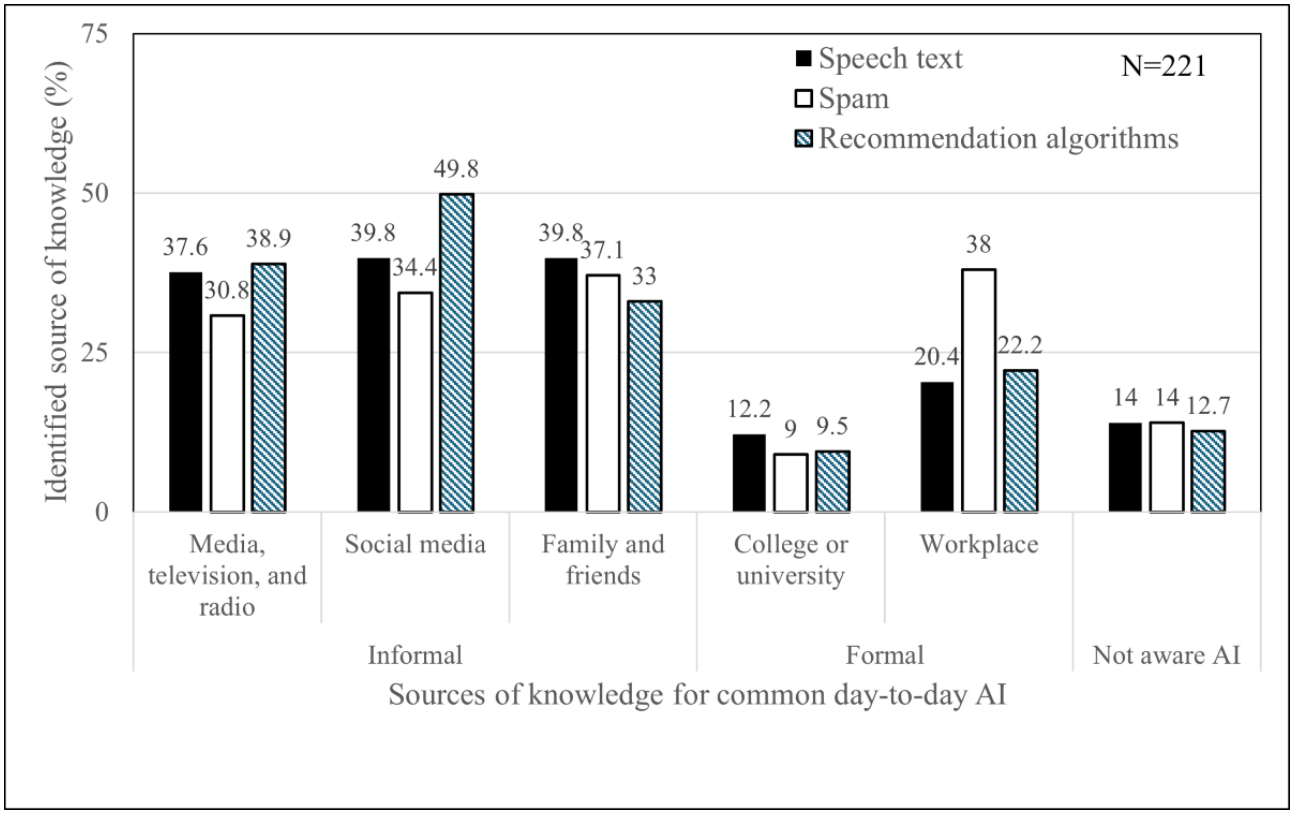
Acceptance of Technology and Competent Users of Technology

The survey questions 1 and 2 were used to explore the CHNs' acceptance of technology into their practice, and how they described their computer use. Almost all participants (205/228, 89.9%) agreed or strongly agreed to welcoming technology into their practice. More than half (129/227, 56.8%) identified as competent users of the internet and standard applications, and another 36.6% (83/227) indicated they were users of specialist applications. The survey, included in Multimedia Appendix 1,

XSL•FO
RenderX

is subdivided into sections related to the headings addressing each of the research questions.



CHNs' Awareness of the Emergence of AI, Including ML Applications, in Nursing

CHNs' awareness of AI (Q8) in health care was more prevalent than their awareness of AI in nursing. The respondents were aware of AI (multiple response questions) in health care (123/220, 55.9%), but fewer were aware of AI in nursing (67/220, 30.5%). This was similar for ML and deep learning (Q9): respondents had heard of it in health care (84/220, 38.2%), and fewer had heard of it in nursing (35/220, 15.9%).

CHNs' Main Sources of Knowledge for Learning About Current Day-to-Day AI

The key sources of knowledge for learning about current day-to-day AI (Q3-Q5) varied between informal and formal methods. The respondents' major source of knowledge (multiple response questions) of common forms of day-to-day AI applications (Figure 1; ie, speech-text, spam, and recommendation algorithms) was informal resources such as media, television, or radio (range 68/221, 30.8% to 86/221, 38.9%); social media (range 76/221, 34.4% to 110/221, 49.8%); and family and friends (range 73/221, 33% to 88/221, 39.8%). Formal sources were indicated less often: colleges and universities (range 20/221, 9% to 27/221, 12.2%) and workplace (range 45/221, 20.4% to 84/221, 38%). It is worth noting that some respondents were not aware that these applications (speech-to-text, spam, and recommendation algorithms) were forms of AI (range 28/221, 12.7% to 31/221, 14%).

Figure 1. Respondents' key sources of knowledge for day-to-day artificial intelligence. AI: artificial intelligence.

CHNs' Description of Their Level of Knowledge of AI Technologies

Respondents described their understanding of the technologies used in AI (Q6) as none (42/220, 19.1%), fair (83/220, 37.7%), good (67/220, 30.5%), very good (23/220, 10.5%), and excellent (5/220, 2.3%). These results were grouped into 2 levels of AI knowledge: "good" level of knowledge included good to excellent (95/220, 43.2%), and "not good" level of knowledge used fair and none (125/220, 56.8%). Level of AI knowledge (Q6) was used in the chi-square test, as AI was more commonly known with a more balanced representation. For ML or deep learning (Q7), it was a similar trend, more nurses indicated "not good" level of knowledge (148/220, 67.3%) than "good" level of knowledge (72/220, 32.7%).

The Relationship Between CHNs' Level of Knowledge of AI Technologies and Their Perceptions of the Effects of AI on Clinical Practice, Professional Accountability, and the Usefulness of AI Applications.

Effects of AI on Clinical Practice

Questions 22 to 31 and 34 to 35 examined the respondents' perception of the effects of AI on their practice. An overview of respondents' perceptions indicated 39.6% (80/202) felt uncomfortable with the developments in AI, ML, and deep learning. Over half (133/206, 64.6%) of the respondents agreed that AI would revolutionize both health care and nursing. Few respondents agreed that the human nurse, 10.2% (21/205), or members of the interprofessional team, 12.6% (26/207), would

XSL•FO
RenderX

be replaced. Almost half of respondents felt AI would make nursing more exciting, 44.1% (89/202), and similarly, health care more exciting, 47.5% (96/202). Likewise, 44.8% (91/203) perceived AI to be part of nursing. Many respondents (143/203, 70.4%) felt that AI should be part of nursing education and included in professional development (152/202, 75.2%). Most respondents agreed they should be consulted (195/203, 96.1%) about AI, as well as having the opportunity to raise relevant nursing questions (189/202, 93.6%).

Examination with the chi-square test for independence (Table 3) was used to determine if there was a relationship between the respondents' reported AI knowledge and their perceptions of the potential effects of AI on clinical practice. For Q26, the reference category for level of AI knowledge was "not good." There was a significant relationship between respondents reporting "not good" level of AI knowledge and their perception of "feel uncomfortable" (ie, "agree" with statement) with AI developments (χ^2_1=4.2, *P*=.04; α=.05; small effect ϕ=.15). Respondents reporting "not good" AI knowledge were 1.84 (95% CI 1.03-3.3) times more likely to indicate developments in AI made them feel uncomfortable.

[a]AI: artificial intelligence.

[b]OR: odds ratio.

[c]RN: registered nurse.

[d]Reference category was set to ”good” for all variables with the exception of Q26 where the reference category was set to “not good.”

The remaining statements (Q22-Q25 and Q27-Q35) used the reference category “good” level of AI knowledge. There were significant relationships between “good” level of AI knowledge and the following perceptions. Respondents perceived AI would revolutionize nursing (χ^2_1=7.3, *P*=.007; α=.05; small to moderate effect ϕ=.19) and were 2.28 times more likely to agree that nursing would be revolutionized (95% CI 1.25-4.18). Respondents perceived AI would make both nursing (χ^2_1=10.1, *P*=.001, α=.05, small to moderate effect ϕ=.22) and health care (χ^2_1=8.3, *P*=.004, α=.05, small to moderate effect ϕ=.20) more exciting. Respectively, these respondents were 2.52 times more likely (95% CI 1.42-4.47) and 2.3 times more likely (95% CI 1.30-4.06) to perceive that AI will make nursing and health care more exciting. These respondents perceived that AI is part of nursing practice (χ^2_1=6.6, *P*=.01; α=.05; small to moderate effect ϕ=.18) and were 2.1 times more likely to agree that AI is part of nursing practice (95% CI 1.19-3.68).

There was no association observed between level of AI knowledge and perceived effects: for revolutionizing health care (*P*=.13) nor between level of AI knowledge and perceived effects for replacing human RN (*P*=.36) or replacing interprofessional team members (*P*=.69). There was no association between level of AI knowledge and perception that AI should be part of nursing education (*P*=.4), part of professional development (*P*=.16), nurses should be consulted (*P*=.68), or nurses should identify relevant nursing questions for AI (*P*=.15).

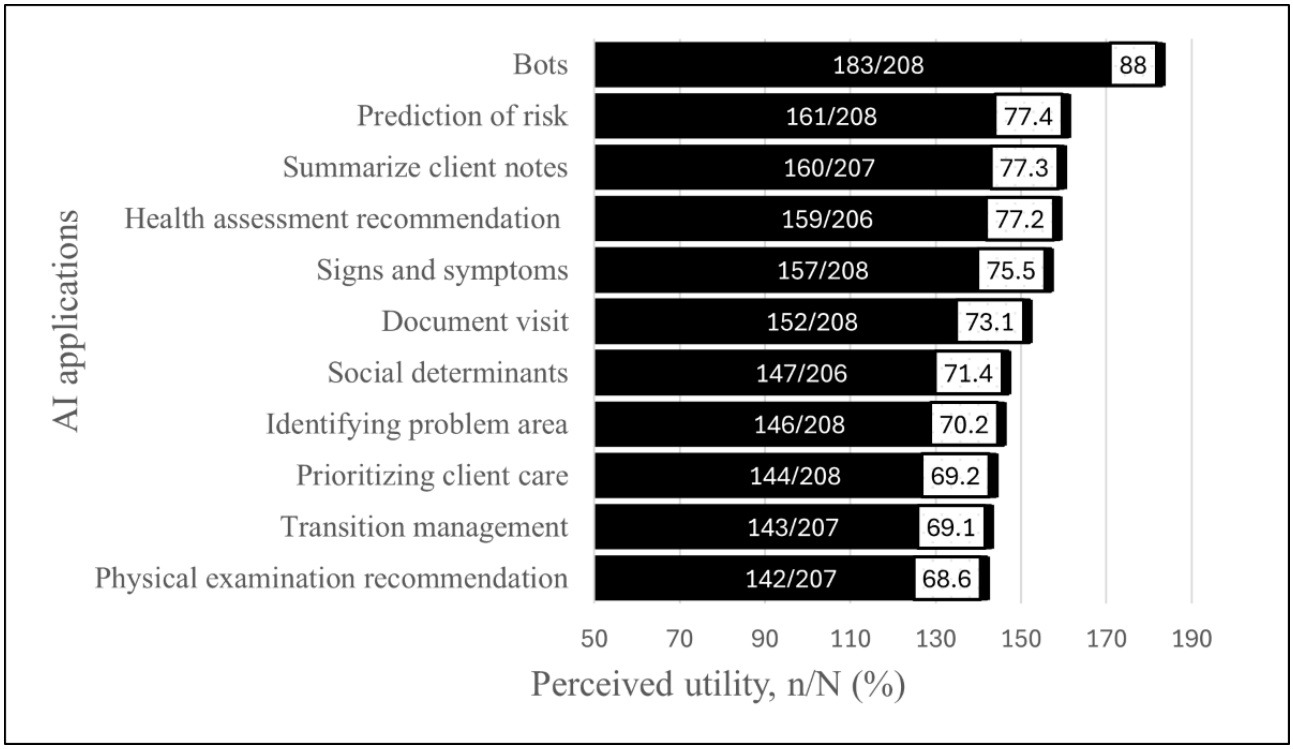
Professional Accountability

Two statements (Q32 and Q33) used “what if” scenarios to examine CHNs’ perceptions of AI and professional accountability. One described an AI providing the wrong recommendation, and the other described a correct recommendation that was dismissed by the nurse. Respondents expressed concern regarding their responsibility in both scenarios. The majority, 77.7% (157/202), were concerned if AI offered the wrong recommendation, and likewise, 73.8% (149/202), if an appropriate AI recommendation was dismissed. Examination with chi-square test for independence (Table 4) with “not good” as the reference category revealed no association between level of AI knowledge and perceived concern if AI provided a wrong recommendation (*P*=.06). Conversely, the chi-square test for independence suggested a significant association between a “not good” level of AI knowledge and perceived concern if a correct recommendation was dismissed (χ^2_1=3.98, *P*=.046; α=.05; small effect ϕ=.14). Respondents reporting “not good” AI knowledge were 1.9 times more likely to be concerned with dismissing an appropriate AI recommendation (95% CI 1.01-3.57).

Table . Respondents’ perceptions of concern with professional accountability related to their level of AI[a] knowledge.

Questions	Knowledge level	Concern		Chi-square (*df*)	ϕ	OR[b] (95% CI)	*P* value
		Agree n (%)	Not agree n (%)				
Q32 if AI offers wrong recommendations				3.7 (1)	0.14	1.9 (0.98-3.74)	.06
	Not good	95 (82.6)	20 (17.4)				
	Good	62 (71.3)	25 (28.7)				
Q33 if correct recommendation is dismissed				3.98 (1)	0.14	1.9 (1.01-3.57)	.046
	Not good	91 (79.1)	24 (20.9)				
	Good	58 (66.7)	29 (33.3)				

[a]AI: artificial intelligence.



[b]OR: odds ratio.

Usefulness of AI Applications

Q10-Q20 examined the respondents’ perceptions of the utility of various AI applications. Respondents perceived that overall, each AI application would be useful (Figure 2), with agreement ranging from 68.6% (142/207) to 88% (183/208). Most respondents indicated Q15 bots (183/208, 88%), Q18 risk prediction (161/208, 77.4%), and Q20 summarizing narrative text from a client’s notes (160/207, 77.3%) would be useful. Further examination to determine if the level of AI knowledge was associated with CHNs’ perception of the utility of AI application revealed that in all but one example, there was no association between level of AI knowledge and their perception of utility (Table 5). There was a significant association between a “good” level of AI knowledge and perception of utility for Q13 transition management (χ^2_1=7.9, *P*=.005, α=.05, small to moderate effect ϕ=.2). Respondents reporting “good” AI knowledge were 2.45 times more likely to agree that transition management would be useful (95% CI 1.3-4.63).

[b]OR: odds ratio.

AI Competencies CHNs Perceive as Being Needed in Their Community Practice

The survey (Q36) offered 10 competencies for respondents to indicate which were needed by CHNs (multiple-response question). The 3 competencies most identified as needed (Figure 3) were (1) communications, collaboration, and cross-functional knowledge (178/185, 96.2%); (2) knowledge of common uses and outcomes of AI (174/185, 94.1%); and (3) knowledge of common types of AI (173/185, 93.5%). The competency identified least was statistical knowledge, which also covered skills related to clinical analytics, data management, and algorithm awareness (117/185, 63.2%). Complete wording of each competency is found in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 3. Competencies identified by respondents as needed by CHNs to integrate AI into clinical practice. AI: artificial intelligence; CHN: community health nurse.

Insights on How CHNs Could Be Better Involved in AI

An open-ended question (Q37) asked how respondents thought they should be involved. It produced (70/228, 30.7%) responses, which provided insights into nurse involvement and their perspectives on related aspects of AI in their practice. Respondents expressed a need for further education (21/70, 30%) using phrases like “learn,” “knowledge acquisition,” “stay up to date,” and “education.” Most respondents (57/70, 81.4%) cited numerous roles or functions where nurses should be involved: raising relevant questions (5/70, 7.1%); advising and consulting (24/70, 34.3%); planning, development, and implementing (14/70, 20%); evaluation (12/70, 17.1%); change management (5/70, 7.1%); regulation, policy, and ethics (7/70, 10%); and all phases (13/70, 18.6%). They used terms like “key stakeholders” and “subject matter experts.” They felt nurses needed to be involved to make AI relevant. Respondents (7/70, 10%) specifically identified that direct care (front-line and end user) CHNs should be involved. Some respondents (8/70, 11.4%) referred to AI as a tool or an additional resource. Other respondents (13/70, 18.6%) acknowledged their apprehension with AI being introduced into practice. Respondents (6/70, 8.6%) referred to the need to be mindful about the human relationship with phrases like “relationships are key aspects of community health nursing” and “human connection care can not be replaced.”

Discussion

Principal Findings

The main findings indicated CHNs differ in their level of knowledge and perceptions of AI technologies in nursing and health care. Many CHNs have a limited awareness of AI emerging in health care and report even less awareness of AI emerging in nursing practice. The main sources of information for day-to-day AI applications are predominantly informal methods (eg, social media) compared to academic and workplace sources. Some CHNs are unaware that common day-to-day applications are AI-driven. Fewer CHNs describe their knowledge of AI technologies as “good.” However, the CHNs who describe their AI knowledge as “good” are twice as likely to be optimistic or have favorable perceptions of AI effects, such as revolutionizing nursing, making nursing more exciting, and agreeing that AI is part of nursing. Whereas CHNs with “not good” AI knowledge are almost twice as likely to feel uncomfortable with AI development. Regardless of the level of AI knowledge, most CHNs agree they should be involved in AI by consulting and raising nurse-relevant questions in various phases of AI development, such as implementation and ongoing evaluation. The results substantiate the need for appropriate AI education for CHNs to prepare them to participate in AI that will influence their practice.

CHNs have a limited awareness of AI emerging in nursing practice (30.5%), which aligns with results found in similar nursing research [28,40]. However, other questions in this current research are used to gain further insights into why their

XSL•FO
RenderX

understanding of various AI technologies might be limited. CHNs use informal (eg, social media, and family and friends) methods of learning about common day-to-day AI applications, with 12.7% (28/221) to 14% (31/221) of respondents being unaware that these common forms (ie, speech to text, spam, and recommendation algorithms) are driven by AI. This limited awareness could be related to relying on informal sources of knowledge. CHNs may turn to readily available sources of information because of convenience. Likewise, being aware of spam from work-related sources could be as simple as "don't see a reply, check your spam folder," while having no real understanding of the algorithms that recognize and reroute spam. This lack of understanding whether an application is driven by AI has been linked to clinical practice by another study [40] where 22% of Canadian nurses did not know if AI is used in their practice area. Similarly, Coakley et al [31] identified that approximately 40% of radiographers did not recognize work-related AI-driven applications. This raises a potential concern that CHNs may be using AI-driven applications within their practice unbeknownst to them. Lastly, over half (125/220, 56.8%) of CHNs describe their knowledge of AI technologies as "not good." This limited awareness of AI in nursing and lack of knowledge of AI technology highlights a knowledge deficit, stressing the importance of AI education for CHNs.

The composition of the survey sample strengthens the clinical value of the results. First, this Canadian sample is an experienced group of CHNs, both in years of practice as an RN and years of experience in the community sector. They describe themselves as competent and welcoming of technology. This was expected because Canada has been striving since 2000 to improve digital health connections (eg, electronic health records) within the Canadian health care system [41]. A current report [40] confirms a continual uptake in digital technology. This steady increase of new technologies into practice (eg, electronic health records and electronic assessments) emphasizes CHNs' adaptability and resiliency to new technologies in their practice, considering these decisions are made at higher levels in the organization rather than from staff who are expected to use them [42]. Second, more than half of the survey respondents provide direct care services. This means they are familiar with community practice, its clinical data, and provision of care at the client level, and have the potential to offer pragmatic insights. Third, this group of CHNs includes end users who are seldom involved in the development of AI. They are, however, important stakeholders in ensuring clinical relevance in new technology [22,24]. The various characteristics (eg, experienced, competent, and end users) of this CHN sample provide validity and relevance to the results.

A common technique for assessing the level of knowledge across surveys is asking the respondent to indicate their level of AI knowledge. Most surveys use this subjective method, finding fewer respondents rate their level of AI knowledge as "good" compared to "not good" level of knowledge) [28,32,40,43,44], aligning with the current study (level of knowledge "good" 95/220, 43.2% versus "not good" 125/220, 56.8%). None of the cited surveys uses the difference in knowledge level to compare groups and their perceptions.

The subjective evaluation of CHNs' level of AI knowledge may be underestimated or overestimated. However, professionally, CHNs self-reflect on practice and learning gaps, so they have familiarity in evaluating their competencies [45]. It seems plausible to use the self-identified AI knowledge level as a starting point to determine if there is a relationship between the level of knowledge and CHNs' perceptions of AI. The 2 groups of "good" and "not good" knowledge level of AI technologies in this study suggest that the level of AI knowledge affects some of the AI perceptions of CHNs.

The CHNs reporting "not good" level of knowledge are almost two times more likely to indicate that they are uncomfortable with the developments in AI. Intuitively, this makes sense. It can be argued that having "good" AI knowledge provides a method to evaluate the benefits or disadvantages of AI and perhaps provides some control [46]. CHNs reporting a "good" level of knowledge are more than two times more likely to feel nursing will be revolutionized, nursing and health care will become more exciting, and agree that AI is part of nursing practice. Therefore, CHNs with a "good" level of AI knowledge are more optimistic about the future effects of AI [46]. The differences between AI perceptions for CHNs with a "good" level of knowledge versus a "not good" level further stress the necessity for education and ongoing learning opportunities to decrease apprehension and promote optimism around AI [46].

Regardless of their level of knowledge, few CHNs believe that human RNs (21/205, 10.2%) or interprofessional team members (26/207, 12.6%) will be replaced by AI. This sentiment aligns with that of Swan [28]. The underlying belief that human touch is integral to nursing care, along with humans' ability to reconsider and change care when an unexpected situation arises, supports human RNs and other interprofessional members' continued importance to the care team [47-49]. CHNs' responses (Q37) defend the importance of human involvement: "relationships are a key aspect of community health nursing" and "human connection care can not be replaced." CHNs' belief that they will not be replaced does not address how they think their role within health care will change. This aspect should be examined in future research.

Professional accountability is a central feature for all regulated professionals. Several studies include some reference to the issue (eg, medical liability). This current study demonstrates a mixed outcome. There is no association between the level of AI knowledge and concern with AI providing a wrong recommendation, versus an association between the level of AI knowledge and concern with dismissing a correct recommendation. Still, the clinical importance should be addressed because most CHNs, regardless of their level of AI knowledge, have concerns about who would be held responsible for either accepting a wrong recommendation (157/202, 77.7%) or dismissing a correct recommendation (149/202, 73.8%). Other studies confirm that professionals have concerns about the use of AI in practice [32,40,43]. Further research needs to explore what CHNs feel they require to help address and remediate their concerns.

Although CHNs have a limited understanding of AI, more than two-thirds perceived the examples of AI-driven applications as

XSL•FO
RenderX

useful. It suggests that, superficially, they perceived a value in the application to their practice setting. Positive perceptions of the utility of AI applications trend across surveys [28,33,40,43]. However, it is unknown why CHNs perceive the AI applications as useful to them; that is, whether it is the function of replacing a task or the function of supporting decision-making that is important. Future research should follow the open text response "start by asking nurses what they feel could be automated," thus gaining an understanding of what makes an application useful.

A more comprehensive picture of how CHNs should be involved in AI becomes apparent through the open text responses. First, CHNs confirm their need to "learn," for "knowledge acquisition," to "stay up to date," and "education" as important prerequisites to being involved in AI. Although the quantitative sample identifies the necessity of AI to be included in nursing education and professional development, the open text responses connect AI education to facilitating CHNs' involvement (participation). Second, the open text responses share a wide range of ways CHNs can be involved. It verifies the importance of including all levels of nurses, specifically noting direct care nurses, and validates that CHNs need to be engaged during all phases of AI. Areas of involvement include: raising relevant questions, planning, development, implementing, evaluation, and monitoring to ensure AI is clinically relevant and accurate. Third, they recognize that their involvement includes regulation, workplace policies, and ethical frameworks to guide their practice because AI is a tool. Fourth, they readily admit to being apprehensive, citing concerns with loss of some of their skills (eg, assessment) along with the human connection and relationship with clients because of AI. This loss of human connection because of technology is also a common concern explored in the literature [49,50]. Further research should continue to examine how CHNs can be better involved.

Clinical Implications and Recommendations

This research reveals 2 interrelated concepts, preparation and participation. These are both essential to better involve CHNs. The first, preparation, acknowledges the importance of education and ongoing professional development. This builds the foundation that will support CHNs to become involved. AI needs to be consciously integrated both in nursing education and ongoing professional development, with attention to a standardized curriculum to ensure all nurses have a basic understanding of AI. Specific areas of concentration should address professional accountability. This will provide CHNs with knowledge to evaluate AI outputs as part of their decision-making, as well as planning and ameliorating perceived future effects of AI. The second, participation, addresses the various aspects of involving CHNs to identify relevant questions and to contribute their nursing perspective to all phases of development and implementation of AI. Professional nursing groups and health care organizations are instrumental in ensuring that the right mix of CHNs, from end user to leadership, have participation on AI advisory committees. Although this research was initiated to examine the perceptions of CHNs about AI in clinical practice, it now raises the necessity of further research to expand on these results by conducting small group consultations to gain an in-depth understanding of how best to involve CHNs.

Strengths and Limitations

The strengths of this study include establishing baseline knowledge and perceptions of AI among Canadian CHNs. An effort was made to recruit the appropriate sample population by targeting national nursing groups as well as provincial and territorial nursing organizations. This survey identifies the need for appropriate education (preparation) and confirms that CHNs want to be involved (participation). It explores the use of the self-reported level of knowledge to determine differences between the "good" and "not good" levels of knowledge.

Several limitations exist. The original survey that was foundational to this study did not have psychometric or reliability testing done. Further testing and reporting of reliability is recommended as a future step. In this variation of the survey, only 1 experienced community nurse was used to determine face validity. A notable limitation of the research is the length of the instrument, as nonresponses increased as the survey progressed. The multiple response questions allowed for several responses, which may have blurred the interpretation. For example, under "current position," a respondent could have 2 different positions within the community, for example, direct care and educator. Self-reported knowledge is subjective; we are unable to verify what the respondents know or do not know or evaluate the expertise of their knowledge. However, CHNs who feel they have knowledge were more favorable or optimistic about AI within their practice. This study did not examine whether respondents had AI-related practical experience or whether current AI is integrated into their practice. Each survey statement or question is briefly explained or described, for example, "AI will revolutionize nursing by supporting health promotion and disease prevention, helping create personalized treatment plans, speeding up administrative tasks." Each respondent could interpret it differently depending on their understanding of how this might occur and their experience with any of the concepts in the descriptor. There were no respondents identified from Prince Edward Island, Saskatchewan, or the Northwest Territories. With a nonresponse rate (42/228, 18.4%) for this question, it could not be determined where the missing respondents were located. An online survey has challenges. The recommended number of 377 respondents to have a 5% error margin was not achieved. The true response rate is unknown because it is unknown how many CHNs received the recruitment invitations due to the method used to recruit respondents. Respondents' bias or selective reporting may have occurred because it was an online survey; only nurses who could access the survey could respond. Additionally, using the term AI in the survey title may have only interested a select group of nurses. As well, the survey was only offered in English, limiting the participation and insights from Francophone nursing colleagues. Lastly, for analysis, the chi-square test can only test for the association of the categorical variables, not causation.

Conclusions

The survey results provide insights into the proposed research questions. Only a third of CHNs are aware that AI is emerging in nursing practice. CHNs use informal sources of knowledge (eg, family and friends) to learn about day-to-day AI applications, with some unaware that these day-to-day

XSL•FO
RenderX

applications are AI-driven. This raises the concern that CHNs may be using AI in their practice without realizing that the technology they are using is AI-based. CHNs who report better AI knowledge tend to be more optimistic (ie, “more exciting”) and less uncomfortable about AI and its effects on practice. However, many CHNs have concerns with AI and their professional accountability. Many CHNs agree that AI as a topic should be included in nursing education as well as professional development. This study identifies that most CHNs want to be involved in AI, highlighting that they want to be consulted and given opportunities to raise nurse-relevant questions. An important step to better involve CHNs should address the availability of appropriate and consistent education. This will help to promote the awareness of AI in nursing and alleviate professional concerns, thus preparing CHNs to be better involved.

Acknowledgments

The authors thank all respondents for taking the time to participate in this research.

Abstract

Background: The majority of patients with diabetic wounds living in Mae Chan District, Chiang Rai Province face challenges such as a shortage of nurses, limited access to health care, and insufficient resources. Strategies such as specialist networks, patient monitoring, and online care platforms are crucial to improving diabetic wound management in the community.

Objective: This study aims to develop telenursing guidelines for caring for patients with diabetic wounds and foot ulcers, and to investigate the effects of telenursing on wound healing among patients.

Methods: Participatory action research was conducted in three cycles: (1) assessing the current situation and feasibility of telenursing; (2) evaluating telenursing guidelines for wound healing; and (3) examining the effects of telenursing on wound healing, amputation rates, and patient satisfaction.

Results: The mean diabetic wound severity scores decreased after receiving telenursing care at weeks 2, 4, 6, and 8 (P<.001). No patients were found to have foot or leg amputations. The patients in the group who received telenursing care showed that their wounds healed in an average of 8.6 (SD 4.3) weeks. The satisfaction score for telenursing care was 4.7 out of 5 (SD 0.2).

Conclusions: Telenursing guidelines were developed to enhance access to wound care, reduce amputation rates, and promote wound healing, resulting in a significant reduction in wound severity and the absence of amputations. The study further demonstrated that telenursing not only expedited healing times but also reduced health care costs and improved patient satisfaction.

telenursing; diabetic ulcers; wound care; nursing guideline; quality of service

Introduction

Diabetes is one of the serious chronic diseases strongly associated with health complications, including macrovascular disease, microvascular disease, peripheral vascular complications, and neuropathy, leading to serious health problems such as coronary heart disease, stroke, kidney disease, and retinal abnormalities. In addition, patients with diabetes are at risk of having foot ulcers, which are the most common complications causing disability, amputation, or premature death. This is one of the most critical public health problems. Diabetic foot ulcers are among the most common complications in persons with diabetes who have problems with uncontrolled blood sugar [1]. The incidence shows that patients with diabetes develop foot ulcers at 19% to 34% and have recurrence symptoms within 3 to 5 years at 65%; moreover, foot or leg amputation is found to be shared among patients with diabetes compared to the general population at 50% to 70%, and they have a chance of premature death within 5 years [2]. Foot ulcers among persons with diabetes take longer to recover than those of normal people, taking an average of 11 to 14 weeks. This could affect the lifestyles of the patients because it causes physical, mental, and social limitations. According to a study of health expenses for caring for patients with foot ulcers in a tertiary university hospital in Singapore between 2013 and 2017, the average cost of wound care alone was US $3368 per patient per year; the cost of minor amputation below the ankle was US $10,468 per patient per year; and the cost of major amputation above or below the knee was US $30,131 per patient per year [3].

Foot ulcers [4,5] can be classified into the following types of wounds. First, infected ulcers are where the wound is infected

XSL•FO
RenderX

and becomes inflamed. The area around the wound is red and spreading from the original site. Symptoms of infected wounds are redness, swelling, pain, and pus. Second, neuropathic ulcers are the most common complication of uncontrolled diabetes. The wound is usually round in shape, with a deep hole in the middle part and thickened skin on the edges. It is found at the base of the big toe and pinky toe. Neuropathic ulcers develop from smaller wounds with symptoms of redness, swelling, numbness, or inflammation around the affected area. Third, ischemic ulcers are wounds that develop when the arteries do not deliver enough blood flow to a specific area, causing local ischemia in the skin and the underlying tissues. Initially, these ulcers manifest as blue discoloration, necrosis, or gangrene. They are painful wounds often found on the tips of the toes, especially the big and pinky toes. The characteristics of the wounds are pale, yellow, and cold, with a weak or absent pulse. They often start at the fingertips and pose an increased risk of amputation if left untreated. Diabetic ulcers are complex and chronic wounds that cannot follow the normal wound-healing process. When the wound is infected, dead tissue (sloughing or shedding) and purulent exudate from inflammation of the wound. There is no new tissue formation, and it does not heal within 4 weeks. Diabetic wounds heal slowly, and sometimes they do not heal. If the wounds are left without proper care, they will cause an infection that will spread to the bone layer (osteomyelitis), requiring organ removal (amputation). If a severe infection enters the bloodstream (septicemia), it can cause death. The essential goals in caring for patients with diabetic ulcers are to prevent disability from the wound spreading to the point where it is necessary to amputate the involved organ, to prevent new wounds from forming after treatment, and to increase the quality of life of the patients.

Diabetic wound care is integral to medical practice to heal wounds better and faster. To promote wound healing faster, (1) clean the wound to prevent infection and promote the wound healing process, (2) keep the wound elevated to reduce fluid accumulation and promote blood circulation, (3) provide adequate knowledge regarding nutrition to promote the wound healing process, (4) have enough rest because resting will reduce the metabolic process inside unnecessary cells and tissues and can carry enough oxygen and nutrients to the wounds, and (5) promote personal hygiene [6]. Diabetic wound care should be supervised by a nurse with clinical expertise who can collect, evaluate, analyze, and identify the needs and problems of patients. Expert nurses should be able to manage options for care and use medical supplies and equipment correctly and appropriately, obtain communication skills to coordinate with the treatment team and encourage family members to participate in care, identify health services and resources, protect patients' rights and privacy, and preserve patient safety and prevent harm during care [7-9]

Despite a community point prevalence of approximately 1.5% to 5% for diabetic foot ulcers, the lifetime incidence risk reaches 19% to 34% [1]. This elevation is frequently linked to suboptimal foot self-care practices; however, there are not enough nurses to meet the increasing demand for care and other issues in Mae Chan District, Chiang Rai Province, such as a lack of health equipment; resources; and access to health services, communication channels for health care advice, and continuity of care rehabilitation. Therefore, strategies for caring for diabetic wounds are necessary, such as creating a network of channels for giving advice from specialists to nurses, caregivers, and patients in the community, monitoring and following up with patients, and providing quality of service through online channels. Various health care advice channels could increase access to services, reduce waiting time, and facilitate patients in a new way of life (New Normal). Moreover, the use of digital technology systems to provide health services for continuous care and referral to primary care units with the best practice guidelines, The Nursing and Midwifery Council has announced telenursing strategies to provide health care advice and to find solutions related to health within the knowledge framework of the nursing and midwifery profession [10].

Telenursing uses information and communication technologies to develop all fields of nursing care, education, and research at a distance [11]. In Thailand, the Nursing and Midwifery Council provides advice and solutions related to health within the knowledge framework by using this digital technology system to provide services and support all forms of nursing care, including continuous care, quality of care, equal access to health, and allowing people to manage their health through online services [10]. Telenursing care increases channel access to health services, covers health care in remote areas, especially in areas with travel restrictions, and maintains professional standards and quality. Patients also do not need to commute to the hospital, which helps reduce the cost of hospital admission and other related expenses while still allowing monitoring and following up on patients' conditions through online channels.

The Mae Chan Hospital is located in the Chiang Rai Province. It is a middle-level hospital that can host up to 120 beds and support referrals from community hospitals in the joint service network of 4 districts: Mae Chan District, Mae Fah Luang District, Doi Luang District, and Chiang Saen District. The Mae Chan Hospital is responsible for caring for patients referred from community hospitals when the capacity of those hospitals in the 4 districts reaches the limit. The hospital helps increase access to treatment for service users in the area, reduces referrals to regional hospitals (advanced-level hospital), and supports primary service units in each district. The Wound and Ostomy Care Clinic, Mae Chan Hospital, provides services for patients with chronic wounds, bedsores, general wounds, penetrating wounds, drains, and ostomy care. Some nurses specialize in diabetic wounds, one specialist in ostomy care, and one in general care for patients. There were a number of people who received services from 2020 to 2022, including a total of 2142, 1571, and 1675 patients, representing 3725, 4931, and 6239 visits, respectively. There were 114, 70, and 67 patients with diabetic ulcers, accounting for 405, 281, and 291 visits, respectively. The average cost of commuting to the hospital for patients to receive wound care is US $10 per time. The average number of days to receive wound care services is 14 to 45 days per person. In general, the travel distance for patients to visit the wound care and ostomy clinic is 1 to 40 km. Due to travel distance and expenses involved in wound care at the hospital, some of the patients are unable to receive treatment regularly

XSL•FO
RenderX

and continuously, so many patients experience wound spreading and recurrence of wound infection, leading to foot or leg amputation in some cases.

According to literature reviews, telenursing is important in assisting patients to access standard care for chronic wounds. Telenursing care helps reduce complications and the number of patients admitted to the hospital, which encourages participation among patients, caregivers, and nurses in self-care practices, and increases patient satisfaction because it reduces travel time, traveling costs, and other related expenses of going to the hospital. Therefore, the research team was interested in studying the development of telenursing guidelines for caring for patients with diabetic wounds and foot ulcers, and the effects of telenursing on wound healing in patients to provide quality service and prevent the spread and recurrence of wound infections and foot and leg amputations in patients.

Methods

Study Design

This was participatory action research [12], which divided the study into 3 cycles.

Cycle 1

The current situations, problems, and needs of patients with diabetic wounds and the feasibility of using telenursing guidelines in the context of the Mae Chan Hospital, Chiang Rai Province, and community networks in the research area were studied. The researcher used lessons learned from the study to conclude the issues and needs of developing and drafting telenursing guidelines for diabetic wound care. Informants and participants in the design of diabetic wound care guidelines and telenursing system were purposively selected, consisting of (1) patients with diabetic wounds and/or their caregivers who received care in the Wound and Ostomy Care Clinic, totaling 10 persons; (2) the multidisciplinary team including a surgeon, a pharmacist, a nutritionist, and 9 registered nurses at subdistrict health-promoting hospital in the Mae Chan Hospital networks, totaling 12 people; and (3) a computer technical officer.

The interprofessional team plays a critical role in providing comprehensive care for patients with chronic diabetic wounds. The surgeon is central to diagnosing the underlying causes of chronic wounds, determining their etiology, and formulating an integrated treatment plan. In collaboration with the health care team, the surgeon ensures the effective implementation of telenursing guidelines, addressing the needs of patients who face barriers to in-person health care access. The pharmacist works closely with the physician and nursing staff to select appropriate topical treatments that promote wound healing and minimize the risk of infection. In addition to this, the pharmacist is responsible for educating both patients and their families on the proper use of medications and wound care techniques. The nutritionist plays a vital role by recommending dietary strategies that support wound healing, promote tissue regeneration, and address underlying risk factors such as poor circulation or diabetes. Their tailored nutritional guidance is designed to strengthen the immune system and accelerate recovery. Finally, the computer technical officer ensures the seamless operation of the telemedicine system, facilitating smooth communication via platforms like the "Wound Care Mae Chan" LINE app. They provide technical support, enabling real-time updates and enhancing the overall telehealth experience for both health care providers and patients.

Cycle 2

Telenursing guidelines toward diabetic wound healing were studied. Participants recruited in the study were patients with diabetic wounds and professional nurses from subdistrict health-promoting hospitals under the Mae Chan Hospital network, totaling 20 persons. A sample size calculation was done using G*Power software version 3.1.9.4 (Fual et al), with test power set at 0.70, confidence value at 0.05, and influence value (effect size) at 0.30. The number of samples obtained from the calculation was 13. An additional 50% was added to the sample size, so the total number of participants in this cycle was 20.

Cycle 3

The effects of telenursing on diabetic wound healing were studied by evaluating the wounds, foot or leg amputation, and satisfaction with using telenursing guidelines. A quasi-experimental one-group pretest-posttest design was employed in this stage of the study.

Research Instruments

The tools used for data collection are given below:

1. General information on characteristics was collected, including gender, age, education level, occupation, history of smoking, history of diabetes and duration, and types of diabetic wounds.
2. Bates-Jensen Wound Assessment Tool (BWAT): the BWAT consists of 13 wound characteristics: size, visible depth, wound edges, undermining and tunneling processes, necrotic tissue type and amount, exudate type and amount, surrounding skin discoloration, peripheral tissue edema, peripheral tissue induration, granulation tissue, and epithelialization [13]. The scores range from 13 to 65, and content validity and concurrent validity are both equal to 0.91. The assessment tool was used in a tryout among 10 patients with similar characteristics to find reliability using the Cronbach α coefficient formula, and the reliability value was 0.88. The cutoff scores of BWAT are the following: minimal scores are 13 to 20, mild severity scores are 21 to 30, moderate severity scores are 31 to 40, and critical severity scores are 41 to 65.
3. The questionnaire on satisfaction with the telenursing guidelines consists of 7 items rated on a 5-point Likert scale measuring satisfaction, with response options ranking from 5 (very satisfied), 4 (satisfied), 3 (neutral), 2 (dissatisfied), and 1 (very dissatisfied).

The tools used to conduct the study included the following:

1. Guidelines for diabetic wound care: the researcher developed the guidelines based on the existing literature review by specifying keywords to search for papers and related documents, including diabetic wounds, chronic wounds, guidelines for wound care, and wound care. The

XSL•FO
RenderX

literature review search period was set from 2014 to 2023. Information was also obtained from cycle 1, which involved studying the current situations, problems, and needs of patients with diabetic wounds and the feasibility of using telenursing guidelines. The researcher presented a draft of telenursing guidelines to 3 experts in the fields of surgery, preventive medicine, and wound and ostomy care. These experts reviewed the guidelines to ensure they were consistent with the research objectives. Content validity was performed by measuring the Index of Item Objective Congruence, which was equal to 0.80.

2. LINE app "Wound Care Mae Chan"
3. Telemedicine Service System (Telemedicine; ITELE) of Mae Chan Hospital

Ethical Considerations

The Human Research Ethics Committee at Chiang Rai Provincial Public Health Office approved this research study under approval 37/2023, with certification granted on April 1, 2023. The researcher adhered strictly to ethical principles throughout the study. Before participation, the researcher clearly communicated the objectives of the study, the research process, the expected duration, and the anticipated benefits to ensure a full understanding; subsequently, written informed consent was obtained from all participants before any data collection commenced. Informants and participants were informed that communication regarding wound care would be conducted via the LINE application, specifically designated for this research group. They were also informed of their right to withdraw from the study at any time, without any impact on their current treatment or benefits received from the hospital.

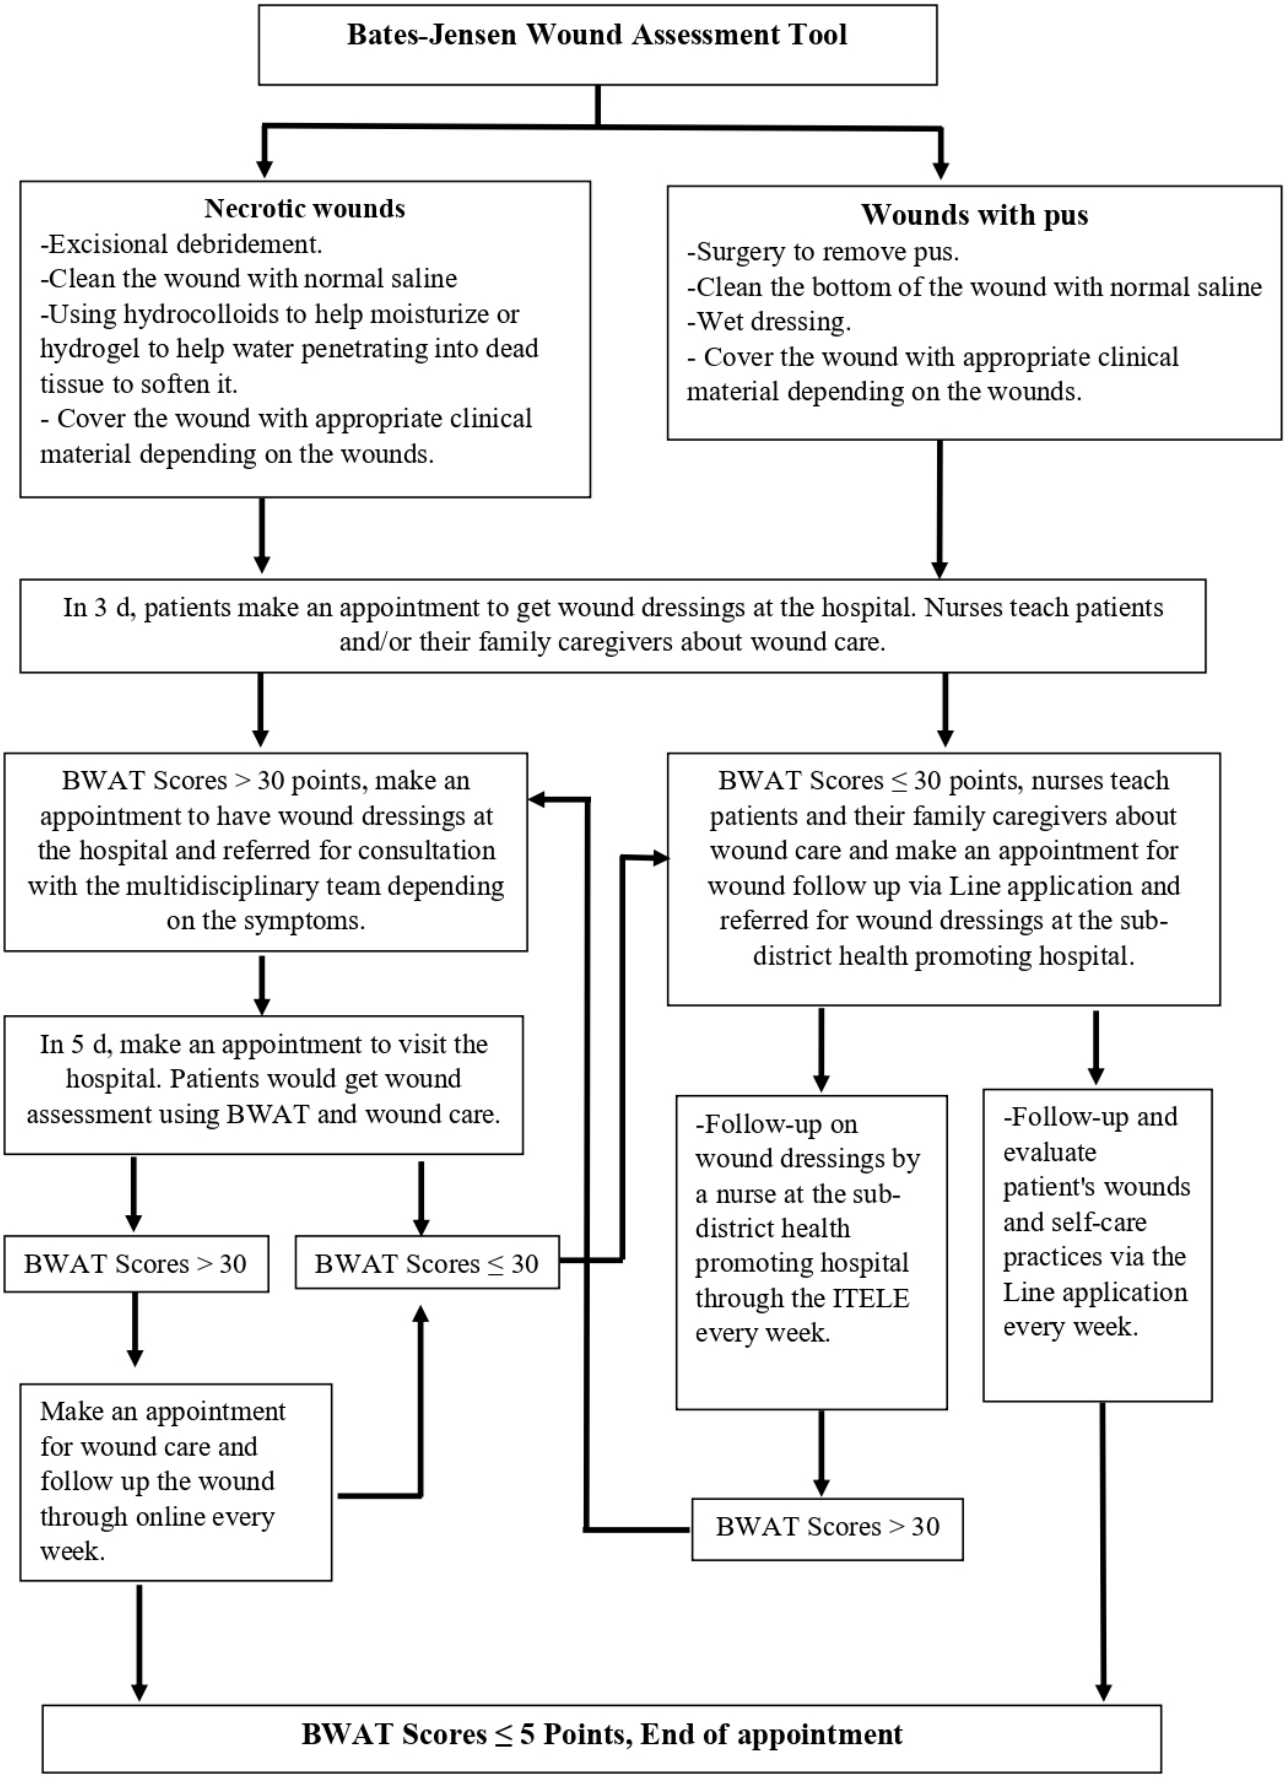
Participants received a remuneration of US $6 for each completed data collection session. The researchers were committed to protecting the participants' rights and privacy. As such, all data were recorded using codes instead of real names, ensuring anonymity. All participant information was kept confidential and could not be traced back to any individual. The findings of the study were presented as aggregated data to protect participant identity. Furthermore, all recorded data, including images, would be destroyed 1 year after the publication of the research results.

Results

As per the study objectives, we developed telenursing guidelines for caring for patients with diabetic wounds and foot ulcers, and studied the effects of telenursing on wound healing, using participatory action research.

In cycle 1, to study the current situations, problems, and needs of patients with diabetic wounds and the feasibility of using telenursing guidelines, we recruited 10 informants who were patients with diabetic wounds and foot ulcers aged between 30 and 74 years (average age 62.6, SD 12.4 years; duration of diabetes 1-10 years; average duration of diabetes 4.9, SD 3.5 years; average wound assessment score 51.3, SD 3.3); additional informants included a surgeon, a pharmacist, a nutritionist, 9 registered nurses at the subdistrict health-promoting hospital, and a computer technical officer. The following needs and problems were found.

Some patients could not receive wound care regularly and continuously because of the distance to the hospital, traveling difficulties, expenses for transportation, food, medical care, and related costs. Findings showed that some patients live far from the hospital. It costs them a lot of money per hospital visit. In some cases, patients have no one to take them to the hospital because family members have to work, and if they have to accompany the patients to the hospital, they have to miss their work and lose income. Moreover, they must spend extra money on transportation and food while waiting for patients to receive wound care. The cost of traveling to the hospital to receive wound care services is approximately 100 to 1000 Baht (US $2.85-$28.50) per visit, which is too much for them to spend, especially for patients and their family members who live in a remote community area.



Lack of knowledge about diabetic wound care is one of the problems. Patients lack adequate knowledge of wound care, nutrition, and control of blood sugar levels. These are factors for wound healing. In some cases, patients did not follow up on the appointment, which could also affect their physical health. Because of this, many patients experienced wound spreading and recurrence of wound infection, and in some cases, may experience foot or leg amputation.

Treating severely infected wounds requires skills and expertise in advanced wound care, which exceeds the potential of community nurses working in subdistrict health-promoting hospitals, and patients did not have access to or resources for advanced wound care, such as hydrocolloid, hydro fiber, alginate, hydrogel, foam, and film dressings.

Nowadays, the majority of patients and their family caregivers have smartphones that can be used to communicate via the LINE app. Introducing telenursing for diabetic wound care among patients could help reduce barriers to receiving health care services. Based on the study of situations, needs, and problems among patients with diabetic wounds, telenursing guidelines for diabetic wound care are summarized as shown in Figure 1.

Figure 1. Telenursing guidelines for diabetic wound care. BWAT: Bates-Jensen Wound Assessment Tool; NSS: normal saline solution.

In cycle 2, the telenursing guidelines for diabetic wound healing were evaluated.

The study sample included 20 patients with diabetic wounds and foot ulcers, and half of them were female (n=10, 50%) and

XSL•FO
RenderX

aged 30 to 81 years, with an average age of 47.6 (SD 9.4) years and an average duration of diabetes of 7.6 (SD 6.4) years. Studies showed that the wounds were found most on the leg, foot, and toe (n=15, 75%). The average assessment wound severity score was 50.8 (SD 4.4), indicating that patients had wound critical severity (BWAT=41‐65 points represents critical severity), and the results are shown in Table 1.

[a]BWAT: Bates-Jensen Wound Assessment Tool.

The researcher prepared workshops and set up a meeting to explain the task of developing telenursing guidelines to the committee and those responsible for the continuous care, advanced wound care, and training program using the ITELE.

In cycle 3, mean wound severity scores were compared before and after receiving telenursing guidelines for diabetic wound care at week 2, week 4, week 6, and week 8 using 1-way repeated measures (ANOVA) statistical analysis; the results are shown in Table 2. The mean scores for wound severity were significantly different at the .001 level. A comparison of the wound severity scores before and after receiving telenursing nursing care guidelines for wound care at week 2, week 4, week 6, and week 8 using *t* test (1-tailed) statistical analysis is shown in Table 3.

XSL•FO
RenderX

Table . Comparison of the wound severity scores before and after receiving telenursing guidelines toward diabetic wound care using repeated measures of 1-way ANOVA statistics.

ANOVA	Sum of square	*df*	Mean square	*F* test	*df*	*P* value
Between-group	15,379.4	4	3844.8	401.7	4	<.001
Within-group	3360.2	95	35.4	—[a]	95	—
Total	18,739.6	99	—	—	99	—

[a]Not applicable.

Table . Comparison of the wound severity scores before and after receiving telenursing guidelines towards diabetic wound care at week 2, week 4, week 6, and week 8.

	Wound severity scores, mean (SD)	*t* test (*df*)	*P* value
Before and after receiving telenursing care guidelines for diabetic wound care in the second week	23.7 (5.3)	20.0 (19)	<.001
Before and after receiving telenursing care guidelines for diabetic wound care in the fourth week	29.6 (3.9)	34.3 (19)	<.001
Before and after receiving telenursing care guidelines for diabetic wound care in the sixth week	32.0 (4.0)	35.3 (19)	<.001
Before and after receiving telenursing care guidelines for diabetic wound care in the eighth week	34.0 (4.7)	36.1 (19)	<.001
After receiving telenursing care guidelines for diabetic wound care in the week 2 and week 4	5.9 (3.9)	6.8 (19)	<.001
After receiving telenursing care guidelines for diabetic wound care in the week 2 and week 6	8.3 (5.0)	7.4 (19)	<.001
After receiving telenursing care guidelines for diabetic wound care in the week 2 and week 8	10.3 (6.5)	7.1 (19)	<.001
After receiving telenursing care guidelines for diabetic wound care in the week 4 and week 6	2.4 (2.6)	4.1 (19)	<.010
After receiving telenursing care guidelines for diabetic wound care in the week 4 and week 8	4.4 (3.9)	5.1 (19)	<.001
After receiving telenursing care guidelines for diabetic wound care in the week 6 and week 8	2.0 (2.3)	3.8 (19)	<.010

According to Table 3, the wound severity scores after receiving telenursing care in the 2nd, 4th, 6th, and 8th weeks had decreased statistically (*P*<.001). The scores after receiving telenursing care in weeks 4, 6, and 8 had decreased statistically from week 2 (*P*<.001). The scores after receiving telenursing care in weeks 6 and 8 had decreased statistically from week 4 (*P*<.001), and the scores after receiving telenursing care in week 8 had decreased statistically from week 6 (*P*<.001).

Discussion

Principal Findings

The findings of this study showed that samples had a mean age of 62.6 (SD 12.4) years, an average duration of having diabetes for 4.9 (SD 3.5) years, and high levels of wound severity on average (BWAT=50.8, SD 4.3). This indicates that the majority of the sample were older people, who have a high risk for critical wound severity. First, the factors affecting the wound healing process include infection, high blood sugar levels, and nervous system disorders. This is consistent with the study by Burgess et al [14], which found that the pathophysiology related to the diabetic wound healing process includes hyperglycemia, neuropathy, microvascular complications, infection, inflammation, and immune system deficiency in chronic wounds, and the psychological impacts of diabetes mellitus. Second, the factors preventing patients from receiving wound care continuously include financial limitations, distance to the hospital, no caregivers taking them to the hospital, and so on.

XSL•FO
RenderX

From the in-depth interviews, it was found that the majority of patients live far from the hospital. Distance is one of the barriers to accessing health services. Some patients do not have anyone to care for because family members have to work. Due to this reason, some of the patients are unable to go to the hospital by themselves. If a caregiver comes to the hospital, it would cost more money for traveling expenses, which is more than the net income received each day. The average cost is US $6 to US $10 per time, which is considered a high expense. Third, the knowledge factors where the patient does not have enough knowledge regarding blood sugar control and nutrition, which are important factors to promote wound healing. The problems and needs of patients led to the development of telenursing guidelines to provide patients with access to wound care services to prevent leg or foot amputation, increase the rate of wound healing, reduce wound healing time, reduce inequality, and distribute opportunities to access advanced wound care and resources for wound healing.

A study of the development of using telenursing guidelines on diabetic wound healing found that the mean wound-based severity scores had decreased significantly after receiving telenursing guidelines for diabetic wounds in week 2, week 4, week 6, and week 8 ($P<.001$). Moreover, no patients were found to have foot or leg amputation. This can be explained by the fact that the samples in this study received baseline assessment, including illness history, duration of the wound, history of received medicine, financial status, nutrition, and wound assessment using the BWAT. Patients also received wound assessment every week from the beginning throughout the study. Having regular wound assessments is important for effective wound care. Understanding factors affecting wound healing helps nurses make appropriate decisions in wound care [15]. This allows the wound healing process to proceed normally, and it works well together by preparing the wound to be in an appropriate state according to the principles of wound bed preparation [16]. Wound management consists of three phases. First, the debridement of the wound is when dead or unhealthy tissue is removed from a wound. It stimulates wound healing to the proliferative phase, causing re-epithelialization of the wound to be smaller, which prevents or reduces the amount of infection by removing pathogenic parts such as foreign bodies. Second, the wounds are made moist by dealing with secretions, making the wound healing more effective and causing angiogenesis, the formation of granulation tissue, and the process of re-epithelialization. Third, the wound infection is controlled by cleaning the wound to reduce the number of germs and giving topical antibiotics [17,18].

Information for developing telenursing guidelines was obtained from studying the situations, problems, and needs of patients with diabetic wounds and foot ulcers, as well as from reviewing the existing literature. Based on the information, self-care behaviors are important for promoting wound healing among patients, such as controlling blood sugar levels, taking care of the wound by cleaning and getting wound care regularly and continuously, and eating proper food with good nutrition. According to this study, the patients in the group that received telenursing care could heal wounds in an average of 8.6 (SD 4.3) weeks. The patients in the group that received advanced wound care and normal wound care could heal their wounds in an average of 10.2 weeks. The patients in the group that received wound care every day (conventional wound dressings) and normal wound care could heal in an average of 11.72 weeks. The average cost of wound care for the group receiving telenursing guidelines was 11,772 Baht (US $336.34) per person, receiving advanced wound care and normal care was 14,772 Baht (US $422.06) per person, and receiving wound care and normal care every day was 22,740 Baht (US $649.71) Baht per person. In terms of the average score of satisfaction using telenursing guidelines, it was 4.7 out of 5 (SD 0.2). This is consistent with many studies stating that self-care behaviors, blood sugar level control, and continuous use of medication among patients with diabetes were better after telenursing care [19-22], and this reduces the use of resources for treating diabetic wounds, hospital admissions, and patient expenses while maintaining service quality [19,23-26].

This research is in alignment with both national and international policies that promote the incorporation of digital technology as a tool for enhancing health care services. It also functions as a conduit, bridging the gap between communities and health care systems, thereby mitigating geographical and relational disparities between the public and health care providers. Moreover, digital technology empowers individuals to stay informed about evolving health conditions, understand their rights to access high-quality, equitable, and safe health care, and fosters public awareness and collaboration in improving personal and community health outcomes [27,28].

Suggestions for Using Research Results

To continuously produce good results when implementing telenursing guidelines for improving the quality of services in diabetic wound care, those involved in the development process, including community people, patients, health care providers, nurses, health staff, and family caregivers, must be prepared in terms of knowledge in the field of diabetic wound care such as advanced wound care, the ITELE program, community nursing, self-care practices and knowledge regarding the use of remote technology in accordance with the steps of the nursing process, and health assessment, including defining problems, planning, practice, and evaluation.

There must be supervision, monitoring, and evaluation of the use of telenursing guidelines to improve nursing practices suitable to the community context and in accordance with knowledge about advanced wound care, diabetic wounds, chronic wounds, and remote technology.

Limitations

The small sample size limits the ability to generalize the findings to a broader population.

The JMIR Publications Editorial Office is retracting the article "Comparative Effectiveness of Health Communication Strategies in Nursing: A Mixed Methods Study of Internet, mHealth, and Social Media Versus Traditional Methods" by Hamarash et al [1]. This follows an investigation that identified concerns regarding the integrity of the peer-review process that occurred for this article. We regret that these issues were not identified prior to publication.

All authors did not agree with retraction.
